Ground-colour of the head and body light green; abdomen greenish white; on the upper part of the head some vermillion spots; a broad vermilion band edged with deep blue from the eye to the angle of the mouth; a second obliquely over the cheek towards the angle of the mouth; a third on the preopercle; a fourth on the temple round the eye; a fifth along the upper margin of the opercle; a sixth, angular, on the upper half of the opercle; on the lower half a large vermilion spot; a seventh on the subopercle; each of the scales of the back and sides with a large central vermilion spot; in front of the vermilion root of the pectorals a large dark-blue spot; pectorals hyaline, the rest of the fins pale yellowish green; dorsal with a series of oblique vermillion lines along the base; a central brownish-lilac undulating line between the five first spines; between the fifth and sixth a large dark-blue spot; between the succeeding spines and rays a large triangular brownish lilac spot occupying the upper half of the membrane; upper margin vermillion; angles of the caudal with a triangular orange spot with a basal vermillion line; two indistinct vertical brownish bands in the middle, the whole fin with numerous small blue spots; anal with a series of oblique vermillion lines along the base; upper half brownish lilac, the three spines with vermillion points; first and second ventral rays vermillion. Iris narrow golden, next vermillion, orbital margin brownish green with a vermillion spot at the lower half. D 9/12, C 14½, A 3/12, V 1/5, P 16, Br. V. Inhabits *Sea of Pinang*, Malabar. Total length 4⅝ inch. The length of the head is 4½ in the total. The eye occupies the third-fifth of the head, and the upper third of the vertical diameter passes through it; the horizontal diameter is ⅕ of the length of the head. The greatest vertical diameter of the body equals the length of the head. The tooth on each side of the symphysis of the upper jaw is longer than the succeeding seven of the external series, which gradually decrease in length. At the angle of the mouth at some distance from the last tooth appears a strong obliquely downwards and forwards pointed tooth. Two teeth on each side of the symphysis of the lower jaw are longer than the rest, which are smaller than the corresponding ones of the upper jaw. The scales of the body are large, striated. A longitudinal series contains 26, an oblique 11. The lateral line consists of tubes, each with a smaller superior and an inferior tube branching off backwards. The anterior part of the line rises obliquely towards the sixth dorsal spine, the rest proceeds straight along the upper fourth of the body towards the ninth ray, when it declines a little and proceeds straight towards the caudal. The posterior margin of the latter fin is rounded. The last ray of the dorsal and the anal, and the first ray of the ventrals are elongated into a very short filament. The anterior anal spine is very minute. The figure of M.M. Cuvier and Valenciennes does not quite correspond to their very correct description. A single individual occurred at Pinang in June 1844.

(3809) *Julis mola*, Cuvier.

Syn. Russell, CXX. Sahnee Moia.
Julius mola, Cuvier, R. A. II. 258.
Sahnee moia, Cuv. an Val. XIV. 234.

Ground-colour of the head and body pale sea-green; abdomen whitish green; from the muzzle over the forehead along the base of the dorsal a dark brown longitudinal band; a second from the side of the muzzle through the eye along the middle of the side to the root of the caudals; the two bands in some consisting of two or three series of spots; on the upper part and sides of the head some irregular orange streaks: pectorals hyaline, red at the root; ventrals white; rest of the fins pale yellowish green; dorsal with an undulating pale blackish band along the base and a second along the middle; in some a black spot either between the fifth and seventh spine, or between the first and second; caudal with some pale bluish spots, and in some with a black spot at the root, and with pale blackish spots near the margin. Iris narrow golden, next vermillion; orbital margin dark brown. D 9/12 C 14⅔, A 2/12, V 1/5, P 15, Br. V. Inhabits *Sea of Pinang*, Coromandel. Total length 4⅘ inch. The length of the head is 3¾ in the total. The diameter of the eye, situated as in *J. dussumieri*, is ⅕ of the length of the head. The dentition and scales resemble those of the latter species. A longitudinal series contains 27, an oblique 13 scales. The lateral line proceeds straight along the upper fourth of the body towards the ninth dorsal ray, from whence it declines towards the middle of the side and proceeds straight towards the caudal. The line is composed of tubes, from each of which, anterior to the ninth dorsal ray, branch off backwards a superior and inferior smaller tube.

The greatest vertical diameter of the body equals the length of the head. The first seven dorsal spines are shorter than the rest, which makes the anterior part of the fin lower than the posterior. The stomach is a short elongated tube, slightly more voluminous than the intestinal canal which is thrice doubled upon itself. The length of both is $\frac{1}{3}$ of the total. The air-vessel is small, elongated conical, of a silvery colour. Single individuals occur, but rarely, at Pinang.

Genus SCARUS, Gronov. 1763. Jaws (intermaxillary and premandibular bones) convex, rounded, with teeth, arranged like scales, on their edge and anterior surface; lips single, fleshy; body oblong with large scales; lateral line interrupted; one inferior and two superior pharyngeal plates with teeth like transverse laminæ,

(3810) *Scarus psittacus*, Forskal.

Scarus psittacus, Forskal 29.
Scarus psittacus, Shaw, IV. 397.

Petronason psittacus, Swainson, II. 226.

Young. Head above and ground-colour of the back and sides greenish light-blue; all the scales of the latter parts with broad orange margins, forming a net-work; cheeks, opercles, throat and abdomen reddish white; upper lip surrounded by a light blue streak; a second similar from the angle of the mouth obliquely upwards surrounding the lower half of the orbit; a third from the chin to the cheek; a fourth at the anterior margin of the preopercle obliquely backwards over the opercle; a fifth along the posterior margin of the preopercle; from the orbit radiate two upwards and two backwards; in front of the pectoral at the margin of the gill-opening an irregular, light blue spot; dorsal reddish orange; rays, upper and basul margin light blew; caudal membrane yellowish brown, base, upper, lower and posterior margin as well as the rays light blue; anal reddish orange, base and lower margin light blue; spine and point of the ventrals light blue; anterior half of the membrane orange, posterior half white? pectorals yellowish white, second ray light blue. Iris narrow golden round the pupil; rest greenish olive. D 9/10, C 13$\frac{3}{5}$, A 3/9, V 1/5, P 15, Br. V. Inhabits *Sea of Penang*, Red Sea. Total leagth: 10$\frac{4}{5}$ inch. The length of the head is 3$\frac{3}{4}$ in the total. The horizontal diameter of the orbit is 4$\frac{1}{2}$ in the length of the head. The verticle diameter at the occiput equals the length of the head; the greatest verticle diameter of the body sightly exceeds the length of the head. The body is covered by eight longitudinal series, each containing 23 scales. The lateral line consists of backwards branching tubes. The line continues on the third longitudinal series to the termination of the dorsal fin; a single tube then appears on the succeeding scale of the fourth series; the completing part of the line occupies the five posterior scale of the fifth longitudinal series. This species greatly resembles *Scarus harid*, Forskal, from which it differs in having the outline of the abdomen much more convex than that of the back, and in having the angles of the caudal much less elongated. The first of the undivided anal rays is very short and so closely adhering to the second, that it easily may escape observation. A single individual occurred at Pinang in May 1844.

Fam. GLYPHIDODONTIDÆ.

Genus TETRADRACHMUM, *Cantor*. [Τετραδραχμον, a coin, worth four drachms. Substituted for *Dascyllus*, Cuvier, 1829, re-occupied by *Dascillus* (scrib. *Dascylus*,) Latreille, 1796, (*Coleoptera*).] (*Equivalent to* Dascyllus, *Cuvier*.) Shape oblong; head obtuse; teeth velvety, the external series stronger than the rest, conical, pointed; preopercle toothed, lateral line terminating opposite the soft part of the dorsal fin; branchiostegous rays five.

(3811) *Tetradrachmum arcuatum*, (Linne).

Alternately black and white; the anterior band black, occupying the space from the throat to the third dorsal spine, excepting the forehead, from between the eyes to the lips, which is white; next a second oblique whitish band bordering upon the root of the ventrals and the pectorals, and continuing along the sixth dorsal spine; next a black band, comprising the ventral fins to a little in front of the anus, over the sides, and over the seventh, eighth and ninth dorsal spine; next a whitish band from the second anal ray, not comprising the spiny portion which is black, over the body along the first dorsal ray; next a nearly

vertical black, comprising the rest of the anal rays, the anterior half of the narrow part of the body in front of the caudal, and the rest of the dorsal rays; the rest of the space in front of the caudal is whitish, the anterior half of the latter fins is black, the rest paler or grey; pectorals bluish-or greyish-white. Iris narrow silvery round the pupil, the rest bluish black. D 12/12, C 15$\frac{1}{6}$, A 2/12, V 1/5, P 16, Br. V. Inhabits *Sea of Pinang*, South Sea, Timor, Amboina, Indian Ocean, Bay of Bengal, Red Sea. Total length: 2$\frac{1}{8}$ inch. Three individuals were observed at Pinang from 1842 to 1845.

Genus. GLYPHIDODON, (*Forskal.*) *Lacepede*, 1802. Body compressed oval, and as well as the head covered with large scales; profile rounded; mouth small; teeth in the jaws in a single series, close, equal, narrow, trenchant and frequently notched; preopercle not toothed; lateral line terminating opposite the last dorsal ray.

(3812) *Glyphidodon rahti*, Cuv. and Val.

Glypisondon rahti, Bleeker: Verh. Bat. Gen. XXI. 1 Ged. pp. 2, 3, 5.

Upper part of the head and the back as far as the dorsal fin greenish or bluish-black, rest of the back and upper half of the sides greenish yellow or gamboge, lower half of the sides, abdomen, cheeks and opercles bluish silvery, all the scales with blackish margins. In front of the dorsal a vertical black band; a second from between the six and seventh dorsal spine; a third from the posterior spines; a fourth from the soft dorsal fin; a fifth in front of the caudal; scales between the dorsal spines and rays yellow or greenish, membrane blackish-blue with a broad black margin; the scaly base of caudal yellow, the rest greenish-or blnish-black with a broad black posterior margin; in some a broad vertical black band behind the base, and the upper and lower margin black; the scaly base of the anal bluish silvery, the rest bluish black or grey; pectorals transparent bluish white, with a black spot of the upper part of the root. Iris golden near the pupil, the rest blue or black. D 13/13 or 12, C 15?, A 2/12, V 1/5, P 18 or 19, Br. VI. Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore*, New Guinea, Celebes, Java, Ceylon, Bay of Bengal, Bombay, Red Sea. Total length: 6 inch. Not only are the ground colours liable to individual variations according to the yellow or bluish being the prevailing, but the verticle bands are broader or narrower, and the three middle ones are in some continued over the dorsal fin. In some the black bands are very indistinct or almost obliterated, as in the one figured by Russell, No. LXXXVI. in others a few distant black spots appear on the opercles and between the bands (*Chætodon tyrwhitti*, Bennett); the black spot of the pectorals is absent in some, in others it is a continued line along the root of the fin. All ages are subject to these variations. Young individuals are numerous at Pinang at all seasons, but adult ones are seldom seen. They are eaten by the natives.

SUBORDER PHARYNGOGNATHI MALACOPTERYGII.

Fam. SCOMBERESOCIDÆ.

Genus BELONE, *Cuvier*, 1817. Jaws forming an elongated beak, the upper part principally composed of the intermaxillaries, the base of the maxillaries; teeth in both jaws, those of the internal margin longer and more distant than the rest; those of the external margin small, pointed and closely set; lips none; under the symphysis of the lower jaw a short, soft, fleshy appendage; with one exception, no teeth on the vomer; pharyngeal teeth small conical; body elongated with small scales; bones of the skeleton green.

(3813) *Belone annulata*, Cuv. and Val.

Syn. Russell, CLXXV. Mahlah Kuddera.
Belone annulata, Cuv. and Val. XVIII. 447, Pl. 550.
Toda of the Malays.

Adult. Head above and back sea-green with steel-blue reflections, minutely dotted with black; lighter, silvery, on the upper half of the sides; lower half and abdomen silvery white; cheeks and opercles silvery; side of the upper mandible blackish olive, of the lower silvery, with a black line from the angle of the mouth along the base of the teeth; dorsal, caudal and pectorals membranes pale greenish grey, minutely dotted with black, particularly towards the margins; anal and ventrals white, their anterior part minutely dotted with black. Iris silvery, orbital margin black. *Young.* Head and back olive green; above the lateral line a narrow greenish silvery longitudinal band; opercles with a large black spot; lower mandible black; posterior two-thirds of dorsal black; on the middle of the caudal a large black spot. D 22 or 23, C 15$\frac{5}{8}$ A 21 or 22, V 6, P 13 or 14 Br. XV. *Young*: XIII?) Inhabits *Sea of Pinang, Malayan Paninsula*, Seychelles, Tongatabu, Celebes, Pondicherry, Vizagapatam. Total length: 2 ft. 6

inches. The young differs from the adult not only in colours, but in relative dimensions. In an individual, 6⅝ inches in length, the head is 3¼ in the total. The verticle diameter at occiput is ⅙ of the length of the head. The horizontal diameter of the eye is 7½ in the head, measured from the symphysis of the lower mandible, and 2¾ in the distance from the anterior margin of the orbit. The distance across the forehead is a little less than the diameter of the orbit. The posterior rays of the dorsal fin exceed by about ⅓ the length of the anterior ones. The abdomen crest is barely distinguishable. The tongue is fleshy, naked. In another, 11 inches in length, the head is a little more than 3⅛ in the total; the vertical diameter at occiput is 5½ in the head; the horizontal diameter of the eye is 8¼ in the head, measured from the symphysis of the lower mandible, and ⅓ of the distance from the anterior margin of the orbit; the distance across the forehead slightly exceeds the diameter of the orbit; the posterior dorsal rays exceed by ⅙ the anterior ones; the abdominal crest is distinct, particularly on the posterior fifth of the body; the margin of the tongue is studded with two or three series of minute polygonal bony plates, placed beside each other like mosaick; the black spots of the opercles snd caudal are no longer visible. In an individaul, 2 ft. 3 inches in length, the length of the head is 3½ in the total; the vertical diameter at occiput is ½ of the head; the horizontal diameter of the eye is ⅛ of the length of the head from the symphysis of the lower mandlble, and 3⅓ in the distance measured from the anterior margin of the orbit; the distance across the forehead exceeds by ⅓ the diameter; the posterior dorsal rays, although somewhat elongated, are but ½ the length of the second rays. [The figure of Russell is in this respect correct; but the last dorsal ray is placed too near the caudal. The distance between the two fins exceeds by ⅓ the length of the last dorsal ray.] Immediately in front of the caudal the abdominal crest is very sharp, but becomes less so at its termination on the anterior third of the caudal. The hyoid bone and the tongue are entirely covered with a mosaick of small polygonal rough bony plates. The internal surface of the lower mandible presents a structure, which if present in other species, has not been described. The middle where the two branches join each other, is raised and forms a bony ridge, commencing behind the symphysis and gradually widening towards its termination in front of the apex of the tongue. The upper surface of this ridge is flattened, but made uneven by numerous transversal sharp bars, or rather by one continued closely waved bar, forming a kind of grate. The ridge is separated from the teeth by a deep groove, intervening on each side, and is covered by the fine membrane lining the rest of the cavity. In the young it differs by having a comparatively smaller number of transversal bars. The corresponding surface of the upper mandible is smooth, with a longitudinal fissure. In the adult fish the two anterior branchiostegous ray are so very minute, that they may easily escape observation; in young ones they appear to be absent. At Pinang this species is numerous at all seasons, but large individuals are scarce. In several examined, both of the present and the following species, the stomach contained nothing but thick mucus. The fish is eaten by the natives, although it is very insipid.

(3814) *Belone caudimacula*, Cuvier.

Syn. Russell, CLXXVI. Kuddera A. *
Belone caudimucula, Cuv. R. A. 282 (2)
Belone caudimacula, Cuv. and Val. XVIII. 452.
Belone caudimacula, Bleeker: Verh. Bat. Gen. XXII. 5,
Toda of the Malays.

Head above and back yellowish green minutely dotted with brown; lighter, silvery on the sides; posterior half of the latter with a deep-blue longitudinal band, bordered beneath by a broader shining silvery one; abdomen white; sides of mandibles, cheeks and opercles silvery; dorsal, and in some the anal bright yellow, minutely dotted with brown along the rays; caudal yellow or greenish, minutely dotted with black, with a rounded bluish black spot in the centre near the root; ventrals and pectorals hyaline, the latter in some with a black spot along the root. Iris silvery, orbital margin bluish black. D 13, C 15⅔ A 16, V 6, P 10, Br. XII? Inhabits *Sea of Pinang, Malayan Peninsula*, Bombay, Aleppee (in fresh water), Coromandel, Gangetic estuaries. Rangoon, Canton, River Brunai (Borneo), Port Essington, North Australia. Total length: 1 ft. 1 inch. In an individual of the length given the head was contained 2¾ times in the total length. The vertical diameter at occiput was ⅕ of the length of the head. The horizontal diameter of the eye was 10½ of the length of the head, measured from the symphysis of the lower mandible, and ¼ of the distance from the anterior margin of the orbit. The abdominal crest becomes most distinct on the tail. The internal series of long sharp teeth appear proportionally shorter in this than in the preceding species. The tongue is smooth. On the inside of the lower mandible is a bony, grated ridge like that of the preceding species, and *Belone cancila* (Buchan. Ham.) is provided with a similar. Single individuals, all of nearly equal length, occur at Pinang at all seasons. They are eaten by the natives.

Genus HEMIRAMPHUS, *Cuvier*, 1817. Upper jaw very short, formed by the intermaxillaries; symphysis of lower jaw extended into a long point, behind which on the margins of both jaws a narrow band of small teeth; scales large, rounded, forming a carinated range on each side of abdomen; body and fins resembling *Belone*.

(3815) *Hemiramphus russelli*, Cuv. and Val.

Syn. Russell, CLXXVII. Kuddera, B.
Hemiramphus brevirostris. Cuv. R. A. II. 286 (1). [Cuvier refers this species to Russell No. CLXXVII, and to Willughby: Append. Pl. VII. Fig. 4, two distinct species according to M. Valenciennes, who therefore has changed the specific denomination.]
Hemiramphus brevirostris, Swainson, II. 297.
Hemiramphus russelli, Cuv. and Val. XIX. 32.
Toda pendek [*Pendek*, short. The Malays thus denominate all the species of *Hemiramphus*, to distinguish them from those of *Belone (Toda.)*] of the Malays.

Head above and back bluish black; lighter, silvery on the sides above the lateral line; rest of the sides, abdomen and opercles silvery with steel-blue reflections; fins hyaline; marginal half of dorsal and caudal minutely dotted with black; sides of lower mandible black. Iris silvery, orbital margin bluish black. D 17, C 15¾, A 13, V 6, P 12, Br. XIII. Inhabits *Sea of Pinang, Malayan Peninsula*, Coromandel. Total length: 10 inch. The length of the head from the apex of the intermaxillaries is ⅙ of the total measured to the point of the lower, longer, caudal lobe. The length of the lower jaw, from the apex to the angle of the mouth, slightly exceeds the length of the head, varying in different individuals from ⅕ to ⅙ of the distance to the point of the lower caudal lobe. The horizontal diameter of the eye is ¼ of the length of the head; the distance across the forehead equals 1½ diameter. The depth at occiput slightly exceeds ½ of the length of the head, and is but ⅔ of the greatest vertical diameter of the body, in front of the ventrals. The length of the pectorals is ⅙ less than that of the head, which is exceeded by ¼ by that of the lower caudal lobe. The upper caudal lobe is ⅔ of the lower. The ventrals are placed opposite the posterior third of the distance between the apex of the intermaxillaries and the root of the caudal. At Pinang this species is numerous at all seasons, but larger individuals occur at irregular intervals. They appear at European tables under the appellation of "Guard-fish."

(3816) *Hemiramphus georgii*, Cuv. and Val.

Syn. Hemiramphus georgii, Cuv. and Val. XIX. 37, Pl. 555.
Toda pendek of the Malays.

Young. Head above light greenish grey, minutely dotted with black, particularly on the intermaxillaries and about the occiput; back and sides towards the lateral line pale greenish grey; the margins of the scales minutely dotted with black; along each side a shining silvery band, divided in the middle by the lateral line, and edged above by a deep blue line; abdomen faint silvery white; opercles shining silvery with steel-blue reflections; lower jaw greenish grey, with a black marginal membrane; dorsal and caudal pale greenish grey; marginal half dotted with black; rest of the fins hyaline. Iris silvery; orbital margin bluish black. D 15 or 16, C 15¾, A 15, V 6, P 12, Br. XII? Inhabits *Sea of Pinang*, Bombay, Mahe. The length of the head from the apex of the intermaxillaries is 5⅓ in the distance to the point of the lower caudal lobe. The length of the lower jaw from the apex to where the teeth of both sides meet, varies individually from 3⅔ to 3½ in the total length. The horizontal diameter of the eye is ¼ of the length of the head; the distance across the forehead exceeds by ¼ the diameter. The arch of the roof of the orbits makes the middle of the forehead appear excavated. The depth at occiput is ½ of the length of the head. The band of teeth of the intermaxillaries is very narrow at the angle of the mouth, gradually widening towards the apex. The inner series of these teeth are somewhat longer than the rest. The lower jaw has but a single series of minute teeth, behind which the anterior half of the mouth is lined by a crescent-shaped black membrane. The length of the pectorals is [illegible] of the head. The ventrals are placed in [illegible] the posterior third of the distance between the occiput and a short [illegible] of the caudal. The [illegible] diameter [illegible] of the ventrals is a little more than [illegible] of the head. The caudal is but slightly [illegible]; the lower lobe, but little longer than the upper, is ¾ of the length of the head. The two anterior dorsal rays are undivided. M. Valenciennes counts 17 rays in this fine, but his figure gives 16. Single young individuals occur at Pinang at all seasons.

(3817) *Hemiramphus tridentifer*, Cantor.

Syn. Toda pendek of the Malays.

Head above, back and upper part of the sides light bluish green, minutely dotted with black, particularly towards the margin of the scales; along each side a shining silvery band, widening between the dorsal and anal: narrower in front of the caudal; the band edged above by a deep blue line, and longitudinally divided by the lateral line; rest of the sides and abdomen pale silvery white; cheeks and opercles shining silvery, the latter and the root of the lower jaw with strong steel-blue reflections; point of lower jaw with greenish blue minutely dotted with black, with a black marginal membrane, apex red sealingwax colour; dorsal hyaline, margin of the rays minutely dotted with black; anterior half of caudal pale greenish buff, posterior half, upper and lower margin pale blackish, rest of the fins hyaline. Iris silvery, upper half of orbital margin bluish black. D 13 or 14, C 15¾ A 14 or 15, V 6, P 13, Br. XII or XIII. Inhabits *Sea of Pinang*. Total length: 7 inch. The

length of the head from the apex of the intermaxillaries is $5\frac{1}{2}$ in the distance to the point of the lower caudal lobe. The length of the lower jaw from the apex to where the teeth of both sides meet varies from $6\frac{1}{2}$ to $6\frac{2}{3}$ in the total length. Measured to the angle of the mouth, the lower jaw is from $5\frac{1}{5}$ to $5\frac{2}{3}$ in the total length. The horizontal diameter of the eye is $\frac{1}{4}$ of the length of the head; the distance across the flattened forehead equals the diameter. The depth at occiput equals $\frac{1}{2}$ of the length of the head. The teeth of both jaws are placed on narrow bands; in the centre of the lower jaw there is a very minute interval between the teeth of both branches. The teeth themselves are very minute, the internal series a little longer than the rest. Examined through a lens the apex of each tooth appears compressed, terminating in three minute points, of which the central one is a little longer than the two lateral. The intermaxillary forms a nearly equilateral triangle, each side of which is $\frac{2}{3}$ of the horizontal diameter of the eye; the band of teeth of the lower jaw is longer, arched or like a horse-shoe. The length of the pointed pectorals is $\frac{3}{4}$ of that of the head; the ventrals, slightly exceeding $\frac{1}{2}$ of the pectorals, are placed far forward: they commence in the middle of the distance between the anterior margin of the orbit and the root of the caudal. The vertical diameter in front of the ventrals is $6\frac{2}{3}$ in the distance between the gill-opening and the root of the caudal. The dorsal commences a little behind the posterior third of the distance between the occiput and the root of the caudal; the extent of the base is $\frac{3}{4}$ of the length of the head; the first and second ray undivided; the latter and the third are the longest, $\frac{5}{3}$ of the extent of the base. The last ray is a little elongated. The anal is placed opposite the dorsal, which it resembles in shape and extent. The caudal is but slightly cleft; the lower lobe equals the length of the head; the upper one about $\frac{1}{8}$ less. The scales are large, rounded; the vertical diameter of the part exposed is about the double of the horizontal. The abdominal crest is distinct. This species has several characters in common with *H. gernaerti*, Cuv. and Val., but it differs from that and from all the other species by its peculiar dentition. In *Exocoetus volitans*, Linn., the pharyngeal teeth before they become worn, are flattened and tricuspidate. Perhaps it may be inferred that the individuals of the present species are young, although the young of the preceding species have simple pointed teeth. They are numerous at all seasons at Pinang, and are eaten by the natives.

Genus EXOCOETUS, (*Artedi,*) *Linne* 1748. Pectorals excessively large; head and body scaly with a salient line on each side of the abdomen; head depressed; cheeks compressed; eyes large; intermaxillaries without pedicles, forming the edge of the upper jaw; dorsal placed opposite the anal; intermaxillaries with minute pointed teeth; pharyngeals with teeth as if paved.

(3818) *Exocoetus nigripennus*, Cuv. and Val.

Syn. Exocoetus nigripennis, Cuv. and Val. XIX. 108.

Head above, back and upper half of the sides ultramarine with purple gloss; lower half of the sides, abdomen, cheeks and opercles light silvery ultramarine, minutely dotted with black; dorsal, ventrals and pectorals black; pectoral rays silvery sky-blue; caudal yellowish white, at the root bluish dotted with black; anterior half of ventrals hyaline, posterior black, base blue. Iris silvery; orbital half bluish black. D 11, 12 or 13. C i $5\frac{3}{3}$, A 8, 9 or 10, V 6, P 15, Br. XI. Inhabits *Sea of Pinang*, China Sea. Total length: 3 inch. The length of the head is $5\frac{1}{3}$ in the total, measured to the point of the lower caudal lobe. The horizontal diameter of the eye is $\frac{1}{2}$ of the length of the head. The arch of the roof of the orbit makes the middle of the forehead appear excavated; the distance across the forehead between the posterior angles of the orbit slightly exceeds the diameter of the eye; between the anterior angles it is slightly less than the diameter. The depth at occiput, as well as the vertical diameter in front of the ventrals, is $\frac{3}{4}$ of the length of the head. The scales of the body are rather large, and so deciduous that few are in their places. The lateral line and the salient line on each side of abdomen can barely be traced. The teeth of both jaws are excessively minute and apparently confined to the central part. Each palatal has a single external series of minute teeth, and a few scattered over the surface, which appears like a fine file. The teeth are probably deciduous, and so minute that they cannot be seen in fresh specimens, and in dried ones only by means of a powerful lens. The pharyngeal teeth are tricuspid. The lower margin of the horizontal part of the preopercle is toothed. The length of the pectorals differs individually: they do not exceed $\frac{1}{2}$ of the head and body, (the caudal not included). The ventrals are $\frac{1}{3}$ of the total length; the lower caudal lobe is $4\frac{1}{2}$ in the total length, the upper one but slightly exceeds $\frac{1}{2}$ of the former. The intestinal canal is wide at œsophagus, gradually narrowing in its straight course towards the anus. Its length is scarcely $\frac{1}{2}$ of the total. The liver consists of a single small lobe. The white air-vessel is comparatively very large, thin, elongated, its length slightly exceeding $\frac{1}{2}$ of the total. The peritoneum is silvery, sparingly dotted with black. In the course of four years ten individuals were obtained at Pinang. They occurred singly and at irregular intervals, and varied from two to three inches in length.

Genus PANCHAX, *Valenciennes* 1846. [In 1836, Mr. McClelland placed some species of this genus in the family of Cyprinoidœ, and

formed a Subgenus of Poecilia, Bl. Schn. to receive them, viz. Aplocheilus, Ser. (Haplocheilus)—Mr. McClelland characterises the latter as follows: "Intermaxillaries fixed, apices of the jaws flat and directed upwards; five rays in the branchial membrane; fins transparent; a short dorsal placed opposite to the last ray of a long anal; the intestine and stomach form together a small tube scarcely longer than the body; the eyes placed on the edges of the head; the mouth directed upwards; a single row of large teeth inserted along the edges of the lips which are not protractile as in Poecilia: the caudal entire." (Asiatic Researches. XIX. Pt. II. pp 301 and 426). Of the preceding eleven characters only four are correct, but they are not sufficient to chracterise the genus, viz.: apices of the jaws flat; intestinal canal scarcely longer than the body; eyes on the edges of the head; caudal entire. The remaining characters are either partly incorrect or entirely so. The characters of Panchax, Valenciennes, although of a later date than Haplochilus, must therefore be adopted.] Maxillary bone thrown behind the descending branch of the inter maxillary, so that but the lower part contributes to form the angle of the mouth; muzzle broad depressed; gill-openings well cleft; dorsal small, placed far back opposite the anal; intermaxillaries and lower jaw with a narrow band of minute teeth of which the external series are longer than the rest and arched round the margin of the jaws, so as to appear like cilia; a narrow transversal band of minute teeth on the palate (vomer).

(3819) *Panchax panchax*, (Buchan. Ham.)

Syn. Esox panchax, Buchan. Ham. 211, 380, Pl. III. Fig. 69.
Apolcheilus chrysostigmus, McClelland, As. Res. XIX. II. 301, and 426, Pl. XLII. Fig. 2.
Aplocheilus panchax, McClelland ibid. 302.
Panchax buchanani, Cuv. and Val. XVIII. 383.

Head above, back and upper half of the sides pale silvery green, minutely dotted with black; lower half of the sides and the abdomen silvery white, in some individuals with orange coloured dots; on the occiput a small oval silvery white spot; sides of the head and upper half of opercles silvery green minutely dotted with black, lower half white; lower jaw and the throat immediately behind minutely dotted with black, so as to appear like two narrow arched black lines; rest of the throat yellow or white; dorsal hyaline or orange with a large rounded black spot occupying the basal half; in some individuals a small white spot in front of the dorsal, in others the upper margin black; caudal greenish grey minutely dotted with black, upper and lower margin orange edged with black anal hyaline edged and spotted with orange; ventrals and pectorals yellow. Iris reddish silvery with a blackish ring. D 9, C 15$\frac{1}{5}$, A 17, V 6, P 15, Pr. VI. Inhabits *Fresh water Pinang*, Bengal. Total length: 2$\frac{1}{2}$ inch. The length of the head is $\frac{1}{4}$ of the total; the depth at occiput is $\frac{1}{2}$ of the length of the head. The horizontal diameter of the eye is a little less than $\frac{1}{4}$ of the head; the distance across the forehead equals two diameters. The nostrils open laterally by two minute apertures placed above each other in front of the anterior orbital margin. There are no lips. The intermaxillaries are very protractile, and are slightly moveable up and down like a lid. Both the external and the internal series of the teeth of the jaws, are a little longer and more distant than the rest of the teeth. Behind the intermaxillaries appears a small crescent-shaped membrane. Behind the latter are some excessively minute teeth placed on a narrow band, which crosses the vomer and forms an arch parallel with the intermaxillary teeth. The tongue is small, fleshy, and as well as the cavity of the mouth dotted with black. The body is covered by 7 longitudinal series of proportionally large scales, with concentric lines and about 13 radical rays. There are about 30 scales in a series between the gill-opening and the caudal. No lateral line is visible, but on each of the anterior 6 to 8 scales of the third series, appears a central impression as if pricked with a needle. The dorsal commences opposite the posterior third of the anal. The ventrals have no filament. It is numerous at Pinang in ponds, paddy fields and ditches. The stomach and intestines form a continued tube, in length scarcely $\frac{1}{2}$ of the total. The peritoneum is silvery, dotted with black. The number of fin rays given by Buchanan and Mr. McClelland are incorrect.

ORDER PHYSOSTOMI. SUBORDER PHYSOSTOMI ABDOMINALES.

Fam. SILUROIDÆ.

Genus BAGRUS, (*Rafinesque,*) *Cuvier*, 1817. A band of velvety, or card-like teeth in both jaws; on the vomer a second, posterior band, either velvety or in a single series.

(3820) *Bagrus abbreviatus*, Cuv. and Val.

Syn. Bagrus abbreviatus, Cuv. and Val. XIV. 420.
Pimelodus abbreviatus, Kuhl and Van Hasselt, ibid.
Bagrus abbreviatus, Bleeker: Verhand. Batav. Genoots. XXI. 4.

Head above and back dark greenish olive, lighter silvery on the sides; abdomen silvery white; fins greenish grey; their membranes whitish at the base, the rest minutely dotted with black; adipose fin greenish olive minutely dotted with black; nasal cirri grey; maxillary black; both mandibular pairs white, Iris greenish

golden, blackish towards the orbit. D 1/7—1 (adipose), C $17\frac{4}{7}$, A 13, V 6, P 1/8 or 9, Br. IX.

Cirri: $\frac{4}{4}$

Inhabits *Sea and estuaries of Pinang*, Java. Total length 1 foot 6 inch. The length of the head is $4\frac{1}{2}$ in the total; the horizontal diameter of the orbit is $\frac{1}{5}$ of the length of the head; the distance of the eyes across the head two such diameters. The long helmet is finely shagreened to between the eyes, where its breadth is $\frac{1}{2}$ of its length; the occipital point is narrow triangular, occupying half the interval between the occiput and the dorsal spine, and receiving in a notch the point of the second interspinal. The mastoid and suprascapular processes form an elongated arch surrounding the opercle and nearly touching the humeral. The latter is elongated triangular, its length twice its height. The opercle is finely shagreened like the rest of the bones forming the helmet, and has besides some radiating lines. The greatest breadth of the head nearly equals its length, and also the greatest vertical diameter of the body, in front of the dorsal spine. The card-like teeth are disposed on narrow bands in the jaws and on the vomer. The nasal cirri extend to the preopercle, the maxillary to the point of the ventrals, the external mandibular to the point of the pectorals; the internal are one half of the external. The dorsal spine is rather slender, longitudinally striated, with teeth on the posterior margin, and two or three on the anterior near the apex. The length is $\frac{1}{4}$ of the first dorsal ray, which is $\frac{3}{4}$ of the length of the head. The adipose dorsal is as high as the anal, but of half the extent. Each lobe of the furcated caudal equals the head; in young individuals the upper one terminates in a short filament. The pectoral spine is longer and broader than the dorsal; the upper surface is lineated, the margin towards the rays is strongly toothed. At Pinang individuals occur at all seasons, but not in great numbers. They are eaten by the natives.

(3821) *Bagrus sondaicus*, Cuv. and Val.

Syn. Bagrus sondaicus, Cuv. and Val. XIV. 444.
Bagrus sondaicus, Bleeker: Verhandel. Batav. Genoots. XXI. 4, 14, 29 and XXII. 5.

Helmet dark olive bronze, (tubercles white,) lighter on the cheeks and opercles; back deep steel-blue with greenish reflections, the sides, to a little beneath the lateral line, lighter, silvery, with from 12 to 15 vertical bands reflecting steel grey or pale golden green; rest of the sides and abdomen silvery white; fins greenish grey minutely dotted with black; external half of pectorals, anal and the lower caudal lobe blackish; maxillary cirri black; external mandibular white at the base, rest black; internal maxillary white. Iris golden green, blackish towards the orbit. D 1/7—1 (adipose), C $15\frac{1}{7}$. A 17 or 18, V 6, P 1/10, Br. VI.

Cirri: $\frac{2}{6}$

Inhabits *Sea of Pinang, Malayan Peninsula*, Straits of Sunda, Java, Madura. Total length: 1 foot 9 inch. The length of the head is $\frac{1}{5}$ of the total, slightly exceeding the greatest vertical diameter of the body, in front of the dorsal spine. The breadth of the head nearly equals the length. The horizontal diameter of the orbit is $6\frac{1}{2}$ in the length in the head. The bones forming the helmet are granulated as far as the anterior margin of the orbit, but the small triangular truncated suprascapular is like the opercle smooth but radiated. The sides of interspinal form an angle with the centre part, and terminate behind in a blunt point. The interparietal is broad truncated or rounded behind; its length is $\frac{1}{4}$ of the rest of the helmet, its breadth about $\frac{1}{2}$. The humeral is pointed, granulated, triangular, its length $2\frac{1}{2}$ in the head. The teeth are strong, card-like. Those on the vomer are placed on two small oval spots; those on the palate on two similar but larger, all four forming one series, broader than the maxillary ones. The palatal teeth easily fall out, which renders the fish liable to be mistaken for a species of *Arius*. The maxillary cirri reach to the point of the pectorals; the external mandibular to the base of the pectorals; the internal are $\frac{1}{3}$ of the external. The dorsal spine is $\frac{1}{5}$ of the head, granulated on the anterior half of its sides; near the apex the anterior margin carries 4 or 5 small teeth, the posterior 6 or 7 similar ones. The point terminates in a short soft filament, which is easily torn off. The pectoral spine equals the length of the head; the anterior half of the external margin is granulated; the corresponding parts of the sides is lineated; the external margin carries near the point a few weak teeth, and similar appear along the internal margin. The point terminates in a soft filament, longer than that of the dorsal. The upper caudal lobe, a little longer than the lower, is $4\frac{2}{5}$ in the total length. The ventrals are $\frac{1}{2}$ of the pectorals. The extent of the adipose dorsal is $\frac{1}{3}$ of the anal. At the origin of the lateral line appear some minute elongated grains; the line itself consists of small tubes which become indistinct after it has passed the dorsal fin. This species is more or less numerous at all seasons. It is eaten by the natives and the air-vessels collected for the China market. M. Bleeker thinks it probable that *B. javensis*, Cuv. and Val. (XIV. 445) is identical with *B. sondaicus*. [Bleeker l. c., 4 (1)].

Genus ARIUS, *Cuv. and Val.* 1840. Palatal teeth on two distinct separate plates, in some species advancing on the lateral angles of vomer.

(3822) *Arius truncatus*, Cuv. and Val.

Syn. Arius truncatus, Cuv. and Val. XV. 64.
Arius truncatus, Bleeker Ver. Bat. Gen. 4.

Head above and back intense blue with silvery reflections, cheeks and opercles golden bronze: throat and sides golden; abdomen silvery white, sparingly dotted with black; fins greyish white minutely dotted with black; margins of dorsal and caudal black: in the adult the posterior half of the caudal and the anal pale lake; adipose pale greyish olive minutely dotted with brown; maxillary cirri black; mandibular pairs white. Iris golden dotted with black. D 1/7—1 (adipose), C $15\frac{1}{11}$, A 23 or 24, V 6, P 1/9, Br. VI.

Cirri: $\frac{2}{4}$

Inhabits *Sea and estuaries of Pinang, Malayan Peninsula,* Java. Total length: $11\frac{2}{8}$ inch. The length of the head measured to the point of the opercle is a little less than $\frac{1}{4}$ of the total, but to the posterior margin of the first interspinal it is $\frac{1}{5}$ of the total. The latter bone is narrow rectangular, its breadth being $1\frac{2}{3}$ in the length which is $\frac{1}{6}$ of the distance to the muzzle. The helmet is granulated and partially striated, its anterior two thirds divided by a longitudinal furrow commencing on the forehead on a level with the nostrils. The cheeks and opercles are veined, and the latter also indistinctly radiated. The anterior half of the head is much depressed, the muzzle rounded, truncated. The teeth of both jaws are on narrow bands, card-like and finer than the palatals, which are crowded on a small oval spot on each side. The cirri are slender: the maxillary ones reach to about the middle of the opercle; the mandibular pairs are nearly equal, $\frac{3}{4}$ of the former. The eyes are situated at the anterior third of the head, their horizontal diameter is in the young $\frac{1}{7}$ in the older $\frac{1}{8}$ of the length of the head; their distance across the forehead is about 4 such diameters. The vertical diameter at occiput is $\frac{1}{2}$ of the length of the head; that in front of the dorsal is a little less than $\frac{2}{3}$ of the head. The dorsal spine is strong, $\frac{3}{4}$ of the length of the head, equalling in length the first ray. The posterior margin and that part of the anterior nearest the apex are finely toothed, the rest is granulated. The pectoral spine is but $\frac{2}{3}$ of the dorsal which it otherwise resembles, but the teeth of the posterior margin are stronger. The pectorals and ventrals are nearly of equal length or about $\frac{1}{2}$ of the length of the head. The extent of the anal equals the greatest vertical diameter of the body; the length of the eighth and ninth rays is a little less than that of the ventrals. The extent of the adipose dorsal is $\frac{1}{3}$ of the anal, its height $\frac{1}{2}$ of the longest rays of the latter. The caudal is deeply cleft, the lobes equal, and their length, normally, like the dorsal spine. The lateral line follows the outline of the back at the upper third of the body; arrived at the base of the caudal it continues a short distance obliquely downwards over the three upper rays of the lower lobe. The line consist of little separated tubes, each with a minute downwards pointed process at the posterior part. The two superior branchiostegous rays on each side are very broad and exposed, so as to appear like a subopercle. The stomach is capacious, thin, containing remains of *Crustacea* and mud. The intestinal canal slightly exceeds double the total length. The air-vessel is small but very thick transversely divided in two compartments. The fish is held in esteem by the natives, but at Pinang it is of so rare occurrence that the air-vessel contributes but little to the general stock of Isinglass obtained from other species.

(3823) *Arius arius*, (Buchanan Hamilton.)

Syn. Pimelodus arius, Buchan. Ham. 170, 376.
Arius arius, Cuv. and Val. XV. 102.
Ikan Saludu or Surdudu.

Adult. Head above and back intense steel blue; cheeks, opercles and sides greenish golden or bronze; throat and abdomen white slightly dotted with black; dorsal greyish white minutely dotted with black; filament of the spine and the upper margin black; caudal yellowish white minutely dotted with brown; anal and pectorals white, external half so closely dotted with black as to assume that colour; ventrals hyaline, closely dotted with brown; adipose pale greyish olive with a large black spot, posterior margin white; maxillary cirri blackish; mandibular pairs white. Iris greenish golden, orbital margin blackish. *Young.* Dorsal, posterior half of caudal, middle of anal and base of adipose pale lake. D 1/7—1 (adipose), C $15\frac{5}{8}$, A 18 to 21, V 5, P 1/10, Br. V.

Cirri: $\frac{2}{4}$

Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore,* Pondicherry, Gangetic estuaries. Total length: 1 foot 10 inch. The length of the head is $\frac{1}{4}$ of the total. The helmet is granulated to the middle above the orbit. The first interspinal is rectangular nearly square, its length $\frac{1}{6}$ of the distance to the muzzle; the posterior margin is notched, receiving a broad point from the crescent-shaped second interspinal. The anterior two thirds of the helmet are divided by a broad longitudinal furrow. The interopercle and opercle are radiated, the point of the latter indistinctly granular. The horizontal diameter of the orbit is $\frac{1}{4}$ of the length of the head. The teeth of the jaws are card-like, on narrow bands. Those of the palate are granular, placed on two close oval spots. The maxillary cirri do not quite reach to the apex of the pectoral spine; the external mandibular pairs is $\frac{1}{5}$ shorter; the internal is $\frac{1}{2}$ of the external. The vertical diameter in front of the dorsal slightly exceeds the length of the head, and equals the length of the dorsal spine. The latter is very strong, the posterior margin of the anterior near the apex are toothed, the rest is coarsely granulated. To the apex is attached a soft filament,

seldom exceeding $\frac{1}{5}$ the length of the spine. The pectoral spine resembles the former, but it is slenderer, shorter by $\frac{1}{4}$, and without filament. The extent of the adipose is $\frac{1}{3}$ of that of the anal; its height $\frac{1}{3}$ of the length of the sixth and seventh rays, which is $\frac{1}{4}$ of the head. The caudal lobes equal the length of the head. The lateral line resembles that of *Arius truncatus*, but it keeps nearer to the middle of the body. At Pinang smaller individuals of this species are very numerous at all seasons. They form an article of food, and contribute more than any other of the *Siluroidæ* to the exportation of isinglass.

(3824) *Arius militaris*, (Linne.)?

Syn. Silurus militaris Linne: Syst. 1356.?
Arius militaris Cuv. and Val. XV. 114. Pl. 430.
Osteogeneiosus Bleeker: Verhandel. Batav. Genootsch. XXI. 49. [Osteogeneiosus, *Bleeker*, 1847, (Scrib. Osteogenenius.) Teeth on the anterior part of the palate disposed in two oblong arched group; two supra-maxillary bony, rigid cirri; branchiostegous rays five. Otherwise resembling *Arius*.]

Head above and back bottle-green bronze, lighter on the sides of the head and body: abdomen silvery white, anterior half minutely dotted with brown; dorsal and caudal pale greyish olive, minutely dotted with black, margin blackish; rest of the fins white; upper half between anterior four rays of ventrals dotted with black; upper surface of pectorals and posterior half of lower black, in the axilla a black spot along the root of pectorals; jaws and root of the long cirrus-like maxillary prolongation blackish bronze, rest of the latter reddish white; adipose fin greenish olive dotted with black, posterior margin white. Iris greenish golden dotted with black. D 1/7—1 (adipose), C 15$\frac{2}{3}$, A 21, V 6, P 1/10, Br. V.

$$\text{Cirri} \begin{matrix} 2 \\ — \\ 0 \end{matrix}$$

Inhabits *Sea and estuaries of Malayan Peninsula and Islands*, Sea and estuaries of Malabar, Coromandel; estuaries of Ganges and Irawaddy. Total length: 1 foot 6 inch. The length of the head is 4$\frac{1}{2}$ in the total. It is completely covered by smooth skin, and but a few granulations appear on the anterior part of the elliptic interparietal. The rest of the bone, like the opercles, is radiated; it occupies $\frac{1}{4}$ of the distance from the muzzle. The horizontal diameter of the eye is $\frac{1}{6}$ of the length of the head; the distance across the forehead is about three such diameters. The card-like teeth of the jaws are on broad bands; that of the upper one is the shorter, as it does not reach to the angle of the mouth, but terminates at the root of the bony cirrus-like elongation of the upper maxillary bone. The latter is slender, elastic, flattened with a shallow furrow on each side; its length equals the head; the anterior sixth is attached to the side of the head by a small triangular membrane which is, however, too short to admit of the bone being projected at a right angle. The palatal teeth are granular, placed in two separated groups of an irregular rhomboidal shape. The vertical diameter of the body, in front of the dorsal, is $\frac{3}{4}$ of the length of the head. The dorsal spine is slender, the lower half of the anterior margin is finely granulated, the upper half and the posterior margin are very finely toothed; it is a little shorter than the first ray which is $\frac{2}{3}$ of the length of the head. The pectoral spine resembles the dorsal and is but a little shorter. The extent of the anal is $\frac{1}{6}$ of the length of the body; the eighth, the longest ray, slightly exceeding $\frac{1}{2}$ of the extent. The extent of the adipose fin is about $\frac{1}{3}$ of the anal, but of nearly equal height. The caudal is slightly cleft, and the lobes a little round; their length is $\frac{1}{7}$ of the total. The lateral line resembles that of *Arius truncatus*. At Pinang single individuals occur at all seasons; they are eaten by the natives, and their air-vessels preserved.

Genus PIMELODUS, (*Lacepede*, 1808,) *Cuv. and Val.* 1840. Palate smooth, without teeth; six or eight cirri; with or without helmet.

(3825) *Pimelodus pectinidens*, Cantor.

Young? Head above and back yellowish green bronze, dotted with black; between the anterior points of the helmet an oval yellowish white spot, cheeks, opercles and sides of the body silvery; the two first minutely dotted with black; throat and abdomen white; fins, including the adipose, yellowish white; maxillary cirri black; mandibular pairs white. Iris golden minutely dotted with black. D 1/7—1 (adipose), C 15$\frac{2}{3}$, A 20, V 6, P 1/8, Br. IV.

$$\text{Cirri} \begin{matrix} 2 \\ — \\ 4 \end{matrix}$$

Inhabits *Fresh-water, Pinang*. Total length: 4$\frac{2}{3}$ inch. The greatest vertical diameter of the body, in front of the dorsal fin, is $\frac{1}{5}$ of the total length; from thence the profile descends in a nearly straight line to the rounded muzzle. To the point of the opercle the length of the head is $\frac{1}{5}$ of the total, but to the point of the interparietal bone is 3$\frac{3}{4}$. Above the head is depressed, transversely arched, its greatest breadth at the occiput is $\frac{1}{5}$ less than its length. The interparietal is triangular truncated, its length $\frac{1}{3}$ of the distance to the muzzle, its breadth at the base equal its length; the truncated apex is notched, receiving the point of the second interspinal. The whole of the helmet is finely granulated to above the posterior margin of the orbit. It is longitudinally divided by a furrow terminating a little behind the anterior half of the distance between

the muzzle and the dorsal. The suprascapular bone is narrow, pointed, and joins the equilateral triangular humeral. Both as well as the opercles are rough and striated. The sides of the opercle equals that of the preopercle and interopercle together. The cheeks are smooth. The mouth is large, the angle reaching to the posterior margin of the orbit; the fleshy lips completely hide the teeth; the upper jaw projects beyond the lower. In each jaw appears a single series of closely set, small, flattened teeth, resembling a fine comb. To the naked eye the apex of the teeth appears to be truncated, trenchant, but under a lens it is bluntly trilobate. The cirri are very fine: the maxillary reach to the preopercle, the mandibular pairs are so short as to easily escape observation. The nostrils open closely in front of the orbit. The latter occupies the second fourth of the head, a little nearer to the jaw than to the forehead; the greatest diameter, obliquely downwards, is a little less than $\frac{1}{4}$ of the length of the head. Of the four branchiostegous rays, the two upper ones are longer and broader than the lower. The dorsal spine is strong and nearly as long as the head, the two sides are striated, the lower half of the anterior margin is granulated, the upper half of this and of the posterior margin is finely toothed; the first ray is a little longer than the spine. The pectoral spine is a little shorter than the dorsal, which it otherwise resembles. The ventrals are $\frac{2}{3}$ of the length of the head. The extent of the base of the anal is $\frac{3}{4}$, the eighth ray $\frac{2}{3}$ of the length of the head. The adipose dorsal fin is placed opposite the middle of the anal; its base and length are $\frac{1}{2}$ of the latter. The posterior margin of the caudal is nearly crescent-shaped; the upper lobe slightly longer than the lower, is $4\frac{1}{2}$ in the total length. The lateral line resembles that of *Arius truncatus*. A single individual was observed at Pinang in August 1844. The yellowish white oval spot on the forehead is in some other *Siluroidæ* characteristic of immaturity. It may perhaps also be so in this species, notwithstanding the worn appearance of the trilobate teeth.

Genus CLARIAS, (*Gronov.* 1763,) *Valenciennes*, 1840. (Cossyphus, *McClelland*, 1843. Phagorus, *McClelland*, 1844.) [Sir John Richardson in this Report, 1845, p. 227, observes, that "*Cossyphus ater*, McClelland, (Calcutta Journ. IV. p. 403, Pl. 22, Fig. 3.) is apparently an injured example of this genus," (*Plotosus*, apud Richardson.) *Cossyphus ater*, McClelland, is founded upon a *mutilated specimen* of either *Clarias jagur*, (*Macropteronotus jagur*, Buch. Hamilton, 145, 374.) or upon a closely allied species, but more probably upon the former. Mr. McClelland later substituted *Phagorus* for *Cossyphus* (Calcutta Journ V. 225, *Errata.*)] Head with a long, granular helmit, formed by the cranial and suprascapular bones; the interparietal advancing on the occiput as a more or less soft lamina, supported by the occipital crest; card-like or granular teeth on the vomer; dorsal without spine; occupying nearly the whole of the back; anal less extensive; margin of pectoral spine minutely toothed; on each side two ramified branchial appendages; branchiostegous rays 9 to 11.

(3826) *Clarias Punctatus*, Cuv. and Val.

Syn. Clarias punctatus, Cuv. and Val. XV. 384.

Clarias punctatus, Bleeker: Verhandel. Bat. Genoot. XXI. 4, 17, 53.

Head, body, fins, and cirri blackish brown; with purple or lilac reflections; body either uniformly so or with large irregular lighter spots, with eight to ten vertical series, each consisting of four to six whitish dots, in number and distribution liable to individual variations; pectoral spine, throat, and abdomen as far as the ventrals, brownish white. Iris dark brown. D 70, C $17\frac{4}{4}$, A 51 to 53, V 6, P 1/8, Br. IX. $\frac{4}{4}$ Cirri— $\frac{4}{4}$

Inhabits *Estuaries and freshwater*, *Pinang*, Java. Total length: 10 inch. Measured to the apex of the interparietal, the head slightly exceeds $\frac{1}{6}$ of the total length, (to the point of the opercle it is $\frac{1}{8}$); the breadth between the gill-openings is $\frac{3}{4}$ of the length. The eye is situated at the anterior fourth, its horizontal diameter is $\frac{1}{9}$, and the distance across the forehead is $2\frac{1}{2}$ in the length of the head to the apex of the interparietal. The latter is triangular with the apex rounded, the base double the length, which is $\frac{1}{8}$ of the distance to the muzzle. In the centre of the helmet appear two ovoid apertures, covered by the integuments: the anterior is $\frac{1}{5}$, the posterior $\frac{1}{10}$ of the length of the head. The maxillary cirri slightly exceed $\frac{1}{4}$ of the total length, nearly reaching to the apex of the pectoral spine; the nasal are $\frac{1}{6}$, the outer mandibular $\frac{1}{5}$, and the inner mandibular $\frac{1}{8}$ of the total length. The teeth are card-like: those of the upper jaw on a broad band, reaching to the root of the maxillary cirri; those of the vomer and palate forming a narrow crescent. The dorsal fin commences at a distance from the apex of the interparietal, equalling $\frac{1}{7}$ of the length of the head. The pectoral spine is strong, like a sabre: the surfaces finely striated, the outer margin finely granulated with two or three teeth near the apex, the inner finely toothed; the length of the spine is $7\frac{1}{2}$ in the total; the first rays are a little longer. The ventrals are situated at the anterior third of the total length, in which they are contained $10\frac{1}{2}$ times. Between the anus and the anal fin appears a short conical appendage. The length of the caudal is $7\frac{1}{2}$ in the total. The stomach is a short rounded sac, the intestinal caudal is about

$\frac{1}{2}$ of the total length; the liver is divided in two short lobes; the left is again subdivided in two; the gall is oval, large; the spleen is small, flattened, oval. The posterior branchial appendage is large, nearly double the size of the anterior. This species is numerous at all seasons. It is eaten by the poorer classes of natives.

Genus PLOTOSUS, *Lacepede*, 1803. Body; elongated, terminating in a compressed point two dorsals, of which the second, caudal and anal united; head naked: strong conical teeth in the jaws and vomer; eight short cirri; behind the conical anal papilla a small ramified appendage.

(3827) *Plotosus Anguillaris*, (Bloch.)

Plotosus lineatus, Temm. et Schl. Fauna Jap. Pisc. 228. Pl. CIV. Fig. 3.
Plotosus lineatus, Blecker: Verh. Bat. Gen. XXI. 4, 17. 57.
Similang karong of the Malays.

Young. Head above and back blackish olive, lighter or copper coloured on the sides of the head and body; two white bands along the body: one from the muzzle above the eye along the back, a second, broader, from the maxillary cirrus, and in some a third from the ventrals; lips, throat and abdomen white; fins pale brownish olive or lake, dotted and edged with black; upper part of first dorsal with a black spot; anal papilla and ramified appendage crimson; nasal and maxillary cirri blackish; mandibular pairs white. Iris golden dotted with black. *Adult*. The lateral white bands indistinct. 1st D 1/4.—2d D, C and A 172 or 172, V 13 or 14, P 1/11, Br. XI or XII.—Cirri $\frac{1}{4}$. Inhabits *Sea and estuaries of Malayan Peninsula and Islands*, Isle of France, Society-and Friendly Islands, Japan, Philippines, China Seas, Amboina, Celebes, Java, Seychelles, Red Sea, Malabar, Ceylon, Coromandel, Western Australia. Total length: 10 inch. The length of the head is $5\frac{1}{2}$ in the total, its depth at occiput $\frac{1}{3}$ of the length. The horizontal diameter of the eye is $\frac{1}{6}$ of the length of the head; the distance across the forehead 2 such diameters. The greatest vertical diameter of the body, in front of the first dorsal, is $\frac{1}{6}$ of the total length. The maxillary and external mandibular cirri are equal, both pairs less than $\frac{1}{2}$ of the length of the head. The nasal and internal mandibular pairs are shorter. This species is very numerous at all seasons. In the stomach of those dissected was found *Modiola faba*, Benson, a very small bivalve inhabiting the Malayan estuaries.

(3828) *Plotosus albilabris*, Cuv. and Val.

Syn. Plotosus albilabris, Cuv. and Val. XV. 427.
Plotosus albilabris, Bleeker: Verh. Bat. Gen. XXI. 4.
Similang of the Malays.

Young. Head above and back blackish olive, lighter on the sides of the head (cheeks pale bluish), and of the body above the lateral line; beneath the latter, the throat and abdomen impure bluish white; lips pale blackish; body everywhere closely dotted with brown; pectorals blackish above, whitish beneath; rest of the fins pale greyish olive minutely dotted and edged with black; cirri blackish, root of mandibular pairs whitish; anal papilla and ramified appendage crimson. Iris golden dotted with brown. 1st D 1/4, V 13, P 1/9. Br, XII.—Cirri $\frac{1}{4}$ MM. Cuvier and Valenciennes count: 2d D 109, C 11, A 97, (total: 217). Inhabits *Sea and estuaries of Pinang, Malayan Peninsula*, Batavia. Total length: $6\frac{1}{8}$ inch. The length of the head is $\frac{1}{6}$ of the total; the depth at occiput little more than $\frac{1}{2}$ of the head. The horizontal diameter of the eye is $\frac{1}{6}$ of the head, the distance across the forehead two such diameters. The nasal cirri are a little longer than the head, the maxillary a little shorter and slenderer, the outer mandibular are $\frac{2}{3}$ of the latter, the inner pair slightly shorter. M.M. Cuvier and Valenciennes describe the maxillary cirri as $\frac{1}{3}$ shorter than the nasal, but the outer mandibular pair as long as the latter. All the teeth are strong, conical. The greatest vertical diameter in front of the first dorsal is $\frac{1}{7}$ of the total length. The dorsal spine is $\frac{1}{2}$ of the length of the head and but little shorter than the first ray. The pectoral spine is slenderer than the dorsal, the first ray slightly exceeds $\frac{1}{2}$ of the length of the head. The ventrals are $\frac{1}{3}$ shorter than the pectoral. The caudal is oval, rounded. The lips are fleshy and papillular. Minute papillæ appear here and there on the body. The conical anal papilla is rather large,

and the ramified appendage longer and with a greater number of branches than in *P. anguillaris*. At Pinang, the present species is less numerous than the former. The wounds of both are equally dreaded, and both are eaten by the poorer classes of natives.

Fam. CYPRINOIDÆ.

Genus CAPOETA, *Cuv. and Val.* 1842. Third bony dorsal ray toothed; a filament at the angle of the mouth; body compressed, covered with large scales.

(3829) *Capoeta macrolepidota*, Kuhl and Van Hasselt.

Syn. Capoeta macrolepidota, Cuv. and Val. XVI. 280, Pl 477, (*Young.*)

Adult. Head above brownish olive; back silvery greenish olive, lighter on the upper half of the sides, the rest and abdomen light golden; all the scales edged with pale brown, some with a pale dark spot at the root; the oblique series in front of the dorsal fin greenish olive, forming a dark obliquely backwards-directed band, interrupted by the lateral line; opercles and cheeks shining iridescent silvery; between the eye and the angle of the mouth a blackish blue triangular spot terminating in lines radiating towards the preopercle; lips and cirri minutely dotted with black; fin-membranes transparent; rays buff, minutely dotted with black: the three first dorsal, and the first pectoral blackish; caudal with a broad blackish brim above and below. Iris golden, upper orbital half black. *Young.* Differs from the adult in having the dark oblique band in front of the dorsal more distinct and reaching to the abdomen; cheeks uniformly silvery without any spot. D 3/8, C 19 5/5, A 2/5 or 6, V 2/8, P 16, Br. III. Inhabits *Freshwater*, *Pinang*, Java, Tenasserim. Total length: 11 inch. The length of the head is 4 1/6 in the total: the depth at occiput 2/3 of the length of the head. The eye, bordering on the profile, occupies the second fourth of the head, that being the length of its horizontal diameter; the distance across the forehead is 1 1/3 diameter. The opercles and cheeks are naked. Four large infraorbitals surround the orbit. From the temple round the lower margin of the orbit over the infraorbital proceeds a tube, which sends downwards several shorter ones. The openings of the nostrils are situated close in front of the eye: both are separated by a projecting fleshy septum. The lips and tongue are fleshy; on the symphysis of the lower jaw appears a small protuberance. Behind both jaws appears a crescent-shaped fold of the membrane lining the mouth. The small filament at the angle of the mouth is 2/3 of the horizontal diameter of the eye. The greatest vertical diameter of the body, in front of the dorsal, is 4 1/2 in the total length. The sides are covered by 7 longitudinal series of large rhombic scales, of which there are 27 or 28 on the lateral line. The latter consists of a simple tube on each scale, of which the anterior five of the series deviate obliquely downwards, the rest (on the third series from below,) proceed straight to the caudal. All the scales have from 4 to 10 backwards radiating lines. The first dorsal ray is excessively short; the third, the longest, is 3/4 of the length of the head and has a few minute teeth in the middle of the posterior margin; the caudal lobes equal the length of the head; the length of the anal and ventrals is 1/2 of the latter; the first ventral ray is short and very slender; the length of the first pectoral ray, which has a few teeth on the outer margin near the root, equals that of the first dorsal. The latter is represented a little too short in the otherwise correct figure of M.M. Cuvier and Valenciennes. At Pinang the fish is not numerous. It is of good flavour. It rises to insects, remains of which were found in the stomach. The length of the intestinal canal exceeds by 1/2 the total; the stomach as well as the intestines are very thin. The air-vessel is very large, thin, white, consisting of two elongated oval portions, of which the anterior is truncated in front.

Genus LEUCISCUS, *Rondelet*, 1554. Sub Genus LEUCISCUS, *Valenciennes*, 1844. Neither spines nor cirri; dorsal and anal fins short.

(3830) *Leuciscus rasbora*, (Buchan. Ham.)

Syn. Cyprinus rasbora, Buchan. Ham. 329, 391, Pl. II. Fig. 90.
Leuciscus rasbora, Cuv. R. A. II. 276 (2).
Leuciscus rasbora, McClelland: As. Res. XIX. 292 and 407.
Cyprinus (Leuciscus) rasbora, Cuv. and Val. XVI. 438.

Head above, back and upper part of the sides yellowish green, the root and edges of the scales minutely dotted with black; along the middle of the side a longitudinal golden stripe, bordered beneath by an indistinct bluish black one; lower half of the side and abdomen silvery pale yellow; cheeks and opercles shining silvery, the latter with blue reflections dotted with black; caudal pale yellowish dotted with black, posterior margin blackish; rest of the fins whitish transparent. Iris silvery, orbital margin bluish dotted with black. D 9, C 19 4/5, A 8, V 9 or 10, P 13, Br. III. Inhabits *Freshwater*, *Pinang*, Freshwater, Bengal, Upper Assam. Total length: 4 1/2 inch. The length of the head is 4 1/2 in the total. The eye is situated a little in front of the second third of the head, bordering on the profile, its horizontal diameter is 3 1/3 in the length of the head, the distance across the forehead is 1 1/4 diameter. The cavity of the mouth is minutely dotted with black. As observed by Buchanan, the lower jaw terminates in a point, surmounted by a small tubercle which fits into a corresponding notch of the upper jaw. But of a number

examined at Pinang none presented three prehensile knobs on the lower jaw, as described by Mr. McClelland in a specimen collected in Upper Assam by the late Mr. Griffith. The greatest vertical diameter of the body, in front of the dorsal, slightly exceeds the length of the head. The sides are covered by 7 longitudinal series of large rounded scales, each with a number of lines radiating from the root. A straight line from the gill-opening to the caudal contains 23. The lateral line proceeds obliquely downwards to near the termination of the pectoral fin, from whence it continues on the sixth, the penultimate series of scales, straight to the caudal. The first dorsal ray is situated a little behind the second half of the distance between the muzzle and the caudal, opposite the posterior ventral ray. The second dorsal ray, the longest, nearly equals the first pectoral ray, both are about $\frac{3}{4}$ of the length of the head. The lower caudal lobe, a little longer than the upper, slightly exceeds the length of the head. The first ventral and the second anal ray are nearly equal, a little shorter than the second dorsal ray. At Pinang this species is numerous in rivulets and in rice fields, when they are flooded.

Fam. SCOPELINOIDÆ.

Genus SAURUS, *Cuvier*, 1817. (Harpodon. *Lesueur*, 1825.—Laurida, [*Aristoteles*,] *Swainson*, 1839.—Triurus, *Swainson*, 1839.) Muzzle short; mouth extending far behind the eyes; edge of upper jaw entirely formed by the intermaxillaries; numerous pointed teeth in both jaws, on the palatals, tongue and pharyngeals, but none on the vomer; [*Saurus badi* has a few minute teeth on the vomer,] anterior dorsal a little behind the large ventrals; body, cheeks and opercles scaly; from 8 to 15 branchiostegous rays.

(3831) *Saurus badi*, Cuvier.

Syn. Russell, CLXXII. Badi Mottah.
Saurus badi, Cuv. R. A. II. 314 (1).
Saurus badimottah, Ruppell: Neue Wirbelth, Fische, 77.

Head above, back and sides above the lateral line dull greenish olive, or greyish green; rest of the body pale silvery white; cheeks and opercles pale silvery olive with rose-coloured and bluish reflections; dorsal rays pale yellowish, membrane hyaline minutely dotted with black; second dorsal pale flesh-coloured, anterior margin blackish; caudal yellowish, minutely dotted with black, posterior half blackish; anal and ventral rays pale yellowish, membrane hyaline; pectorals pale yellowish, posterior half blackish. Iris silvery olive. D 11 or 12—1 (adipose), C $19\frac{1}{2}$, A 10 or 11, V 9, P 15, Br. XII, XIII, or XIV. Inhabits *Sea of Penang, Malayan Peninsula, Singapore*, Coromandel. Total length: 1 foot. The length of the head is $\frac{1}{5}$ of the total. The horizontal diameter of the orbit is $4\frac{1}{2}$ in the length of the head; the distance across the forehead, as well as the distance from the orbit to muzzle, equals one diameter. The eye is covered by a broad, transparent adipose membrane with a circular pupillary aperture. The angle of the mouth is situated at the posterior third of the head. The teeth of both jaws are placed in 5 to 6 series, of which the internal one carries the longest and most distant teeth; the rest gradually decrease in length towards the external series of teeth which are minute, card-like and erect, not obliquely forwards pointed like the rest. With the exception of the anterior four or five anterior teeth of each palatal, the rest as well as the pharyngeals, hyoid and lingual teeth are all smaller and pointing backwards. On the vomer appears a double series of excessively minute pointed teeth, forming a short transversal line which unites the palatal series. The teeth of the vomer are deciduous, and may from their diminutive size easily escape observation. The vertical diameter at occiput is $\frac{1}{11}$, in front of the anterior dorsal $\frac{1}{7}$, and at the root of the caudal $\frac{1}{16}$ of the total length. The sides are covered by 11 longitudinal series of rounded, finely concentrically striated scales, with three radiating lines at the radical part. Each scale has a central rather obsolete keel. The lateral line occupies the sixth series which is a little nearer to the back than to the abdomen. It contains upwards of 60 scales, triangular, a little smaller than the rest, each with a small trifid tubercle in front of the central keel, which is sharper than that of the rest of the scales and forms a continued ridge. The latter becomes very marked behind the second dorsal, so as to resemble that of the *Scombroidæ*. The anterior dorsal occupies the middle of the back between the muzzle and the caudal; the second ray is the longest, $\frac{1}{4}$ of the length of the head; of which the extent of the base is $\frac{1}{7}$. The ventrals are placed in front of the preceding fin; the first ray commences in the centre between the muzzle and the first anal ray; the penultimate ray, the longest, is $\frac{2}{3}$ of the length of the head; outside the root of the fin appears an elongated scale, $\frac{2}{3}$ of the longest ray. The first anal ray commences opposite the centre, between the last dorsal ray and the root of the caudal; the second ray, the longest equals the extent of the base which is $\frac{1}{2}$ of the length of the head. The second small adipose dorsal is placed opposite the two posterior anal rays. The caudal is covered with minute scales; the upper lobe, which is generally a little longer than the lower, equals the length of the head. The length of the pectorals is $\frac{1}{2}$ of that of the head; in the axilla appears a short broad triangular scale. Single individuals occur at Pinang at all seasons. They are eaten by the natives, although they are reputed to be very insipid. *Saurus badi*,

Cuvier, belongs according to M. Valenciennes to a distinct genus, following that of *Saurus*, and M. Valenciennes has corrected the nomenclature as follows.

(3832) *Saurida*, Cuvier and Valenciennes, 1849. The palatals have on the inner side of the long band of teeth a small distinct group of sharp teeth, surrounded by minute asperities. The palatals consequently have two separate series of teeth, whereas in the genus *Saurus* they have but a single such. The internal ventral rays are not so elongated as those of *Saurus*; two oblong fossets on the sides of the palatals, but none in front of the velum palatinum, like those of *Saurus*.

(3833) *Saurida tumbil*, (Bloch.)

Syn. Salmo tumbil, Bloch, Tab. 430.
Russel: CLXXII. Badi Mottah.
Salmo tumbil, Shaw. V. 67.
Saurus badi, Cuv. R. A. 314. (1).
Saurus badimottah, Ruppell: Neue Wirbelth. Fische, 77.
Saurus argyrophanes, Richardson. Report 1845, 308.
Saurida tombil, Cuv. and Val. XXII. 500.

Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Siagapore*, Malabar, Coromandel, Vanikolo, Waigiou, Macao, Red Sea, Isle of France (Cuv. and Val. l. c.).

(3834) *Saurus trachinus*, Temminck and Schlegel.

Syn. Saurus trachinus, Temm. et Schl. Fauna Japan. Pisces, 231, Tab. CVI. Fig. 2.

Young. Head above, back and sides above the lateral line light greenish olive, rest of the body silvery white; above the lateral line three parallel light blue longitudinal bands: beneath the line three or four similar but paler bands, all commencing at the gill-opening, terminating at the root of the caudal; behind the posterior margin of opercle an oblique black spot terminating at the root of the pectoral; cheeks and opercles silvery light greenish olive, with light blue and rose-coloured reflections; caudal bright yellow; adipose dorsal pale yellowish olive; rest of the fins hyaline, anterior dorsal and ventral rays pale yellowish. Iris silvery light greenish olive. D 12 or 13—1 (adipose), C 19/9, A 15 or 16, V 8, P 12, Br. XII. Inhabits *Sea of Pinang*, Japan. Total length: 6 inch. The head bears a general resemblance to the Gen. *Trachinus*, Linne; the upper surface is scaleless, and like the infraorbitals full of minute radiating asperities; the central line of the head is smooth and forms a narrow sulcus between the orbital arched. The length of the head is 4¼ in the total length. The horizontal diameter of the orbit is ⅓ of the length of the head, the distance of the orbit from the muzzle is ⅔ diameter, of which the distance across the forehead is ½. The angle of the mouth is situated a little behind the anterior half of the head. In each jaw appear but two series of teeth; in other respects the dentition is similar to that of *S. badi*, but there are no teeth on the vomer. The subopercle, the largest, is rounded, membranous behind, and sends a narrow pointed process up between the triangular opercle and the narrow crescent shaped preopercle; the interopercle is triangular and but little smaller than the opercle. The vertical diameter at occiput is 6½, at the anterior dorsal ⅛, and at the root of the caudal 15½, in the total length. The body is covered by 11 longitudinal series of scales resembling those of *S. badi*, but those immediately behind the occiput have near the posterior margin some radiating short furrows. The lateral line occupies the fifth series, and contains upwards of 60 scales; those of the anterior half of the line consist of a small tubercle terminating in 4 to 8 digitations; the rest are simple, tubular. The line itself is much less raised than in *S. badi*. The first ray of the anterior dorsal is a little nearer to the muzzle than the last dorsal ray is to the root of the caudal. The third ray, the longest, is 7/11 of the head and equals the extent of the base, of which the posterior ray is a little more than ½. The ventrals are placed in front of the anterior dorsal; the first ray, the shortest, commences in the centre between the muzzle and the first anal ray; the sixth ray is the longest, equalling the third dorsal ray; the root of the fin is on each side enclosed by an elongated scale, ½ the length of the sixth ray. The first anal ray is placed much farther forwards than in *S. badi*: it commences in the centre between the first ventral ray and the root of the caudal. The rays are nearly equal, or about ⅓ of the extent of the base, which is but little shorter than the head. The minute adipose dorsal is placed at the posterior third of the distance between the last dorsal ray and the root of the caudal, opposite the posterior fifth of the anal. The caudal is but slightly cleft; each lobe equals the third dorsal ray. The pectorals are short triangular, slightly exceeding ⅓ of the head. The stomach is capacious, cylindrical, ¼ of the total length; its contents shrimps. The intestinal canal is a simple narrow tube, a little less than ½ of the total length; from pylorus commences a single series of 15 linear appendicula cœcopylorica, each about 1/12 of the length of the intestinal canal. Two individuals, of 5 and 6 inches in length, occurred together at Pinang in February 1845. The fishermen were not acquainted with the species. *Saurus trachinus*, Temminck et Schlegel, is the young of:

(3835) *Saurus myops*, (Forster.)

Luli of the Malays.

To the Synonymes of *Saurus nehereus*, (Buchan, Hamilton,) add: *Saurus ophiopon*, Cuv. and Val. XXII. 490. Head above, back and sides light grey or dust-coloured, semi-transparent like gelatine, with minute starlike black and brownish dots; anterior part of abdomen pale silvery bluish; rest whitish; cheeks and opercles pale silvery bluish, dotted like the body; fins transparent, coloured like the body but more closely dotted, so as to appear pale blackish. Iris bluish silvery minutely dotted with black. D 12 or 11—1 (adipose), C 19$\frac{1}{2}$, A 14 or 15, V 9, P 11 or 12, Br. XXIV or XXIII. Inhabits *Sea of Malayan Peninsula and Islands*, Chusan, Woosung, Canton, Madura, Java, Sumatra, Tenasserim, Mouths of the Ganges, Vizagapatam, Bay of Bengal, Bombay, Malabar. Total length: 11 inch. Measured obliquely from the muzzle to the posterior angle of the opercle, the length of the head is $\frac{1}{6}$ of the total. The diameter of the eye is $\frac{1}{5}$ of the length of the head; the distance from the muzzle is 2 diameter; that across the arched forehead 4. The angle of the mouth is at the posterior fourth of the length of the head; the jaws are equal. All the teeth are excessively slender, recurvous, and, like those of some of the *Gobioidæ*, erectile, but not flexible. They may be raised or laid down in the manner in which Cuvier describes the teeth of his genus *Salarias*, like the keys of a Piano. Those of the jaws and some of the palatals have a single barb at the posterior margin of the point; a few of the former are arrow-shaped. In both jaws appear three series of somewhat distant teeth: the external consist of excessively minute ones, the second of longer, and the internal series of the longest of all. Those of the lower jaw are longer than those of the upper, particularly three or four on each side of the symphysis. The pharyngeal and palatals consist of two series. The fourth anterior tooth of each palatal is very long. The tongue is very short, linear, and covered with fine teeth, like those of the hyoid bone and the upper margin of the branchial arches. The opercles are membranous, diaphanous and appear all blended together. The branchiostegous membrane is narrow, but it projects behind the posterior radiated angle of the opercle. The branchiostegous rays are excessively slender and flexible like hairs, and they gradually increase in length backwards. The posterior ones may be seen through the lower part of the opercle. The nostrils open vertically in front of the anterior margin of the orbit; the anterior opening is the larger. The upper part of the head is arched from side to side, and cellular, covered by a thin membrane, and like the rest of the head and body by diaphanous, deciduous scales. The latter are of moderate size, oval with concentrical rings. The lateral line, a little nearer the back than the abdomen, is slightly raised or keeled, and consists of about 44 rectangular membranous pieces, covered with scales like the rest of the body. The line is continued over the central pointed lobe of the caudal, and this portion containing 6 to 8 additional membranous pieces. All the scales are diaphanous and flexible, and cannot but with difficulty be distinguished in the fresh fish. The vertical diameter at occiput is $\frac{1}{6}$, at the anterior dorsal $\frac{1}{8}$, at the root of the caudal $\frac{1}{13}$ of the total length. The anterior dorsal is placed in the middle of the back, at equal distance from the muzzle and the root of

the caudal. The third ray, the longest, is $4\frac{3}{4}$ in the total length; the rest gradually decrease; the last is a little more than $\frac{1}{3}$ of the third ray, of which the extent of the base slightly exceeds $\frac{1}{2}$. The first ventral ray is placed opposite the first dorsal ray, at equal distance from the muzzle and the last anal ray. The fin extends to the middle of the anal, its length being $\frac{1}{3}$ of the total. Outside the root appears a very thin elongated scale. The first anal ray is placed at equal distance from the last dorsal and the root of the caudal; the third ray, the longest, is $7\frac{1}{2}$ in the total length, and twice the length of the last ray; the extent of the base equals that of the anterior dorsal. The adipose dorsal is rather large, elongated and placed opposite the posterior third of the anal fin. The caudal is divided in three pointed lobes, of which the upper and lower are about $\frac{1}{6}$ of the total length; the central lobe, composed of the three elongated central rays, is either equal to, or a little shorter than the former two; almost the whole of the fin is covered with minute scales. The pectorals are falciform and extend in the young to the last dorsal ray, but they become shorter with age, and then vary from a little less than $\frac{1}{2}$ of to $3\frac{1}{2}$ in the total length. They appear to have no axillary scale. The peritoneum is silvery; the stomach elongated, pyriform, thin and capable of enormous expansion; the fundus is arched, and separated from the rest by a constriction. The intestinal canal is narrow, cylindrical, scarcely $\frac{1}{2}$ of the total length. At the pylorus appears a series of 22 gradually decreasing cœcal appendages. The liver and spleen are very small. The fish is of most voracious habits, gorging itself with its own species and other fishes of nearly its own size, and *Crustacea* (shrimps). It is frequently taken with the stomach and the jaws expanded with prey. It is very short-lived, more so than either of the two preceding species, and the whole body becomes at certain seasons brilliantly phosphorescent. In the Straits of Malacca it is at all times very numerous, although less so than it is at the Sandheads or in the mouths of the Ganges. Although very rich, it is a great delicacy immediately after it is taken. Salted and dried it is also highly valued, and in this state it occurs in commerce under the denomination of "*Bombay Ducks*," ("*Bummaloh*" in Bengal), large quantities of which are annually exported from Bombay and the Malabar coast to all parts of India.

Fam. CLUPEOIDÆ.

Genus CHIROCENTRUS, (*Cuvier* 1817) *Valenciennes*, 1846. Body compressed, elongated, with small deciduous scales; abdomen trenchant, but not toothed; dorsal placed far back towards the tail, opposite the anal; pectorals pointed; in the axilla a bony, triangular, elongated appendage; ventrals excessively small; intermaxillary and upper maxillary with a single series of pointed horizontal teeth, of which one on each side of the symphysis longer than the rest; an oblique series of 5 or 6 card-like teeth on the palatals; a small oval group of velvety teeth on the anterior pterygoid, and some on the ala major; on each branch of the lower jaw a single series of long, but unequal, teeth, compressed, trenchant, lance-shaped; a single series of minute conical teeth along the margin of the tongue, on the hyoid bone and the margin of the branchial arches. Branchiostegous rays eight.

(3838) *Chirocentrus dorab*, (Forskal).

Paraug-Parang of the Malays.

Head above and back intense blue with sea green reflections; rest of the head and body shining silvery; fins hyaline, caudal and pectorals dotted with black; in some the caudal margins and the upper ray of the pectorals black; tongue black. Iris silvery; orbital margin bluish black. D 16 or 17, C $19\frac{7}{7}$, A 33 or 34, V 6 or 7, P 14 or 15, Br. VIII. Inhabits *Sea of Malayan Peninsula and Islands*, Zanzibar, Isle of France, Red Sea, Muscat, Malabar, China Sea, Isle of Buru, New Guinea, Celebes, Madura, Java, Sumatra, Coromandel, Bay of Bengal, Gangetic estuaries. Total length: 6 feet. The length of the head is $6\frac{1}{2}$ in the total; the depth at occiput $\frac{3}{4}$ of the length. The horizontal diameter of the eye is $\frac{1}{4}$ of the length of the head; the distance across the forehead $\frac{3}{4}$ of the diameter. The vertical diameter at the ventral slightly exceeds the length of the head. The lower caudal lobe is frequently a little longer than the upper, and exceeds by $\frac{1}{4}$ the length of the head. The fish is numerous at all seasons on the Malayan coast. Individuals six feet in length are at Pinang of rare occurrence. Although not eaten by Europeans, this fish is highly valued by the natives of the different countries where it is found. The Malays denominate it from the resemblance of the large teeth to their favourite chopping knife (*parang*) and they apostrophize it in a popular epigrammatic stanza ("pantun,") quoted

by Colonel James Low. (Dissertation on Pinang, &c. p. 181.)

Genus CHANOS, (*Lacep.* 1803) *Valenciennes* 1846. (Lutodeira, [*v. Hassel,*] *Ruppell*, 1828.) Mouth toothless; dorsal single; pectorals and ventrals enclosed by elongated scaly appendages; on each side of the deeply cleft caudal two scaly semilunar laminæ, each horizontally fixed to the upper and lowermost of the short, horizontal central rays; abdomen rounded; inside of œsophagus, lined by a spiral ridge the sides of which with numerous rounded papillæ, the margin with distant elongated papillæ; outside of œsophagus marked by a corresponding spiral linear impression; numerous appendicula cœcopylorica; intestinal canal very long.

(3839) *Chanos pala*, (Cuvier.)

Syn. Russell, CCVII. Palah Bontah. [In Mr Jerdon's memoir "*On the Fresh Water Fishes of Southern India*," in the *Madras Journal* Vol. XV. p. 344 the author refers a species of *Albula* ("*Butirinus maderaspatensis*, Jerdon") to Russell. No. CCVII. As the latter belongs to a genus very distinct from *Albula* (*Butyrinus*, vide infra), Russell's species cannot be identical with. "*Butyrinus maderaspatensis.*"]

Cyprinus (Leuciscus) pala, Cuv. R. A. II. 276 (1.)

Chanos nuchalis, Cuv. and Val. XIX. 197.

(*Adult.*) Head above and back glossy intense blue; sides above the lateral line lighter, silvery with green reflections, becoming paler immediately beneath the line; rest of the sides and abdomen silvery white; lips pale brownish; cavity of the mouth and tongue bluish white sparingly dotted with black; sides of the head shining silvery with lilac and rose coloured reflections; dorsal and caudal rays greyish white, and as well as their pale brownish membrane minutely dotted with brown; both fins broadly edged with blackish; the caudal semilunar laminæ pale horn-colour; pectorals and ventrals white, with the anterior half of their external surface powdered with blackish brown, their elongated scaly appendages shining silvery; anal white, anterior half sparingly dotted with black. Iris silvery, orbital half pale brownish. (*Young.*) Differs by the hyaline fins, of which the dorsal and caudal are but sparingly dotted with brown. D 15,C 19/8, A 11,V11,P 16,B.IV. Inhabits *Sea of Pinang, Malayan Peninsula*, Vizagapatam, Madras. Total length: 2 feet. The length of the head is 5¼ in the total; but in the very young 4¼. The depth at occiput is ⅓ of the length of the head. The eye, bordering upon the profile, is situated a little in front of the second third of the head. The horizontal diameter is 3⅓ in the length of the head. The distance across the forehead slightly exceeds the diameter. The thick adipose fold has a circular pupillary opening. In the young the eye is comparatively larger, the horizontal diameter slightly exceeding ⅓ of the head. The symphysis of the lower jaw carries a small rounded tubercle fitting into a corresponding notch of the upper, behind which is suspended a narrow crescent-shaped membrane. The small tongue is elongated and immoveable. The greatest vertical diameter, in front of the dorsal, is little less than the length of the head. The deepest portion of the body is covered by 26 longitudinal series of scales; the first six to eight scales of each series, of above as well as beneath the lateral line, are indeed somewhat larger than all the rest, but the size gradually decreases, and not abruptly, as represented in the figure of Russell. The latter is also incorrect in confining the larger and striated scales to the space *above* the lateral line, and the number of the longitudinal series is incorrect. The lateral line, composed of simple central tubes, declines towards the termination of the pectoral, from whence it continues straight on the thirteenth longitudinal series of scales to the middle of the caudal. It occupies 77 scales. The dorsal fin commences exactly in the middle between the muzzle and the root of the longest ray of the upper caudal lobe. The first three rays are undivided and gradually increase in length; the fourth, the longest, is ¾ of the length of the head. The upper margin of the fin is crescent-shaped, the last ray being elongated and nearly double the length of the penultimate. The base is enclosed between two series of elongated, obliquely set scales, of which there are thirteen on each side, gradually increasing in length so as to cover the lower half of the posterior rays. The caudal is deeply cleft, the lobes are 3½ in the total length; in one individual the uppor slightly exceeded the lower. The vertical diameter of the tail at the root of the caudal, is about ⅓ of the length of the head. Semilunar laminæ are closely pressed to the fin, with free convex margin towards the lateral line; the length of the straight margin or base is ⅘ of the horizontal diameter of the eye. In the adult the vertical diameter of the laminæ is ¼ of the diameter of the eye, but in the young it is less. The extent of the base of the anal fin equals its distance from the root of the caudal; the anterior ray is very small and, as well as the second and third, undivided; the last ray is the longest, terminating in a narrow point, its length ⅓ of the head. The base like that of the dorsal is enclosed between two series of elongated scales of which the last half covers the corresponding ray. The ventrals commence opposite the posterior half of the dorsal, or half-way between the first pectoral and the last anal ray. The first ventral ray slightly exceeds ½ the length of the head; the outer scaly appendage is nearly ⅔ of the first ray; the inner one is much shorter and broader, triangular. The pectorals commence

close to the abdomen, immediately behind the gill-opening; the first ray is about ¾ of the length of the head. The outer scaly appendage is very long, ¾ of the first ray; the inner one is broader and but half the length of the former. At Pinang single individuals occur at all seasons, and are highly valued for their very delicate flavour. The œsophagus is spindle-shaped, fleshy, exceeding half the length of the head by ⅓. The external surface is smooth, with a spiral, linear impression, corresponding to the internal spiral ridge, which makes 21 very oblique turns. The ridge is of a triangular form, both sides are divided by numerous backwards-directed linear ridges, each of which carries a great number of small, soft, pointed papillæ; the free margin towards the cavity of the œsophagus is smooth, but on that of the fourteen anterior turns appear some distant-pointed, backwards-directed papillæ, which are much longer than those of the sides. The stomach consists of two portions, of which the anterior is cylindrical, narrow at cardia, bent like a double horse-shoe, and then joins the short, pyriform posterior portion. The latter is very fleshy, hard, gizzard-like. Both portions are lined by 6 to 10 longitudinal rather large folds; towards pylorus the coats are very thick, forming there two rounded hard protuberances. The length of the stomach slightly exceeds 3¾ in the total. In one examined it contained some remains of vegetable matter, and green mucus. The duodenum is surrounded by numerous appendicula cœcopylorica, each of which divides in two or more portions, of which an iunumerable mass, extending about 1⅛ inches from pylorus, envelops the intestine. Those nearest the pylorus are the longest, about one inch in length. The intestines, throughout of nearly uniform diameter, form many circumvolutions; from pylorus their length is about 3½ times that of the fish; but including œsophagus and the stomach, the length of the entire intestinal canal is a little less than four times the total length of the fish. The liver and the spleen are very large, the former elongated single-lobed; the latter of a beautiful black with purple reflections. The air-vessel is very large, spindle-shaped, terminating behind in an elongated point; the anterior margin is straight with a short pointed process on each side. It communicates with the anterior portion of the stomach through a short canal proceeding from the anterior part of the lower surface. Its coats are very thin, white, covered by the black peritoneum. In a male, 2 feet in total length, the intestinal canal was of the following dimensions.

Œsophagus,	0	feet 2⅜	inch.
Anterior portion of stomach	0	„ 5	„
Posterior do.	0	„ 1⅛	„
Intestines,	7	„ 0⅜	„
	7	feet 9⅛	inch.

The description and figure of Russell, No. CCVII. *Palah Bontah*, establish beyond doubt the identity of the present species, which Dr. Ruppell believes to be identical with *Mugil chanos*, Forskal. The figure of *Lutodeira chanos*, Ruppell [Atlas, 18, Tab. 5. Fig. 1. Syn. *Mugil chanos*, Forsk, 74, No. 110.—*Mugil salmoneus*, J. R. Forster, Msc. IV. 14.—*Chanos arabicus*, Lacep. V. 399,—*Palah Bontah*, Russell, CCVII. —*Lutodeira indica*, Van Hasselt, apud Ferrusac] gives indeed the exact proportions of the fish observed at Pinang, and the anatomical details, the singular structure of the œsophagus and stomach of which Dr. Ruppell gave the first account, also correspond. But the length of the intestinal canal has been omitted, and till that is known, the identity cannot be decided. M. Valenciennes considers Russell's *Palah Bontah* to be distinct from *Mugil chanos*, Forskal, in consequence of the eight or nine oblique series of larger scales immediately behind the head. But, as observed above, Russell's figure is not correct; besides, it appears from references to Russell's figure of *Lutodeira chanos*, to M. Valenciennes' of *Chanos lubina*, (XIX. Pl. 567,) and lastly from inspection of a young individual of *Chanos tolo*, (Cuvier,) that also these species present behind the head a few series of scales a little larger than the rest. Leaving this character aside, the present species offers an anatomical difference from *Mugil chanos*, Forskal, [*Chanos arabicus*, Cuv. and Val. XIX. 187.] of which according to M. Valenciennes the intestinal canal, from pylorus, measures eight times the length of the body. As observed above, in the present species the canal is about 3½ times, and with œsophagus and the stomach, a little less than four times the total length.

(3840) *Chanos tolo*, (Cuvier.)

Syn. Russell, CCVIII. Toolelee,
Cyprinus tolo, Cuvier, R. A. II. 276 (1).
Chanos chloropterus, Cuv. and Val. XIX. 195.

Young. Head above and back intense blue, lighter, silvery with green reflections above the lateral line; the rest and abdomen silvery white; sides of the head shining silvery with lilac reflections; fins yellowish white, dorsal and caudal minutely dotted with black, giving the margins a blackish appearance. Iris silvery, orbital margin blackish. D 17, C 19⅜, A 10, V 11, P 15, Br. IV. Inhabits *Sea of Pinang*, River of Madepollam (Godavery). Total length: 4⅜ inch. This species greatly resembles *C. pala*. It differs, however, in the following characters. The dorsal fin is placed a little farther forwards, the first ray, undivided as well as the succeeding four, rises in the centre between the muzzle and the commencement of the upper caudal lobe. The ventrals also are situated a little more forwards; the first ray commences at equal distance from the first pectoral and the eighth anal ray. The

extent of the base of the anal is shorter than the space between the last anal ray and the root of the lower caudal lobe. In front of the dorsal fin the body is covered by 24 longitudinal series of scales, of which the lateral line occupies the eleventh from above. The scales of the oblique series behind the head are a little larger than the rest, which, although they appear smaller than in *C. pala*, are not so proportionally, nor does Russell's figure represent them so. The four caudal semilunar laminæ resemble those of the former species. A single young individual was taken in a fishing-stake off the coast of Pinang in March 1845. The fishermen asserted that it is an inhabitant of rivers, and but rarely enters the sea.

Genus ALBULA, (*Gronov.* 1763) *Valenciennes*, 1846. (Butyrinus, [*Commerson*] *Lacep.* 1808). Body fusiform, covered with numerous hard, firm scales, disposed in longitudinal series, one such before and behind the dorsal fin, (on the keel of the back) of a little larger scales; in the species here described they are not larger than the rest, head large, naked, above with the grooves between the keels of the bones appearing through the skin; eye with a thick adipose lid; muzzle conical, pointed, projecting far beyond the lower jaw; dorsal small, ventrals commencing opposite the posterior part of the latter; card-like teeth in the upper intermaxillaries and the lower jaw, on the vomer palatals and pharyngeals; small globular teeth on the spheroid, pterygoid, and hyoid bones.

(3841) *Albula erythrocheilos*, Cuv. and Val.?

Syn. Albula erythrocheilos, Cuv. and Val: XIX. 352, Pl. 540?

Head above and back blackish silvery; sides and abdomen frosted silvery, the edges of the scales shining; infraorbitals and opercles brilliant silvery; on each side of the yellowish white muzzle a short backwards and downwards directed black line, not, however, joining its neighbour on the lower surface; in the small groove containing the apertures of the nostrils a minute crescent-shaped black spot bordering the anterior half of the apertures; a gamboge line from the posterior part of the second infraorbital borders above the single series of scales and extends to the anterior margin of the preopercle; margin and cavity of the mouth white; dorsal rays yellow; their upper fourth blackish; membrane pale brownish dotted with black; caudal yellow, posterior margin blackish; anal silvery hyaline; ventrals hyaline, rays of the anterior half and the pectorals bright gamboge. Iris silvery, orbital margin pale golden. D 18 or 19, C 19 $\frac{8}{8}$, A 8 or 9, V 11, P 17 or 18.

Br. *left* XIV, *right* XIII.
or „ XVI, „ XV.

Inhabits *Sea of Pinang*. Total length: $9\frac{4}{8}$ inch. The length of the head is $4\frac{1}{2}$ in the total; the depth at occiput slightly exceeds half the length. The parietal protuberances and the posterior keels of the frontal bones are sufficiently developed to make the space between them appear hollowed; the sutures of the frontals and parietals form an acute angle in front of the eye; the frontals are slightly convex; the internal cavernous keels are sharp, so as to deepen the narrow central groove. The nostrils open a little behind the second half between the muzzle and the eye; they are situated in a small oval longitudinal groove, the upper and lower margins of which are raised, so as to form sharp keels, the upper one of which rises on the profile like a short arch. The eye occupies the middle of the side of the head, bordering on the profile, which is slightly arched by the lateral part of the frontal bone which forms the roof of the orbit. In front of the anterior part of the orbital margin of the frontal appears a narrow bone, analogous to the supraorbital of *Cyprinoidæ*. The horizontal diameter of the eye is $4\frac{1}{3}$ in the length of the head, of which the distance across the forehead is but $\frac{1}{4}$. The thick adipose fold covering the eye has a vertically elliptical aperture corresponding to the pupil which, however, is circular. In form the seven infraorbital bones and the opercles resemble those of *Albula macrocephala*, (Lacep). Between the cheek and the horizontal part of the preopercle appears a single series of 7 to 9 scales, but little smaller than those of the body. The tongue and teeth resemble those of the latter species. In the adult there are no teeth on the upper maxillary bone, but in an individual $8\frac{4}{8}$ inch in length, four small pointed distant teeth appeared along the margin of the left branch, and on the right two immediately behind the intermaxillary, and one tooth close to the angle of the mouth. A small accessorian maxillary appears at the posterior margin of each branch. The thin narrow interopercle is arched, with the convex margin downwards, occupying the sides of the throat. In four individuals examined the left branchiostegous membrane overlapped the right and presented one additional ray. Two measuring $9\frac{4}{8}$ inch, and one $8\frac{4}{8}$ inch in length, had 16 branchiostegous rays in the left, 15 in the right membrane. A fourth, $9\frac{4}{8}$ inch in length, had 14 in the left, 13 in the right membrane. The two or three anterior rays are short, linear, and not sabre-like as the rest, and as they are hid by the lax membrane, they may easily escape observation, unless they are brought to view by dissection. The greatest vertical diameter of the body, in front of the dorsal, is $\frac{1}{6}$ of the total length. The scales are disposed on 15 longitudinal series, and in general form resemble those of *A. macrocephala*, (Cuv. and Val. XIX. Pl. 573.) Examined through a compound microscope, (385 linear), the longitudinal striæ appear to be composed of horse-shoe-like protuberances,

not of bead-like strings, as in *macrocephala*. The lateral line occupies the ninth series; it follows for a short distance the gill-opening, and then continues straight in the middle of the side to the root of the caudal. It is composed of simple central tubes, on 72 to 78 triangular scales, somewhat smaller than the rest. All the fin-membranes are covered by minute oblong scales, either transparent or silvery. The dorsal fin commences a little in front of the centre between the muzzle and the root of the caudal. The central series of scales of the back are not larger than the rest, but on the contrary, somewhat smaller. The ventrals commence not behind the posterior dorsal ray, but opposite the 13th or 14th. In form all the fins resemble those of *A. macrocephala*, but the upper caudal lobe, equal the length of the head, is longer than the lower. In three individuals the difference scarcely exceeded $\frac{1}{8}$, but in a fourth the lower lobe was but $\frac{2}{3}$ of the upper one. The stomach is elongated cylindrical, capacious, very thin. It contained remains of small shrimps. Round the pylorus appear fourteen large appendicula cœcopylorica. The intestinal canal is simple, little more than half the total length of the fish. The other viscera resemble those of *A. macrocephala*. Four individuals were taken in February 1845 in fishing-stakes off the coast of Pinang. The fishermen, evidently not well acquainted with the species, asserted it to be of rare occurrence, and highly valued. Out of water it soon expires and becomes soft. This fish nearest agrees with *A. erythrocheilos*. It differs in the number of branchiostegous rays, but as M. Valenciennes drew up his description from a single specimen, and as the character is liable to individual variations, it is without actual comparison of specimens not sufficient to distinguish species, which so nearly resemble each other as those of the genus *Albula*.

Genus DUSSUMIERIA, *Valenciennes*, 1847. Form of the body resembling Gen. *Sardinella*, but the abdomen smooth, not toothed; fine teeth in the jaws, on the tongue, palatal and pterygoid bones; those of the two latter resembling a fine rasp.

(3842) *Dussumieria acuta*, Cuv. and Val.

Syn. Dussumieria acuta, Cuv. and Val. XX. 467. Pl. 606.
Tamban bulat of the Malays.

Head above, back and upper third of the sides deep glossy blue, bordered by a longitudinal band of pale copper-red; the rest of the head and body shining silvery; dorsal hyaline, minutely dotted with black along the base; caudal whitish or yellowish minutely dotted with black, posterior margin blackish; rest of the fins hyaline; jaws minutely dotted with black; symphysis of the upper jaw black; on each side of that of the lower a short dotted black line; tongue bluish, dotted with black. Iris silvery, orbital margin blackish. D 19 to 21, C $19\frac{1}{2}$, A 14 to 17, V 8, P 13 or 14, Br. XV. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Malabar, Coromandel, Bencoolen. Total length: 6 inch. The length of the head is contained $4\frac{3}{4}$ times in the total; the depth at occiput $2\frac{1}{3}$ in the length of the head. The eye, bordering on the profile, occupies the middle of the head; the horizontal diameter is $\frac{1}{3}$ of the length of the head; the distance across the forehead $\frac{3}{4}$ of the diameter; the thick adipose fold covering the eye has a small circular pupillary opening. The left branchiostegous membrane slightly overlaps the right, but the number of the rays of both is equal. The greatest vertical diameter in front of the dorsal is $5\frac{1}{2}$ in the total length. The scales are small, rounded and very deciduous. The dorsal fin commences at equal distance from the muzzle and the centre of the posterior caudal margin. Single individuals of this species occur at Pinang at all seasons, but numbers from June to September. It is highly valued for its delicate flavour, and passes commonly as a 'Sardine.' The latter denomination it shares, however, with *Clupeonia perforata*, (vide infra,) with which it is also confounded by the Malays under the common name of *Ikan tamban*. Both species have been prepared as 'Sardines a huile.'

Genus ELOPS, *Linne*, (1766) *Cuv. and Val.* 1846. (Megalops, *Lacepede*, 1803). Branchiostegous rays remarkably numerous; a single bony plate between the branches of the lower jaw under the branchiostegous membrane; gape very large; intermaxillaries short; maxillaries long, free; both, as well as the palatals, vomer, pterygoids, sphenoids, lower jaw, lingual and hyoid bones covered with fine velvety teeth; body elongated, and as well as the abdomen, rounded; above and below at the root of the caudal a more or less elongated, spine-like scale; pectorals and ventrals with an elongated scaly appendage; last dorsal ray in some terminating in an elongated filament.

Inhabits *Sea of Pinang*, Isle of France, Java, Celebes, Madura, Red Sea, Coromandel, China Sea, Japan, Senegal, New York, New Orleans, St. Domingo, Martinique, Mexico, Surinam, Brazil. Total length: 11 inch. The length of the head is $\frac{1}{4}$ of that of the body, the caudal not included, or with the latter 4$\frac{4}{5}$ times in the total The length at occiput is $\frac{1}{2}$ of the length of the head. The eye bordering on the profile, occupies the second fourth of the head, the horizontal diameter is a little less than $\frac{1}{4}$ of the head; the distance across the forehead is a little less than $\frac{2}{3}$ of the diameter. The adipose fold surrounding the orbit forms a large circular opening, corresponding to the pupil. The left branchiostegous membrane overlaps the anterior half of the right. The elongated bony plate between the branches of the lower jaw exceeds by $\frac{2}{5}$ the horizontal diameter of the eye. The greatest vertical diameter, in front of the dorsal, is $\frac{1}{8}$ of the total length. The lateral line is composed of a simple central tube on each scale. It follows nearly the middle of the side, proceeding straight to the centre of the posterior margin of the caudal. The stomach of a solitary young individual, observed at Pinang in February 1845, contained remains of small Crustacea and Fishes.

Cuv. and Val., „ 18, „ 30. „ 25, „ 11, „ 14, „ XXIV—XXV.

Inhabits *Sea and freshwater, Pinang, Malayan Peninsula*, Freshwater and coasts of Otaheiti, Isles of Tanna and Buru, China Sea, Port Essington, Polynesia, Madagascar; Rivers of Java, freshwater and Sea of Madura, Celebes, Malabar, Coromandel, Gangetic estuaries. Total length: 1 foot. The length of the head is 4$\frac{2}{5}$ in the total; the depth at occiput $\frac{3}{4}$ of the length. The horizontal diameter of the eye is 2$\frac{3}{4}$ in the length of the head, the distance across the forehead is $\frac{2}{3}$ of the diameter. The greatest vertical diameter, in front of the dorsal, equals the length of the head. The scales are disposed on twelve longitudinal series, of which the sixth carries the lateral line. The latter declines towards the dorsal from whence it continues straight to the caudal. In the adult it occupies from 38 to 41 scales, each carrying a rather indistinct central tube, from above and below which radiate backwards from six to eight fine branches. The left branchiostegous membrane partially overlaps the right. The elongated bony plate between the branches of the lower jaw slightly exceeds the horizontal diameter of the eye. Of the anterior dorsal rays the fourth or the seventh is the longest, about $\frac{2}{3}$ of the length of the head. The last dorsal ray is divided in two portions of which the posterior is again divided in two filaments, provided in front and behind with a narrow loose membrane. The filament in some reaches the root of the caudal but it is frequently much shorter, particularly in

old individuals. A young one, 4½ inch in length, differed in, contrary to the generality of fishes, having the eye proportionally smaller than the adult; the lateral line, occupied but 29 scales, each carrying a very distinct central tube with two or three short spine-like branches; the dorsal filament was very short, its length less than the longest of the anterior rays; the left branchiostegous membrane contained but 23 rays, the right one less, and the colour of the head and back were paler than in the adult. At Pinang single individuals are taken at all seasons in the fishing-stakes off the coast; but those inhabiting fresh-water are numerous. In both localities their food is small fishes and crustacea, but in the latter they also prey upon insects. Notwithstanding their numerous fine bones they are valued for their flavour, which loses nothing by their being introduced in tanks where they rapidly multiply and fatten. M. Valenciennes considers *Megalops setipinnis*, Richardson, [*Ann. Nat. Hist.* X. 493, and *Report*, 1845, 310.] to be identical with, and *M. curtifilis*, Richardson, [*Report*, 1845, 310.] to be the young of the present species.

Genus PELLONA, *Valenciennes*, 1847. (Platygaster, *Swainson*, 1839). Preoccupied by *Platygaster*, Latreille, 1809 (*Hymenoptera*). Teeth in the jaws, on the palate, pterygoid bones and on the tongue, but not in the vomer; body compressed; ventrals in front of the dorsal; anal elongated; abdomen strongly toothed; air-vessel communicating with œsophagus by a small tube inserted at the extremity of the stomach.

(3845) *Pellona affinis*, (Swainson).

Syn. (*Icon*). Clupea affinis, Gray: Illustr. Ind. Zool. I, Pl. 96.
Platygaster affinis, Swainson, II. 294.
Clupea (Ilisha) affinis. Richardson, Report: 1845, 206. Note.
Pellona grayana Cuv. and Val. XX. 315.

Head above and back greyish green minutely dotted with black; lighter, silvery above the lateral line; rest of the sides, abdomen, cheeks and opercles silvery; dorsal, caudal and anal yellow; the external half of the two former minutely dotted with black; rest of the fins hyaline. Iris silvery, orbital margin blackish. D 16, C 19½, A 50 to 52, V 7, P 15, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, China Sea, Bay of Bengal. Total length: 1 foot. The length of the head is ⅕ of the total. The horizontal diameter of the eye is 4½ in the length of the head; the distance across the forehead slightly exceeds one diameter. The greatest vertical diameter, in front of the dorsal, is 3¾ in the total length. The dorsal commences in the middle between the muzzle and the centre of the posterior caudal margin. The caudal lobes are equal: ⅙ of the length of the head. The anal commences opposite the posterior fourth of the dorsal. The small ventrals are situated opposite the second third of the distance between the muzzle and the root of the caudal. Smaller individuals of this species are numerous at Pinang at all seasons, and are consumed fresh or dried by the natives.

Genus RACONDA, *Gray*. [What has been published of this species appears to be confined to the figure in *Hardwicke's Illust. of Ind. Zool.* of *Apterygia ramcarate*, and a very short notice in *Zoological Miscellany*. But for the absence of the dorsal fin, the resemblance to *Pristigaster tartoore*, Cuvier, (Russell, CXCIII. Tartoore), is so striking, that it is not surprising, that M. Valenciennes should have considered the undescribed figure of *Apterygia ramcarate* ("*hamiltonii*," as quoted in *Hist. des Poiss.* XX. 333), to represent a mutilated specimen of *Pristigaster tartoore*. The following is Mr. Gray's description of Raconda russelliana: "*Silvery; Saugar Roads. A species distinguished from the want of the fin by the fishermen; there are two specimens in British Museum, neither shewing the slightest indication of that organ.*" (Zool. Miscell. l. c)] Dorsal fin none; rest like *Pristigaster*.

(3846) *Raconda russelliana*, Gray.

Syn. Raconda russelliana, Gray: Zool, Miscell. 9.
(*Icon*). Apterygia ramcarate, Gray: Ill. Ind. Zool. II. Pl. 92. Fig. 1.
Pristogaster (Apterygia) Swainson, I. 277.
Apterygia hamiltonii, Cuv. and Val. XX. 333.

Head above and back deep blue, upper third of the sides polished, copper-coloured; rest of head and body shining silvery with mother-of-pearl reflections. Behind the upper part of the opercle a black spot; caudal pale yellowish minutely dotted with black, particularly towards the posterior margin; anal and pectoral rays yellowish or white, membranes hyaline. Iris silvery, orbital margin blackish blue. D 0, C 19½ A 83 or 84, V 0, P 12, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Bay of Bengal, Mouths of Ganges. Total length; 8 inch. The length of the head is 6½ in the total. The horizontal diameter of the eye is 3½ in the length of the head; the distance across the forehead is ⅔ of the diameter. The eye occupies the middle of the length of the head, and is situated close to the concave profile without bordering upon it. The infraorbital is narrow, elongated much too short to cover the maxillary. The intermaxillaries are short, narrow, linear and fixed transversely across the muzzle. The upper maxillary bone is much longer and broader than in *Pristigaster tartoore*; when the mouth is opened it projects beyond the throat, and when closed it extends to opposite the posterior margin of the

orbit; the length is $\frac{1}{3}$ of that of the head, the breadth $\frac{2}{3}$ of the diameter of the eye; the upper extremity is obliquely truncated, the lower forms a rather long, slightly backwards arched point. The lower jaw projects a little beyond the upper, which the branches equal in breadth, but they are shorter. The teeth of both jaws are very minute and placed in a single series; the rest are velvety or like a fine file. The mouth is small; the tongue free, flattened, oval. The opercle is triangular with the posterior extremity rounded or less pointed than in *P. tartoore*. The pre-opercle is narrower, and scarcely broader than the arched sub-opercle and interopercle, which two latter are proportionally broader in the present species. The branchiostegous membrane is small; its two anterior rays short and slender; the posterior four broad and flattened. The profile of the head is concave, rising to a little behind the occiput, from whence the back gently declines towards the root of the caudal. The abdominal arch continues increasing towards the root of the anal, from whence the profile gradually ascends The greatest diameter of the body, at the root of the pectorals, slightly exceeds $\frac{1}{5}$ of the total length; at the occiput it is $\frac{1}{6}$; at the root of the caudal it is about $\frac{1}{3}$ of the length of the head. The lateral line commences high up from the supra-scapular bone, and continues close to the profile of the anterior third of the back when it suddenly terminates. Another fine line follows the upper fourth of the side to the root of the caudal. The scales are of moderate size, oval, excessively thin and so deciduous, that the exact number cannot be ascertained. The trenchant abdominal profile contains upwards of 38 spines. The caudal is deeply cleft, the lower lobe, longer than the upper, equals the length of the head. The distance from the muzzle to the anal is $2\frac{1}{2}$ in the total length. The extent of the base is $\frac{1}{2}$ of the total length, (in *P. tartoore* it is little more than $\frac{1}{3}$,) the length of the rays does not exceed the horizontal diameter of the eye. The first pectoral ray, the longest, is situated nearly in the centre of the vertical diameter; it is broad, sword-like, with distinct articulations; its length is a little less than the head. At Pinang individuals from 4 to 6 inches in length are numerous at all seasons, although less so than they are at the Sandheads and the mouths of the Ganges. The Bengal fishermen denominate the species "*Potassah-Fessah* or *-Phasah*." "*Fessah*" or "*Phasah*," as Buchanan Hamilton observes, is in Bengal a generic term, particularly applied to *Engraulis phasah* (Buchan.) and *E. telarah*, (Buch.) It is a heavy swimmer, and like the rest of *Clupeoidæ*, expires immediately on leaving its element. It is chiefly consumed in a dried state.

Genus CLUPEONIA, *Valenciennes*, 1847. Teeth on the tongue and pterygoid bones; palatals, vomer and jaws toothless. In the species here described a single series of 4 to 6 minute deciduous teeth appears on each side of the symphysis of the lower jaw.

(3847) *Clupeonia perforata*, Cantor.

Syn. Tamban nepis, or Tamban patul of the Malays.

Head above yellowish green; back and upper third of the sides bluish green with silvery reflections; muzzle and chin blackish; rest of the head and sides and abdomen shining silvery with rose-coloured and ultramarine reflections; dorsal bright yellow, upper half minutely dotted with black; a black spot over the root of the anterior four rays; caudal pale bluish green, posterior half minutely dotted with black; rest of the fins white. Iris silvery, orbital margin black. D 17 to 20, C $17\frac{2}{6}$, A 19 or 20, V 8, P 15, Br. V. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Sumatra. Total length: $5\frac{6}{8}$ inch. The general form is elongated, compressed; the abdomen slightly more arched than the back. The length of the head is $\frac{1}{5}$ of the total; the eye is placed a little nearer the muzzle than the gill-opening; the horizontal diameter is a little less than $\frac{1}{3}$ of the head, but equals the distance across the forehead. The muzzle is bluntly pointed, the lower jaw very little longer than the upper. The small tongue is elongated oval; in the middle a little behind the apex appears a single series of very minute pointed teeth; on the palatals they are numerous but distant; the four to six on each side of the symphysis of the lower jaw are less minute; all are deciduous. The vertical diameter at occiput is $\frac{3}{4}$ of the length of the head; the greatest vertical diameter of the body, in front of the dorsal, is $\frac{1}{4}$ of the total length. The dorsal is placed at equal distance from the muzzle and the root of the caudal; the extent of the base is $2\frac{1}{2}$ in the length of the head; the upper margin is falcated; the fourth and fifth, the longest rays, equal the extent of the base; the last ray is elongated, $\frac{1}{2}$ of the fifth ray. The caudal is deeply cleft; the length of the lobes slightly exceeds $\frac{1}{4}$ of the total length. The distance from the caudal to the anal equals the horizontal diameter of the eye; the extent of the base of the anal is $\frac{2}{3}$ of the head; the rays are $\frac{2}{3}$ of the diameter of the eye, but the last is a little elongated. The ventrals are placed opposite the middle of the dorsal, at equal distances from the root of the upper pectoral and the first anal ray; their length is $2\frac{1}{2}$ in the head. The length of the pectorals is $\frac{3}{4}$ of the head. The scales are very deciduous, thin, and large, their circumference nearly equalling the eye. They have excessively fine vertical lines, and besides three larger distant ones, traversing the whole height of the scales; parallel to the posterior margin appears an irregular series of minute oval holes. There are eleven series on each side, and about 45 scales between the gill-opening and the caudal. Single

individuals occur at Pinang at all seasons, but great numbers during June, July and August. They are of delicate flavour and pass in the settlements of the Straits under the denomination of 'Sardines,' in imitation of which they are sometimes preserved in oil. A resemblance to *Alausa argyrochloris*, Cuv. et Val. (vol. XX. p. 440) is farther increased by the impossibility of perceiving the teeth either in fresh state or in specimens preserved in spirits of wine. They require the aid of a lens to be distinguished in the skeleton. The general form, the yellow dorsal fin with a small black spot give the present species a certain resemblance to *Meletta venenosa*, Cuv. et Val. (vol. XX. p. 377). Some specimens of *Clupeonia perforata*, procured by W. T. Lewis, Esq. Assist. Resid. Councillor, Pinang, were accompanied by the following account of a phænomenon witnessed by that gentleman during his official residence at Bencoolen. In 1822 great numbers of what was supposed to be this identical species, presented the unusual appearance of having red eyes. Many natives after having eaten these fishes, were suddenly attacked with violent vomiting, which in cases where remedies were not immediately applied, was known within an hour to terminate fatally. At the same time such of these fishes with the ordinary silvery eyes, were as formerly eaten with impunity. This phænomenon reoccurred at Bencoolen during the seasons of 1823 and 1825, but not of 1824. It was surmised that the poisonous fishes had fed on a gelatinous substance which at that season exudes from the beautifully coloured coral reefs on that part of the coast of Sumatra. It is, however, more probable that the poisonous fishes were shoals of *Meletta venenosa*, an inhabitant of the Seychelles and the neighbouring seas, which happened in those seasons to visit Sumatra. M. Valenciennes describes this fish as being poisonous, and producing effects as noted above. In the Straits of Malacca *Clupeonia perforata* has never been known to produce bad effects.

Genus KOWALA, *Valenciennes*, 1847. Minute teeth in the jaws and on the pterygoid bones; tongue, vomer and palatals [Minute teeth, deciduous like the rest, appear on the palatals of the two species described.] toothless.

(3848) *Kowala thoracata*, Cuv. and Val.

Syn. Russell, CLXXXVI. Kowal.
Clupea kowal, Ruppell: Neue Wirbelth. Fische, 79.?
Kowala thoracata, Cuv. and Val. XX.363.

Head above and back deep blue with green reflections; upper third of the sides silvery sea-green; rest of the body, cheeks and opercles shining silvery with mother-of-pearl reflections; upper part of the opercle pale bluish dotted with black; dorsal and caudal pale yellow greenish, sparingly dotted with black, particularly towards the margin; in some individuals a vertical elongated blackish spot at the root of the five central rays; rest of the fins white. Tongue and inside of the mouth minutely dotted with black. Iris silvery, orbital margin black. D 19, C 19$\frac{4}{5}$, A 21 or 22, V 8, P 15, Br. VI. Inhabits *Sea of Pinang*, Coromandel, Red Sea. Total length: 5$\frac{4}{5}$ inch. The length of the head is $\frac{1}{4}$ of the body, $\frac{1}{5}$ of the total length. The horizontal diameter of the eye slightly exceeds $\frac{1}{3}$ of the length of the head; the distance across the forehead is $\frac{2}{3}$ of the diameter. The eye is covered by a thick adipose duplicature with a vertically elliptic aperture over the circular pupil; it occupies the middle of the distance between the muzzle and the posterior margin of the opercle, and borders on the profile. The figure of Russell represents the eye much too small, probably owing to the adipose fold having been overlooked. On the surface of each of the posterior frontal bones appear upwards of 11 backwards radiating lines. In the individuals examined at Pinang there appeared from six to eight teeth in the lower jaw, and some on the palatal and pterygoid bones, but none in the upper maxillaries, intermaxillaries, nor in the vomer. These teeth are so minute that they require to be seen through a lens in dried specimens, and they are so very deciduous that their number and position vary not only individually, but from side to side. The scales of the body are large, rounded, very thin and deciduous; those of the back and upper third of the sides have each upwards of 16 longitudinal striæ. The sides are covered by 11 longitudinal series of scales, of which there appear to be upwards of 45 in the longest series. There are 35 spines on the abdominal profile, the scales of which resemble in breadth those of the species of *Pellona*. The greatest vertical diameter of the body, in front of the dorsal, is a little less than $\frac{1}{4}$ of the total length. The dorsal occupies the middle of the distance between the muzzle and the root of the caudal; the fourth ray, the longest, equals the extent of the base, which is ^{1} of the greatest vertical diameter of the body. The fin his half covered by an oblique backwards rising series of scales which almost hide the last rays. The caudal is deeply cleft, the lobes exceed by $\frac{1}{6}$ the length of the head. The scaly anal rays are vey short; the last slightly elongated; the extent of the base is $\frac{1}{3}$ of the length of the head; its distance from the root of the caudal is $\frac{1}{3}$ of the extent. The ventrals are situated opposite the centre of the dorsal, exactly in the middle between the root of the first pectoral and anal rays; their length is $\frac{1}{3}$ of the head. The length of the pectorals is $\frac{1}{3}$ of the head. At Pinang single individuals are of rare occurrence.

(3849) *Kowala lauta*, Cantor.

Syn. Clupea kowal, *Clupea kowal*, Ruppell, vide *Kowala thoracata*, Cuv. and Val.

Temm. et Schlegel: Fauna Japon. Pisc. 235, Tap. CVII. Fig. 1.

Anterior half of the head above greenish grey dotted with black; posterior half and back intense glossy blue; upper half of the sides light golden green; rest of the body shining silvery with mother-of-pearl reflections; behind the upper part of the opercle a rounded yellowish brown spot dotted with black, from which proceeds along the upper fourth of the side a yellowish brown band, terminating at the upper fourth of the root of the caudal; cheeks and opercles shining silvery with golden and sky-blue reflections; the temples minutely dotted with black; dorsal bright gamboge, anterior and upper margin blackish; caudal pale greenish yellow, upper and posterior margin blackish; rest of the fins white. Tongue and cavity of the mouth minutely dotted with black. Iris silvery, orbital margin blackish. D 19, C 19$\frac{5}{6}$, A 16 or 18, V 8, P 15, Br. VI. Inhabits *Sea of Pinang*, Japan. Total length: 6 inch. In addition to the colours and the number of anal rays this species presents the following characters distinguishing it from *K. thoracata*. In the intermaxillaries and upper maxillaries appear single, widely spread, pointed teeth; in the lower jaw from 8 to 12 such very little larger; those on the palatal and pterygoid bones are more numerous, but also with irregular intervals, indicating that the teeth are deciduous. All are so minute that they cannot be seen in fresh specimens, and in dried ones but through a lens. The fifth dorsal ray, the longest, is less than $\frac{1}{2}$ of the greatest vertical diameter of the body, and equals the extent of the base of the fin; the last ray is a little elongated. The last anal ray is also a little elongated, and extends halfway to the root of the caudal. The ventrals are placed more forwards than in *K. thoracata*; the first ray commences opposite the second third of the dorsal, and its distance from the first anal ray exceeds by $\frac{1}{5}$ that from the root of the first pectoral ray. The sides are covered by 11 longitudinal series of scales, the longest series containing about 35 scales. The rest of the characters noted under *K. thoracata*, are precisely the same in the present species. Two individuals exactly similar, except in the number of anal rays, occurred together at Pinang in June 1844.

Genus ALAUSA (ALOSA, *Cuvier* 1817) *Valenciennes* 1847. Small deciduous teeth in the jaws; all other parts of the mouth toothless.

(3850) *Alausa toli*, Cuv. and Val.

Syn. Alausa toli, Cuv. and Val. XX. 435.
Ikan truboh or trubu of the Malays.

Adult. Head above, back and upper third of the sides light greenish grey or lead-coloured; the scales strongly iridescent silvery; their margins dotted with black; rest of the sides, abdomen, cheeks and opercles strongly iridescent silvery; dorsal pale lead-coloured, in some individuals sparingly dotted with black; caudal scaly, pale silvery; upper lower and posterior margin minutely dotted with black; rest of the fins white. Iris mother-of-pearl, orbital margin blackish, or: head and body, instead of silvery, shining reddish yellow brass coloured; fins pale reddish yellow. Iris brass coloured. *Young.* Like the adult, but with a more or less distant blackish spot behind the upper part of the gill-opening and an indistinct vertical blackish spot at the root of five central rays of the caudal; upper half of dorsal closely dotted, so as to appear blackish. D 18, C 19$\frac{5}{5}$, A 19, V 8, P 15 or 16, Br, VI. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Borneo, Java, Sumatra, Pondicherry, River Cavery, Bombay. Total length: 1 ft. 6 inch. The length of the head is contained 4$\frac{5}{6}$ times in the total; the diameter of the eye is $\frac{1}{6}$ of the length of the head; it occupies the upper third of the head; the distance from the muzzle is $\frac{1}{4}$ of the length of the head; the distance across the arched forehead is 1$\frac{2}{3}$ diameter. The thick adipose fold covering the eye has a vertically elliptical aperture over the pupil. The first dorsal ray is excessively short and situated the length of one diameter of the eye behind the anterior third of the total length. The fourth and fifth are the longest, 2$\frac{1}{3}$ in the greatest vertical diameter of the body, which is contained 3$\frac{1}{2}$ to 2$\frac{2}{3}$ times in the total length. The upper margin of the fin is falciform; the posterior ray a little elongated; the extent of the base is $\frac{1}{2}$ of the length of the head. The eleventh ray is exactly in the centre between the muzzle and the middle of the root of the caudal. The latter is deeply cleft; the lower lobe, a little longer than the upper, is a little less than the greatest vertical diameter of the body. The extent of the base of the anal slightly exceeds that of the dorsal; the last ray is a little elongated; the first ray is situated at equal distance from the root of the caudal and the last ventral ray. The first ventral ray is situated in the centre between the muzzle and the root of the caudal, opposite the second fourth of the dorsal; [M. Valenciennes refers Russell No. CXCV. *Kelee*, to the young of the present species, but the ventral fins are placed very far backwards, opposite the posterior fourth of the base of the dorsal. If therfore the figure of Russell is correct, it represents a species different from *A. toli.*] the length of the fin is $\frac{1}{3}$ of the caudal; that of the elongated, triangular scale $\frac{2}{3}$ of the longest ray. The pectorals extend nearly to the ventral; their length is $\frac{3}{4}$ of the head; the elongated auxillary scale is $\frac{1}{2}$ of the length of the fin. The sides are covered by 15 longitudinal series of scales, of which there are 39 or 40 between the gill-opening and the caudal. By these characters it may readily be distinguished from a closely allied species; *Alausa ilisha*, (Buchan. Ham.) [Syn.: Russell CXCVIII.

Palasah.—*Clupanoden ilisha*, Buchan. Ham. 243, 382, Tab. XIX. Fig. 73 (*Young.*)—*Alosah palasah*, Cuv. R. A. II. 320 (1).—*Clupanodon ilisha*, Taylor: Gleanings of Science, II. 171.—*Alausa palasah*, Cuv. and Val. XX. 432.—*Alosa palasah*, Jerdon: Madras Journ. XV. 345. (Excl. Syn. *Clupea indica*, Gray).—The number of fin rays is: D 19, C 19/8, A 19 V 8, P 14, 15 or 16, Br. VI. It has 19 longitudinal series of scales, of which there are 47 to 49 between the gill-opening and the caudal. Buchanan Hamilton gives: D 20, A 21, probably owing to his having counted the last double rays as single. Sir John Richardson quotes, not without doubt, a specimen in the British Museum as *Alosa Palasah*, Russell 198 ? (Report 1845, 306). Forty scales form a longitudinal row, and there are fifteen rows in height "the pectorals reach nearly to the ventrals, which are attached before the middle of the dorsal." These characters are sufficient to prove the species to be distinct from Russell's *Palasah*, while they agree with *Alausa toli*, Cuv. and Val. But Sir J. Richardson counts; D 16, A 18, P 15, V 9.] Small individuals are at Pinang very numerous during all seasons; larger ones less so, although by no means scarce. Like *A. ilisha* in Bengal, the present species is by the English of the Straits Settlements denominated: *Shad* or *Sablefish*, and is equally valued for its flavour. Both are, however, somewhat oily, very rich and bony. *Alausa toli* is remarkable as forming in the Indian Archipelago a distinct and important branch of fishery, principally for the sake of its roe. It is the kind of "*Shad*" to which Mr. Crawfurd refers as frequenting the great river Siak in Sumatra, and of which the dried roe, of enormous size, constitutes an article of commerce. (Crawfurd: *Hist. Ind. Archipel.* III. 440.—Royle: *On the Production of Isinglass*, 76). A description of the fishing of this species is given by the late Mr. Moor in *Notices of the Indian Archipelago*, &c. p. 29. "At Bukit Batu, [opposite to, and a little to the southward of Malacca.] a place on the main of Sumatra within the Strait formed by the island of Bankalis, exists an extensive fishery well known in this part of the world. The fish which is the object of it is called in the Malayan language: *Trubu*. The fish itself is sufficiently known in all the neighbouring seas but found with a roe only here, [That is to say, in shoals, for it is plentiful at Pinang, Malacca and Singapore.] which makes it certain that it repairs to this favoured place for the purpose of spawning. The *Trubu*, about a cubit long, is taken in 3 and 4 fathoms water on a mud bank. About 300 boats are engaged at all seasons in the fishery with the exception of four days during dead neap tides. The roes are an article of trade seaways, and the dried fishes are sent into the interior of Sumatra. The Rajah of Siak draws a revenue from this fishery of 72,000 guilders yearly, receiving a certain duty upon the quantity taken. From the rate and amount of this duty it is ascertained that the quantity of fish caught yearly amounts to between fourteen and fifteen millions. It seems a little remarkable that the spirit of European monopoly never should have fastened upon so promising an object of gain. The fishery, from its peculiar nature, is probably quite inexhaustible, and might unquestionably be prodigiously improved by European skill and industry, and this too not only without detriment, but probably to the great improvement of the revenue of the native prince, as well as the essential benefit of the surrounding population." In the Malayan Markets the roe is called "*Telur ikan*," the fish-roe "par excellence." Like the preparation of fermented fish and shell-fish: "*Balachan*," it is largely used by the Malays and Chinese to season and make their food palatable and it is no less a favourite relish with Europeans. W. T. Lewis, Esq. Resident Counsellor, Pinang, who has observed the process of preparation in Sumatra, describes it as follows. The fresh roe is thoroughly salted, and next partially dried, so as to retain a slight moisture, in which state it is by hundreds closely placed in casks, and thus exported. In our Malayan Settlements the price is from 3 to 4 Spanish Dollars per hundred. The dealers there export considerable quantities to China, after having taken the precaution to repack the roes between layers of salt, and to sprinkle them with arrack. To dress them, they are soaked for about half an hour in water, and then fried. As the roe appears in commerce, it is of an elongated flat shape, measuring from 6 to 8 inches in length, about 2 in breadth, and 3/4 of an inch in depth, of a deep amber colour. The single eggs are larger than those of *A. illisha*.

(3851) *Alausa Champil*, (Cuv. and Val.)

(*Icon.*) Clupea champil, Gray: Ill. Ind. Zool. II. Pl. 91, Fig. 5 and 6.
Pellona champil, Cuv. and Val. XX. 324.

Head above, back and upper third of the side pale sea-green, sparingly dotted with black; rest of the body and head silvery with lilac reflections; from behind the upper part of the opercle to the caudal a pale longitudinal lilac band, the upper margin of which pale silvery; dorsal, anal and caudal yellowish white, the two first with a black dot at the root of each ray; caudal minutely dotted with black; rest of the fins hyaline. Iris silvery with lilac reflections. D 16, C 19/8, A 18, V 7, P 11, Br. VI. Inhabits *Sea of Pinang*. Total length: 3 1/8 inch. The length of the head is 1/5 of the total; the horizontal diameter of the orbit is a little less than 1/3 of the length of the head; the distance across the forehead equals the diameter. The jaws are nearly equal; the length of the upper slightly exceeds the diameter of the eye. There

are no teeth in any part of the mouth. The greatest vertical diameter of the body, in front of the dorsal fin, is contained 3⅓ times in the total length. The sides are covered by 11 longitudinal series of scales, of which there are about 42 between the gill-opening and the caudal. The abdominal line carries 29 fine species. The dorsal commences a little in front of the centre between the muzzle and the root of the caudal. the fifth, the longest ray, is ⅔ of the length of the head and equal to the extent of the base. The upper margin is straight; the last ray a little elongated. The caudal lobes are equal, ¼ of the total length. The anal commences a little in front of the posterior fourth of the distance between the muzzle and the root of the caudal; the length of the longest rays, the 4th, and 5th, is ½ of the 5th dorsal: the extent of the base slightly exceeds that of the dorsal. The first ventral rays is situated opposite the first dorsal ray, a little nearer the first pectoral than the first anal rays; the length of the fin is ½ of that of the head. The length of the pectorals is ¾ of the head. Two individuals of equal length occurred together at Pinang in October 1843. Both strikingly resemble a drawing of Buchanan Hamilton's duplicate series, marked in Buchanan's hand writing: "*Clupea champil, B.*" This drawing is evidently the orginal of the indifferent copy in the *Illustr. of Indian Zool.*, which is the foundation of *Pellona champil*, Cuv. and Val. It is one of the few drawings which Buchanan has omitted to describe in his work upon the fishes of the Ganges.

Genus ENGRAULIS, (*Cuvier* 1817) *Valenciennes* 1848. Mouth cleft far behind the eyes; muzzle projecting, pointed; ethmoid bone advancing in front of the jaws; intermaxillaries soldered to the maxillaries, hid beneath the muzzle; vomer narrow with a few teeth on the anterior part; palatals and pterygoids narrow, bristling with minute teeth, or rough; gill-opening very large; body rounded or compressed like a knife-blade; abdomen trenchant or toothed.

(3852) *Engraulis brownii*, (Gmelin).

Bunga ayer, or Badah of the Malays.

Head above light greenish grey, a large oval blackish spot occupying the posterior half: back pale sea-green or greenish grey; sides and abdomen transparent greenish buff, or grey with reflections of mother-of-pearl; from the upper third of the gill-opening to the root of the caudal a broad longitudinal silvery band; cheeks and opercles shining silvery, the latter above dotted with black; caudal pale yellow, dotted with black, rendering the posterior margin blackish; rest of the fins hyaline. Iris silvery, orbital margin blackish. D 14, 15 or 16, C 19⅓, A 20 or 21, V 7, P 15 or 16, Br. XI. Inhabits *Sea and estuaries of Malayan Peninsula and Islands*, China sea, New Zealand, Madura, Java, Sumatra, Bombay, Coromandel, Bay of Bengal, Gangetic estuaries, Isle of France, Australia, New York, Havanah, Jamaica, Vera Cruz, Martinique, Barbadoes, St. Christopher, Rio Janeiro. Total length: 6 inch. The head is ⅕ of the total length; the horizontal diameter of the eye is contained 3½ times in the length of the head; the distance across the forehead equals one diameter; the greatest vertical diameter, in front of the dorsal, is ⅕ less than the length of the head. The body is covered by 7 longitudinal series of deciduous scales, of which there are from 35 to 38 on the third series. On the anterior twelve scales of this series appears the lateral line which consists of a linear central tube, which disappears or becomes indistinct on the rest of the scales. The latter are diaphanous, rhomboidal, with their horizontal diameter ½ of the vertical. The dorsal commences nearly in the middle between the muzzle and the centre of the posterior margin of the caudal; the anal commences opposite the posterior third of the dorsal. The ventrals are situated in the middle between the pectorals and the anal. The caudal is deeply cleft; the length of each lobe equals that of the head. In the Straits of Malacca as in the mouths of the Ganges, this species is astoundingly numerous at all seasons. Two to three inches is the usual length, five to six are very rarely seen. In fine weather swarms may be seen swimming near the water's edge, and making very short leaps closely above the surface of the sea. As Russell observes they are highly valued for their delicate flavour when

fried. In Java, Sumatra and the Straits of Malacca, large quantities are preserved both for home consumption and exportation to China and India. The delicious condiment is famed under the denomination of "*Red-fish*," (*Ikan merah* of the Malays,) or "*Malacca fish*," and is used as a relish. The following mode of preparation, as practised at Bencoolen and Malacca, has been communicated by W. T. Lewis, Esq. Asst. Res. Counsellor, Pinang. After the heads have been removed, the fishes (those of middling size are preferred), are cleansed, salted (in the proportion of one to eight parts of fish), and deposited in flat glazed earthen vessels. In the latter they are for three days submitted to pressure by means of stones placed on thin boards or dried plantain leaves. The fishes are next freed from salt and saturated with vinegar of Cocoa Palm toddy, after which are added powdered ginger and black pepper (the latter mostly entire), and some brandy and powdered "Red rice." After having been kept for three days, a little more vinegar is added before placing the fishes in well closed jars or bottles. They should be kept four or five months before being used. The expense of a quart bottle of the condiment is about 30 Cents, the, selling price one Spanish Doller. "Red rice" is the variety of *Oryza sativa* called *glutinosa* (*pulut, orbras sepulut* of the Malays) steeped in an infusion of Cochineal. In the Straits Settlements red rice is imported from China, and sells at the rate of 10 Cents of a Dollar per lb. The Chinese settlers in the straits prepare a similar red condiment with slices of *Ploynemus indicus* and *P tetradactylus* and also prawns.

(SETIPINNA, *Swainson*, 1837.—TELARA *Val.* 1848.—*Anterior pectoral ray elongated filamentous*)

(3853) *Engraulis Breviceps*, Cantor. Head and body reddish golden or brass colour, back sparingly dotted with black; fins reddish yellow, like the body, but not metallic; anterior half of upper dorsal margin, and the posterior caudal margin broadly brimmed with black; posterior fifth of the anal margin equally so. Iris reddish golden. D 1/16, C 19$\frac{1}{3}$, A 63, V 7, P 13, Br, XVI—XVI. Inhabits *Sea of Pinang*. Total length: 9$\frac{4}{8}$ inch. The head is strikingly short; the distance from the muzzle to the upper part of the posterior margin of the opercle is contained 8$\frac{2}{3}$ times in the total, (measured to the occiput, it is $\frac{1}{1\frac{1}{3}}$ of the total.) The horizontal diameter of the eye is $\frac{1}{4}$ of the length of the head; the distance across the forehead is a little less than two diameters. The greatest vertical diameter of the body, in front of the dorsal, is $\frac{1}{4}$ of the total length. The dorsal commences in the centre between the muzzle and the root of the caudal; the first soft ray is preceded by a short strong spine. The anal commences in front of the dorsal, opposite the second third of the total; the extent of the base of the anal is 2$\frac{1}{3}$ in the total. The upper caudal lobe is truncated. The ventrals are situated in the centre between the first ray of the pectorals and the anal. The first pectoral ray is a little less than 2$\frac{2}{3}$ times in the total length; it does not reach the middle of the anal. The second pectoral ray slightly exceeds $\frac{1}{4}$ of the first. This species nearest approaches *E. telara*, (Buchan. Hamilton). A single individual was observed at Pinang in August 1844.

(3854) *Engraulis taty*, Cuv. and Val.

SYN. Engraulis taty, Cuv and Val XXI. 60.

Head above and back greyish green or greenish slate colour, sparingly dotted with black; sides above the lateral line pale silvery green; the rest, abdomen, cheeks and opercles silvery; dorsal, caudal and anal yellow; ventrals and pectorals hyaline; in some the posterior caudal margin blackish. Iris silvery, orbital half bluish black. D 1/14, C 19$\frac{2}{3}$ A 52 to 56, V 7 P 16, Br. XIII—XIII. Inhabits *Sea of Pinang, Malayan Peninsula*, Malabar, Pondicherry. Total length: 6 inch. Measured to the upper part of the posterior margin of the opercle, the length of the head is contained 6$\frac{2}{3}$ times in the total, (to the occiput it is 9$\frac{2}{3}$ in the total.) The horizontal diameter of the eye is $\frac{1}{4}$ of the length of the head; the distance across the forehead is 1$\frac{1}{3}$ diameter. The greatest vertical diameter of the body, in front of the dorsal, is 4$\frac{1}{3}$ in the total length. The dorsal commences a little in front of the middle between the muzzle and the root of the caudal. The anal commences opposite the centre of the dorsal; the extent of the base is 2$\frac{2}{3}$ in the total length. The ventrals are situated in the centre between the first pectoral and the fifth anal ray. The upper caudal lobe is truncated. The first pectoral ray is 1$\frac{4}{5}$ in the total length: it reaches to the posterior third of the anal; the second pectoral ray is 3$\frac{1}{2}$ in the length of the first. Single individuals occur at Pinang at all seasons, and are eaten either fresh or dried by the natives.

(THRISSA, *Rafin.* 1845.—*Maxillaries greatly elongated.*)

(3855) *Engraulis mystax*, (Bloch-Schneider).

SYN, Clupea mystax, Bl. Schn. 429, No. 14, Pl. 83.
Thryssa mystax, Cuv. R, A. II. 323 (3).
Thryssa mystax Richardson Report, 1845. 309 (*Excl. Syn. Clupea malabarica and Poorawah. Russell*, 189?)
Engraulis mystax, Cuv. & Val. XXI. 67.

Head above and back dark bluish green; lighter silvery on the sides above the lateral line; behind the upper part of the gill-opening a triangular spot, composed of horizontal, black, dotted lines, downwards increasing in length; rest of the sides and abdomen silvery white; cheeks and opercle silvery with golden reflections; dorsal and caudal whitish yellow, marginal half minutely dotted with black; rest of the fins whitish transparent. Iris silvery, orbital margin bluish black. D1/13, C 19$\frac{3}{5}$, A 37, 38 or 39, V 7, P 14, Br. XII.

Inhabits *Sea of Pinang, Matayan Peninsula, Singapore,* Bombay, Malabar, Coromandel, Gangetic estuaries. Total length: 8 inch. The length of the head is $\frac{1}{5}$ of the total. The horizontal diameter of the eye is $\frac{1}{4}$ of the length of the head; the distance across the forehead is $1\frac{1}{2}$ diamcter. The greatest vertical diameter, in front of the dorsal, is $\frac{1}{4}$ of the total length. The upper jaw extends beyond the root of the pectorals. The dorsal commences a little behind the centre of the distance between the muzzle and the root of the caudal fin. The caudal lobes are equal, pointed, and as long as the head. The anal commences opposite the posterior third of the dorsal; the extent of its base is contained about $3\frac{1}{2}$ times in the total length. The ventrals commence nearer the pectorals than the anal, their distance from the symphysis of the lower jaw is $2\frac{3}{4}$ in the total length. The pectorals are $\frac{1}{4}$ shorter than the head; placed in contact with the sides, their apex extends to the last ray of the ventrals. At Pinang single individuals occur at all seasons and are eaten by the natives. Sir John Richardson considers *Clupea malabarica,* Bloch. (Pl. 432.—Bl. Schn. p. 425) and *Poorawah,* Russell, CLXXXIX, to be identical with the present species. But according to the description of *Engraulis malabarica,* (Cuv. and Val. XXI. 63, Pl. 609) the upper jaw extends very little beyond the margin of the opercle, and does not extend as far as the pectoral, and the latter barely touch the root of the ventrals. The figure of *Poorawah* is scarcely correct enough, nor the description (Russell, p. 72,) sufficiently explicit to determine the species. Dr. Bleeker has described a new species under the inadmissible name of *Thryssa porava,* which he with doubt refers to *Poorawah,* Russell, CLXXXIX. (Bleeker: *Bijdrage tot Ichth. Faunavan Madura,* in: *Verh. Batav. Genoots.* XXII. p. 14.)

(3856) *Engraulis purava,* (Buchan, Hamilton.)

Syn. Russell CXC. Peddah Poorawah.
Clupea purava, Buchan. Hamilt 238, 382.
Thrissa (Pedda Poorawah) Cuv. R. A. II. 323 (3).
Thrissa megastoma, Swainson, II. 293.
Engraulis purawa, Cuv. and Val. XXI. 65.

Head above and back dark bluish green; lighter silvery above the lateral line; rest of the sides, abdomen, cheeks and opercles silvery; fins coloured like those of *E. mystax.* Iris silvery; orbital margin bluish black. D. 1/13, C $19\frac{3}{3}$, A 43, 45 or 46, V 7, P 14, Br. XII. Inhabits *Sea of Pinang,* Coromandel, Gangetic estuaries, Java, Madura. Total length: 8 inches. The length of the head is $\frac{1}{5}$ of the total. The horizontal diameter of the eye is contained $4\frac{1}{2}$ times in the length of the head, the distance across the forehead is $1\frac{1}{2}$ diameter. The greatest vertical diameter, in front of the dorsal slightly exceeds $\frac{1}{4}$ of the total length. The maxillaries are narrower and longer than in *E. hamiltoni,* where they reach to the root of the first pectoral ray; in the present species they reach to the root of the posterior pectoral ray. The dorsal commences a little in front of the centre between the muzzle and the root of the caudal; the anal commences in the centre of that space, opposite the middle of the dorsal. The extent of the base of the anal is $\frac{1}{3}$ of the total length. The caudal lobes are equal, pointed, and as long as the head. The pectorals are a little shorter. The ventrals are situated a little nearer the pectorals than the anal. At Pinang this species appears to be of uncommon occurrence.

Genus COILIA, (*Gray,* 1831.) *Cuv. and Val.* 1848. [*Zool. Misc.* 9.—Mr. Gray's characters are: "Body tapering, compressed; dorsal fin short, over the ventrals; anal and caudal fin united; pectoral fins small; rays five; three upper long and free; rest of the characters like *Thrissa.*"] (Trichosoma, Trichosomus, *Swainson,* 1839.—Chæfomus, *McClelland,* 1843.) Gape wide; gill-opening very open; muzzle projecting, supported by the ethmoid bone; upper maxillaries free, projecting beyond the opercle, and in some species reaching the root of pectorals; dorsal placed on the anterior part of the back; body elongated, compressed, tapering to a pointed tail; anal joining the caudal, elongated, low, but in one species tail shortened and caudal widened, rounded; above the pectoral two groups of filaments, parting from a common base; in general characters like *Engraulis* (*Thrissa*), but the anterior pharyngeals are more distinctly, though minutely, toothed.

(3857) *Coilia reynaldi.* Cuv. and Val.

Syn. Coilia reynaldi, Cuv. and Val. XXI. 81. (*Young*).

Adult. Pale golden throughout; head above and back sparingly dotted with black; from the middle of the gill-opening towards the tail a series of distant rounded spots of shining or burnished gold; in some individuals a second shorter series from the root of the pectorals to opposite the anterior third of the anal; fins reddish yellow; upper half of dorsal sparingly dotted with black, caudal and margin of the anal blackish. Iris golden, orbital half black; pupil circular, but the aperture of the adipose orbital membrane horizontally elliptic.

D $\frac{\text{IV}}{1/15}$, C 11, A 107, to 116, V 7, P—, Br. X. 11

Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore,* Rangoon. Total length: 7 inch. The length of the head is $\frac{1}{4}$ of the body, the caudal not included, or $6\frac{1}{2}$ in the total. The horizontal diameter of the eye is $\frac{1}{4}$ of the length of the head; the distance across the forehead is

1½ diameter. The upper maxillaries reach but halfway between the angle of the lower jaw and the root of the pectorals. The greatest vertical diameter, in front of the dorsal, is contained from 5½ to 5⅔ times in the total length. The dorsal, preceded by a short, strong spine, commences a little in front of the second fourth of the total length; the first divided ray (the fifth of the fin,) terminates in a filaments, which, however, from its slenderness is frequently broken. The ventrals are situated opposite the commencement of the dorsal, a little nearer the pectorals than the anal. The latter commences a little behind the dorsal, at the second third of the total length. The extent of the base of the anal is 1¾ in the total length, in which the distance from the muzzle is 2⅔. The four pectoral filaments are contained 3½ times in the total length and reach a little behind the commencement of the anal; the second ray is divided in two, the other three are simple. The length of the pectoral rays does not exceed ⅔ of the head. The caudal is pointed. At Pinang single individuals occur at all seasons, and like the rest of the *Clupeoidæ*, are eaten by the natives either fresh or dried.

Genus CHATOESSUS, *Cuvier*, 1829. Mouth small, without teeth; muzzle projecting; on the upper jaw a notch and a corresponding tubercle on the lower; the superior combs of first branchial arches unite with those of the opposite side, forming a pennated point under the palate; body short, deep, oval; in some species the posterior dorsal ray elongated.

(3858) *Chatoessus chacunda*, (Buchan. Ham.)

Syn. Clupanodon chacunda, Buchan. Ham., 246, 383.
Chatoessus chacunda, Cuv. and Val. XXI. 111.

Head above and back sea-green, minutely dotted with black; sides and abdomen silvery or pale golden; the centre of the scales of the upper third of the sides minutely dotted with black, forming five very pale blackish longitudinal lines; behind the upper part of the opercle a large black spot; cheeks and opercles golden; caudal yellow, sparingly dotted with black; rest of the fins hyaline whitish; dorsal dotted with black. Iris golden dotted with black. D 19, C 19¼, A 20, V 7, P 15, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula,* Moluccas, Java, Malabar, Gangetic estuaries. Total length: 6 inch. The length of the head is contained 4⅔ times in the total. The horizontal diameter of the eye is ¼ of the length of the head; the distance across the forehead slightly exceeds one diameter. The greatest vertical diameter, in front of the dorsal, is 2⅔ in the total length. The body is covered by 13 longitudinal series of scales, the horizontal diameter of which is about ½ of the vertical. A series between the gill-opening and the caudal contains from 36 to 39 scales. The dorsal occupies the last of the anterior half of the total length; the fourth ray, the longest, equals the extent of the base, which is ⅔ of the head; the last ray is ½ of the fourth. The caudal is deeply cleft; the posterior margin of each lobe is arched; the length is 3½ in the total. The first ray of the anal is placed at equal distance from the first ventral and the root of the caudal; the fin is very low; its extent equals that of the dorsal. The ventrals are placed opposite the middle of the dorsal. The pectorals are ¾ of the length of the head. Single individuals occur, but rarely, at Pinang.

SUBORDER PHYSOSTOMI APODES.

Fam. MURÆNOIDÆ.

Genus CONGER, *Cuvier*, 1817. (Muræne-sox, *McClelland*, 1843.) ["*Absence of tubular nostrils*" is given as a character distinguishing *Muræneso*x from *Conger*. The character, however, is incorrect, as in all the supposed species of Mr. McClelland the anterior apertures of the nostrils are provided with a tube, which is very distinct in the living fish.] The dorsal commences very near, or even above the pectorals; in all species known the upper jaw is the longer.

(3859) *Conger talabon*, Cuvier.

Syn. Russel, XXXVIII. Tala Bon.
Conger (Muræna) talabon, Cuv. R. A. 350. (4).
Muræenesox lanceolata, McClelland, Calc. Journ. Nat. Hist. IV. 409.
Muræenesox exodon, McClelland, ibid.
Muræenesox serradentata, (Russell, XXXVIII.) McClelland, ibid.

Muræenesox serradentata, McClelland, ibid; 210.
Conger talabon, Bleeker: Verh. Batav. Gen. XXII. 6.

Head above, back and sides above the lateral line golden greenish- or brownish-olive, minutely dotted with black; upper lip, cheeks, opercles and lower half of the sides lighter golden olive; under lip, throat and abdomen milk-white; dorsal, caudal and posterior half of anal pale olive, transparent, minutely dotted and edged with black; anterior half of anal transparent white; pectorals transparent yellowish. Iris golden. Young individuals, frequenting estuaries, are of darker, less golden colours.

D 238 to 286,
C 9 to 11, } P 16, Br. XV.
A 151 to 129,
398 to 426

Inhabits *Sea and estuaries of Malayan Peninsula and Islands*, Coromandel, Tenasserim, Coast of Arracan, Bay of Bengal, estuaries of the Ganges, Sumatra, Java, Madura. Total length: 7 ft. 5 inch. The general form of the body is cylindrical, the anterior half slightly compressed, the posterior more so and tapering; the head is elongated conical, terminating in a narrow rounded muzzle near which in the upper jaw appears a wide notch, which receives the long conical teeth near the symphysis of the lower jaw. The length of the head, measured to the gill-opening, is $\frac{1}{6}$ of the body, not including the caudal, which latter varies from $\frac{1}{5}$ to $\frac{1}{7}$ of the length of the head. The distance from the muzzle to the anterior margin of the orbit varies from $3\frac{1}{3}$ times in to $\frac{1}{4}$ of the length of the head. The distance across the notch of the upper jaw is $\frac{1}{2}$ of the horizontal diameter of the orbit; between the anterior margin of the orbit it is $\frac{3}{4}$, between the posterior margins, it equals the horizontal diameter of the orbit. The latter is $\frac{1}{3}$, or a little less than $\frac{1}{3}$ of the distance from the muzzle to the anterior margin of the orbit. [In the larger, upper figure of the head in *Calc. Journ. of Nat. Hist.* V. Pl. VIII. Fig. 4, the eye is represented too small, and is placed too far back; in the smaller figure the eye is correctly placed, but the gill-opening is much too near the angle of the mouth. These disproportions materially affect the position of the dorsal and pectoral fins in the figure.] The latter margin is situated in front of the centre of the distance between the muzzle and the angle of the mouth, which distance is a little less than $\frac{1}{2}$ of the length of the head to the gill-opening. The anterior aperture of the nostrils is oval, provided with a short, yet very distinct tube; it is situated immediately above the lip, at the termination of the notch, a little in front of the centre between the muzzle and the anterior margin of the orbit. The posterior aperture is linear, or more elongated oval than the anterior, with the margin slightly raised, but not tubular; it opens a little in front of the eye at a distance from the anterior aperture equal to that of the latter from the muzzle. On each side of the crown of the head, a little farther back than the angle of the mouth, appears a transversal series of 8 to 10 pores; from the middle of each series proceeds forwards another shorter, longitudinal one, consisting of 3 to 5 pores. The distance from the muzzle to the angle of the mouth is one longitudinal diameter of the eye less than one half of the length of the head. The lips are thin, membranous, and closely adhering to the jaws. In the upper jaw appear three very close series of small conical teeth with the apex compressed and trenchant. The external series is excessively minute, and extends from the angle of the mouth to beneath the middle of the eye; the teeth of the second are about double the size of the former, with which they are in close contact, but they extend farther forwards to between the nasal apertures, where they coalesce with the external series of the teeth of the vomer; the third, internal, series consists of excessively minute conical teeth, distant among themselves and a little removed from the second series; they extend as far as the external series. Immediately in front of the notch the muzzle forms a small round space, the margin of which is armed with 4, 5, or 6 distant conical teeth, which are about $\frac{1}{3}$ of the diameter of the eye. From the middle of the muzzle commences a short single series of 6 or 7 small conical teeth; which, as they continue along the middle of the vomer, become distant, much longer, compressed towards the apex and with trenchant margins. The number of these teeth varies with age from 7 to 15, of which the longest are about $\frac{1}{2}$ of the diameter of the eye. In young individuals the two or three posterior ones are much compressed and tricuspidate. From the first long tooth commences a single close series of teeth which continue on each side of the vomer, but join each other a little behind the central series, which terminates between the eyes. The marginal teeth of the vomer are a little larger than the middle series of the jaw which they resemble in form. The lower jaw is much shorter than the upper: the symphysis is widened into a small rounded disk, on each side of which appear two or three long, distant, conical teeth, situated within the external series. The latter consists of much smaller outwards directed, distant, conical teeth, which beneath the eye decrease and become much closer. The middle series, headed by the longer ones behind the symphysis, consists of close, erect, conical teeth, with compressed trenchant apex. From beneath the eye the interval between the external and middle series is filled by a short series of minute conical teeth. The third internal series is also minute, and extends from the angle of the mouth to a little in front of the posterior half of the jaw. The tongue is small, elongated, and tied to the floor of the mouth; it extends to a little in front of the posterior third of the mouth. The vertical diameter at the occiput equals the distance from the muzzle to the posterior nasal aperture, or it is contained from $4\frac{1}{2}$ to 5 times in the distance from the muzzle to the gill-opening. The greatest vertical diameter of the body is $\frac{1}{3}$ of the distance from the muzzle to the gill-opening; the smallest, in front of the caudal, is $\frac{1}{4}$ of the latter. The lateral line commences from the side of the occiput, gently declining towards the end of the anterior fourth of the body, from whence it continues a little above the middle of the side straight to the caudal. It is composed of a series of tubes placed in pairs one above the other, none exceeding in length $\frac{1}{2}$ the diameter of the eye. Each lower tube sends two branches

obliquely downwards, and between these branches appears a pore. The dorsal commences a little in front of the gill-opening, at a distance from the base of the upper pectoral ray of $\frac{1}{8}$ of the length of that fin. The dorsal and anal rays are undivided. All the fins present the peculiarity of having double rays; they appear to be single, but are composed of two distinct ones placed transversely, and kept by the fin-membrane so closely in contact, that each pair can act like a single ray. The caudal is closely united with the dorsal and anal, from both of which it may be distinguished by its much slenderer, branched, rays; their length either equals or slightly exceeds that of the dorsal rays. The anus is situated in front of the middle, either at, or a little behind the end of the fifth-twelfth of the total length. The anal fin commences immediately behind the vent; the rays are $\frac{2}{3}$ of those of the dorsal. The pectorals are elongated, with branched rays; their length equals the distance from the muzzle to the posterior margin of the orbit. The skin is smooth and naked. The description and figure of Russell are sufficient, easily to identify the species, which Mr. McClelland has renamed *Muræsox serradentata* and described as having serrated teeth on the vomer. This error would appear to originate in a singular misinterpretation. Russell describes the jaws: "in both there are long crooked teeth in front, with a regular row of straight teeth in the upper jaw, *which is* rough on both sides like a file." Russell could not have chosen a more correct simile of the roughness of the upper jaw of the young individual he had before him, but he says nothing of the teeth being serrated. *Muræsox exodentata*, McClelland, differs in no one character from *serradentata*, but the description is inaccurate as far as concerns the dentition, the anterior aperture of the nostrils, and the lateral line. Nor is *Muræsox lanceolata*, McClelland, different from either of the preceding, but the dentition and anterior nasal apertures are incorrectly described. *Conger talabon* is in the Straits of Malacca, numerous at all seasons, but individuals exceeding 3 to 4 feet are less common. The Malayan denominations of *ikan ular*, (i. e. fish-snake,) and *malang* are indiscriminately applied to eels, all kinds of which are eaten by the natives. The heart is situated immediately behind the gill-openings. The œsophagus extends as far behind the latter as the distance from the muzzle to the angle of the mouth. The stomach is a narrow cylinder about $\frac{1}{5}$ of the total length, extending to the anus; the coats are thick and firm, with longitudinal folds on the internal surface. The intestine is a simple cylindrical canal, thinner than the stomach; the posterior part is a little tortuous, which makes it a little longer than the stomach. The liver is bilobate, very short, of a brownish yellow colour; it commences from the apex of the heart, and adhering to œsophagus, it terminates at the origin of duodenum, where the short, straight cystic duct enters. The gall-bladder is small, oval, of a greenish white colour. The spleen is short, linear, adhering to duodenum, of a pale crimson colour. The air-vessel is elongated, spindle-shaped, not exceeding the diameter of the stomach; it commences above the cardia, follows the stomach, but extends behind the anus in a cavity in the tail; the length is about $\frac{1}{3}$ of the total; the coats are very thin, transparent silvery white.

Colours exactly like those of *C. talabon*.

D 238 to 245,
C 9 to 11, } P 15 to 18, Br. XX.
A 198 to 211,

445 to 467.

Inhabits *Sea and estuaries of Malayan Peninsula and Islands*, Japan, Chusan, Ningpo, Canton, Coromandel, Bay of Bengal, Tenasserim, Gangetic estuaries. Total length: 5 ft. The general form resembles that of *C. talabon*, but it is less slender, the muzzle less elongated, the eye larger, the teeth of the vomer and some of those of the lower jaw are tricuspidate; the dorsal and anal extend farther forwards; the pectorals and caudal are shorter, and the branchiostegous rays more numerous. The length of the head, from the muzzle to the gill-opening, is contained from $6\frac{1}{2}$ to $6\frac{1}{3}$ times in the total length. The distance from the muzzle to the anterior orbital margin is $\frac{1}{4}$ of the length of the head. The distance across the notch of the upper jaw equals the horizontal diameter of the eye, which is $\frac{1}{3}$ of the length of the muzzle; the distance between the anterior margins of the orbits is $1\frac{1}{4}$, between the posterior margins it is two diameters. The eye occupies the third-eighth of the head; the anterior margin of the orbit is situated at the posterior third of the distance from the muzzle to the angle of the mouth; the length of the mouth is contained $2\frac{1}{2}$ to $2\frac{1}{3}$ times in that of the head. The anterior, tubular, aperture of the

nostril opens at the end of the anterior third of the distance between the muzzle and the eye; the posterior occupies the commencement of the posterior third of that distance. The pores of the crown of the head are very indistinct. The general distribution of the teeth resembles that of *C. talabon*, but the teeth themselves present the following differences. Those of the mesial line of the vomer are compressed, with trenchant edges and tricuspidate; the central cusp is much larger than that at the root of the anterior and posterior margin. They resemble the teeth of certain sharks, and are placed at intervals; more than from 5 to 7 are seldom present. Of the three longest, in the middle of the vomer, none exceeds $\frac{1}{2}$ of the horizontal diameter of the eye; their breadth is $\frac{1}{2}$ the length. Of the three single series on each branch of the lower jaw the external and internal are equally minute and close. The middle series are much larger, tricuspidate, compressed and trenchant. The tongue resembles that of *talabon*, but the upper lid between the notch and the eye is fleshy, and covered with minute pointed lobes of the skin, which resemble velvety teeth; otherwise the lips present no difference. The vertical diameter at the occiput equals the distance from the muzzle to the eye, $\frac{1}{4}$ of the length of the head, of which the greatest diameter of the body is $\frac{1}{5}$. The tail is more tapering than in *talabon* so that the vertical diameter in front of the caudal is from $\frac{1}{10}$ to $\frac{1}{12}$ of the greatest diameter of the body. All the fin-rays are double. The pectorals are rounded; their length is $\frac{1}{4}$ of the head. The dorsal commences more in front of the gill-opening than in *talabon*, at a distance from the root of the upper pectoral ray of from $\frac{1}{2}$ to $\frac{2}{3}$ of the length of that fin. The longest dorsal rays are $\frac{1}{3}$ to $\frac{1}{2}$ of the greatest vertical diameter of the body. The caudal is so closely joined to the dorsal and anal, that the rays cannot be distinguished but by their position; their length is about $\frac{1}{2}$ of the longest dorsal. The anus opens at, or a little in front of the end of the second fifth of the total length. The fin commences immediately behind the anus; the longest rays scarcely exceed $\frac{1}{2}$ of the dorsal ones. The description of *Muræna bagio*, a drawing in Buchanan's duplicate series thus marked in his own hand-writing, and comparison of individuals from the Straits of Malacca and Calcutta prove the identity of the species. Those from the latter locality are of a darker olive colour, and not golden like those frequenting the sea. Buchanan has observed the strong resemblance of *bagio* and *Talwo Paum*, Russell, No. XXXVI. p. 25. In the not very explicit description of the latter, the upper jaw is characterised as being "somewhat shorter than the lower," which, if correct, militates against the identity of the two. *Muræsesox tricuspidata*, McClelland, offers no character different from *bagio*, but the dentition is incorrectly described. Such is also the case with *Muræsesox bengalensis*, McClelland. Of Buchanan's drawing of *Muræna bagio*, (*Muræsesox hamiltonii*, McClelland,) an incorrect copy is given in *Calc. Journ. of Nat. Hist.* Pl. VIII. 3. [The drawing was first inscribed "*Opisuroides*," afterwards altered by Buchanan himself to "*Muræsophis bagi*." It represents the fish stretched, and thus correctly gives the proportions. In Mr. McClelland's copy above quoted the fish is doubled, by which some of the proportions are lost, and the apertures of the nostrils are incorrectly copied.] This species Mr. McClelland observes he never met; yet the short description of *Muræsesox bengalensis*, McClelland, differs from the former in no essential character, except in the number of fin rays, which comparison proves is liable to considerable individual variations in the present species as well as in *talabon*. Buchanan himself is doubtful about the correctness of his number of rays of *bagio*. *Conger hamo*, Temminck et Schlegel, from Japan, only differs in the colours of the body which above is greyish brown, and in having the iris silvery. In the Straits of Malacca young individuals of *Conger bagio* are as plentiful as *talabon*. Both are fierce and of voracious habits, preying upon fishes and crustacea, and their bite is dreaded by the fishermen. The anatomy of this species offers some slight differences from *C. talabon*. The heart is situated nearer the head, immediately above the gill-openings. The œsophagus extends but as far behind the latter as half the distance from the muzzle to the angle of the mouth. The cylindrical stomach extends to the anus and is $\frac{1}{5}$ of the total length, of which the intestine is $\frac{1}{3}$. The right lobe of the liver is a little larger than the left. The pearl-coloured coats of the spindle-shaped air-vessel are thick, not transparent; the length is contained a little more than $2\frac{1}{2}$ times in the total.

Genus OPHIURUS, *Lacepede*, 1800. (Leptognathus, [*Classif. of Fishes*, I. 221, Fig. 42; II. 334.] *Swainson*, 1838.—Ophithorax, [(Scr. Ophiothorax.) *Calcutta Journal Nat. Hist.* V. 173 and 212.] *McClelland*, 1844). Dorsal and anal terminating before reaching the end of the tail, which is without fins, terminating like a puncheon; posterior aperture of the nostril opens on the margin of the upper lip.

A. *With globular teeth.*

(3861) *Ophiurus baccidens*, Cantor.
Plate V. Fig 1. (Natural size.)

Head above and back dull greenish olive; lighter on the sides, dotted with brown; throat and abdomen greenish- or bluish white; fins pale olive-grey or white, dotted with brown; dorsal edged with black. Iris golden greenish olive; pupil horizontally lanceolate. D 259 to 271, A 167 to 180, P 17, Br. XXXIV. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*. Total

length: 3 feet. The general form is thick, heavy; the head broad, the muzzle short, depressed, pointed; the body cylindrical; the tail gradually compressed and tapering to a short point. The length of the head, from the muzzle to the gill-opening, is contained from 8½ to 8⅔ times in the total. The distance from the muzzle to the anterior orbital margin is ⅛ of to 6½ times in the length of the head; the eye, bordering upon the forehead and the lip, occupies the third-eleventh of the length of the head; the distance between the anterior orbital margins is 1⅓, between the posterior ones it is 2 horizontal diameters of the eye. The posterior orbital margin is situated a little in front of the angle of the mouth, the distance between which and the muzzle is contained 3⅓ times in the length of the head. On each side of the crown of the head, from between the eyes to the muzzle, appears a series of four distant pores; behind each eye are three such vertically placed on each side, on the occiput two, along each side of the upper lip five or six, and beneath each branch of the lower jaw six such pores. The upper lip is fleshy, and lax, and gives the symphysis a more rounded outline than it really has. On each side of the symphysis opens the anterior nasal aperture through a voluminous tube. The posterior apertures perforate the lower surface of the lip; they are linear, terminating obliquely outwards beneath the anterior orbital margin, and have a valve on the external margin: their length is ½ of the diameter of the eye. About midway between the anterior and posterior apertures appears a small pointed lobulet, and a smaller one immediately behind the posterior aperture. The middle of the lower surface of the point of the muzzle is occupied by a rounded cluster, (nearly of the size of the eye,) of globular teeth, like minute pearls, of which two or three in the centre are a little larger than the rest. A little behind this cluster commence the teeth of the middle line of the palate which resemble the former, and are arranged in the shape of a short dagger. On each side of the jaw is an elongated, pointed and backwards diverging band of teeth. They commence with a narrow interval from the handle of the dagger and are all globular, except a single series of minute pointed teeth along the internal margin of each band. The lower jaw is one diameter of the eye shorter than the upper, leaving uncovered the point of the muzzle with its teeth and the nasal tubes. The teeth resemble those of the upper jaw with a similar internal series of pointed ones; the band of each branch is separated by a narrow interval on the symphysis. The tongue is oval and tied to the floor of the cavity extending but little in front of the posterior third of the mouth. The vertical diameter at the occiput is ½, at the anus 8½, at the termination of the dorsal and anal $\frac{1}{16}$ of the length of the head. All the fin rays are double; those of the dorsal and anal undivided. The rounded pectorals are placed obliquely a little behind the gill-opening; their length is ⅓ of the head; the distance from the muzzle to the root of the upper ray is contained 8½ times in the total length. The dorsal commences above the end of the anterior third of the pectorals and terminates rather abruptly at a distance from the compressed point of the tail equal to the diameter of the eye; the largest rays do not exceed the distance from the muzzle to the anterior orbital margin. The anus opens two diameters of the eye behind the termination of the second fifth of the total length. The fin commences immediately behind the anus, and terminates opposite the dorsal which it resembles in length. The lateral line commences from the side of the occiput, occupying the upper third of the side till it reaches the anus, from whence it continues in the middle to the point of the tail. Beneath it is accompanied by a series of pores, one diameter of the eye distant from each other. This species is numerous at all seasons. In external appearance it resembles *O. cancrivorus*, Richardson (*Zool. Erebus and Terror, Fishes*. Pl. 50, Fig. 6,) but the latter is more slender, the teeth of the jaw and palate appear in front to coalesce; there are no pores behind the eyes, but four along each branch of the lower jaw. The heart is placed immediately behind the gill-openings. The apex of the heart is clasped by the bifid anterior extremity of the broad, thick, single-lobed liver which extends to cardia and pylorus; it is of a brownish lake colour; the small gall-bladder is almost entirely imbedded in the substance of the liver. Both cardia and pylorus are situated at the end of the second eleventh of the total length. The cylindrical elongated stomach extends to within a short distance from the anus; the anterior third portion is thick, muscular, with internal longitudinal folds; the rest of the sac is membranous, without folds, and widened at the transition. The duodenum is wider than the rest of the canal, the length of which is ⅓ of the total. The pale crimson spleen is short, linear, adhering to the duodenum. The silvery-white air-vessel is linear, spindle-shaped; it commences a little in front of the posterior half of the distance between the muzzle and anus, at the origin of the membranous portion of the stomach and extends but a little into the cavity of the tail. The latter terminates as far behind the anus as the anterior half of the total length. The cavity contains the bluish grey kidneys, which extend but a little in front of the anus, and the ovaries, which farther occupy nearly the whole length of the abdominal cavity, and extend to halfway between the pylorus and the heart. The oval are very minute, of a whitish yellow colour.

(3862) *Ophiurus boro*, Buchanan Hamilton. Plate V. Fig. 2, (Nat. size.)

Syn. Ophisurus boro, Buchan. 20, 363.

(*Icon.*) Ophisurus boro, Gray: Ill. Ind. Zool, I. Pl. 95. Fig. 1.
Ophisurus boro McClelland: Calc. Journ Nat. Hist. V. 185 211.
Ophisurus boro, Richardson, Report, 1845, 313.

Ground-colour whitish yellow; upper half of head and body, so closely dotted with black, as to produce a general blackish appearance; dorsal pale olive white, dotted and edged with black; anal white; pectorals pale yellowish olive dotted with black; abdomen white. Iris pale golden, dotted with black. D 315 to 328, A 205 to 244, P 13, Br. XXXI. [These are the greatest variations in individuals examined at Pinang and in Calcutta. Buchanan counts: "A 270?"] Inhabits *Sea of Pinang*, Estuaries of the Ganges. Total length: 2 feet $2\frac{4}{5}$ inch. The greater part of the body is cylindrical, of nearly equal diameter, but the posterior seventh is gradually compressed and tapering. The length of the head to the gill-opening varies from $9\frac{1}{2}$ to $10\frac{2}{5}$ times in the total; it appears constantly to be $\frac{1}{4}$ of the distance from the muzzle to anus. The latter is situated either at or a little in front of the end of the second-fifth of the total length. The horizontal diameter of the eye is $\frac{1}{17}$ of the length of the head. The distance from the muzzle to the anterior orbital margin equals two diameters, or the distance between the eyes across the forehead. The distance from the muzzle to the angle of the mouth is contained $3\frac{1}{2}$ times in the length of the head; the lower jaw is one diameter of the eye shorter than the upper. The nostrils, their lobulets, and the tongue resemble those organs of *O. baccidens*. Beneath the muzzle is a small rounded spot with globular teeth, some of which are larger than the rest, which are continued on an elongated pointed band along the mesial line of the palate. The broadest part of this band contains 4 to 5 series. The teeth of the upper jaw are somewhat smaller than the palatal ones, with which they do not coalesce; the broadest, anterior, portion contains about five series, of which the internal one consists of minute pointed teeth. The bands of the lower jaw have a linear interval over the symphysis, the broadest portion; the teeth resemble those of the upper jaw, but there appear no series of pointed teeth. From between the eyes, on each side of the crown of the head, proceed a series of four distant pores to the muzzle; behind each eye appear three, and there are other series along both jaws and across the occiput. The lateral line resembles in its course that of *O. baccidens*, but the line itself and the pores are more minute. The vertical diameter at the occiput is contained $3\frac{4}{5}$ times in the head; the greatest one of the body is $\frac{1}{3}$ of the length of the head; that between the termination of the dorsal and anal is 2 diameters of the eye, and constitutes the base of an equilateral triangle formed by the compressed tip of the tail. The dorsal, which is partly concealed in a deep groove of the back, commences at a little distance behind the apex of the pectorals, the distance from the root of the upper pectoral ray to the first dorsal varies from $\frac{1}{3}$ of to $2\frac{1}{3}$ times in the distance from the muzzle to the dorsal. The rays of the dorsal and anal fins are $\frac{3}{4}$ of the length of the pectorals which measure $\frac{1}{5}$ of the head. Single individuals are taken along the coasts of Pinang at irregular intervals.

B. With pointed teeth.

(3863) *Ophiurus grandoculis*, Cantor. Plate V. Fig. 3, (Magnified.) Ground-colour of head back and sides yellowish white, minutely and closely vermiculated with brown, and dotted with black, so as to produce a general brownish appearance, lighter on the sides; abdomen white; fins greyish white; minutely dotted with black; dorsal and posterior half of anal edged with black. Iris pale golden, dotted with black. D 251 to 258, A 152 to 167, P 15, Br. XXXI. Inhabits *Sea of Pinang*. Total length: 1 foot $6\frac{4}{5}$ inch. The head is elongated with a conical, somewhat bluntly pointed muzzle, the general form of the body resembles that of *O. boro*. The length of the head to the gill-opening is contained $11\frac{1}{2}$ to $11\frac{3}{4}$ times in the total, but $4\frac{1}{2}$ to $4\frac{2}{3}$ times in the distance from the muzzle to the anus. The eye is comparatively large, its horizontal diameter varying from $\frac{1}{11}$ to $\frac{1}{13}$ of the length of the head; the distance from the muzzle to the eye is two diameters; the eye itself occupies nearly the whole space between the lip and the profile; the distance across the forehead equals one diameter. The distance from the muzzle to the angle of the mouth is contained $3\frac{1}{2}$ times in the length of the head; the lower jaw is half a diameter of the eye shorter than the upper. The nostrils, labulets, pores of the head and of the lateral line, as well as the latter itself, resemble those of *O. boro*. The middle of the tip of the upper jaw has two close series of subulate teeth; in the young each series consists of 3 to 4, but one half of them appear to vanish with age, when those remaining become stronger and blunter. At a short distance behind these commence the double series of teeth of the mesial line of the palate; those of the anterior half are longer than the rest, and become subulate with age; on the posterior half the teeth are much smaller, and placed three deep. The teeth of the jaw commence on each side of those of the mesial line without coalescing with them; they are placed in a single series, are small, pointed or subulate. Those of the lower jaw are also in a single series, subulate, and they decrease from the symphysis, on which there is a toothless interval between the series of both branches. The tongue is small, elongated and tied to the floor of the mouth, of

which it occupies the posterior third. The vertical diameter at the occiput is ⅓ of the greatest of the body is contained 2½ times in the length of the head, while that between the terminations of the dorsal and anal equals the diameter of the eye and forms the base of the triangular tip of the tail, each of the sides of which is two diameters of the eye. The dorsal commences above the posterior third of the pectorals. The distance from the root of the upper pectoral ray to the dorsal is 4⅔ to 5 times in that from the muzzle to the dorsal; the general length of the dorsal rays is contained 5⅓ times in the head; but immediately before the termination of the fin, the rays suddenly increase in length, and are but 4¼ times in the head. Such is also the case with the anal, which resembles the dorsal. The anus is situated a little in front of the end of the third-fifth of the total length. The pectorals are elongated, ⅓ of the length of the head. Single individuals occur at all seasons at Pinang. The present species bears a general resemblance to *O. hijala*, Buchanan Hamilton, but in the latter the dorsal commences at a short distance behind the pectorals. [Buchan. Ham. pp. 20, 356, Pl. V Fig. 5 SYN. *O. hyala*, Cuv. R. A. II. 351. (1)—*O. puncticulata*, Swainson, II. 334.—*O. rostratus*, McClelland, Calc. Journ. Nat. Hist. V. 184, 211.—*O. hyala*, McClelland, ibid. V. 184, 185.—*O. hijala*, McClelland, ibid, V. 211. —*O. minimus*, McClelland, ibid. V. 185, 212, Pl. X. Fig. 3.—*O. caudatus*, McClelland, ibid V. 185, 204, Pl. XII. Fig. 3.—*O. rostratus* Richardson: Report, 1845, 313.—*O. hijala*, Richardson, ibid. 314.—With regard to the nomenclature of Mr. McClelland, it is necessary to observe that the duplicate series of Buchanan Hamilton's drawings contains a figure of this eel, marked in Buchanan's handwriting. "*Ophisuris rostratus*," which is evidently the same as Pl. V. Fig. 5, *O. hijala*, (*Fishes of the Ganges.*) In publishing the figure and the description, Buchanan chose to alter his manuscript name "*rostratus*" to "*hijala*." It is this, by Buchanan himself *cancelled, manuscript name* "ROSTRATUS," which Mr. McClelland has introduced as if it were a species distinct from *hijala*, and of which he says: "I have not met with it, but it is closely allied to *Oph. minimus*, from which it only differs in having a square muzzle."—*O. minimus*, McClelland, is characterised as having "the distance from the point of the muzzle to the eyes equals to 1-5 of the distance from the eyes to the pectorals." But in Mr. McClelland's figure (Pl. X. Fig. 3,) the former distance is *one-third* of the latter, exactly as represented in the outline of *O. hijala*, Buchanan, (Pl. V. Fig. 5. *Fishes of the Ganges.*)—Of *O. minimus*, McClelland, it is farther said: "the distance from the muzzle to the branchial apertures, is equal to the distance from these to the commencement of the dorsal." In the figure, however, the former distance slightly, yet perceptibly, exceeds the latter, just as it is represented in the figures of *O. hijala*, Buchanan Hamilton. In *O. caudatus* McClelland, the distance from the base of the pectorals to the dorsal is described as equalling half the distance from the pectorals to the end of the muzzle. In Mr. McClelland's figure, however, the former distance is represented as contained 2⅔ times in the latter.

(3864) *Ophiurus breviceps*, Cantor. Plate V. Fig. 4, (Magnified.)

Head above and back greenish olive, lighter on the sides of the head and body, everywhere minutely dotted with black: throat and abdomen greenish white; dorsal greenish white, dotted and edged with black; pectorals and anal greenish white dotted with brown. Iris pale greenish golden, dotted with black.

D $\begin{cases} 480, \\ 448, \end{cases}$ A $\begin{cases} 276, \\ 298, \end{cases}$ P 13, Br. XXXI.

Inhabits *Sea of Pinang*. Total length: 2 ft. 2⅞ inch. The head is proportionally very short, elongated conical, terminating in a narrow truncated muzzle; the eye small; the body cylindrical, suddenly deepening behind the anus, and slowly tapering towards the small blunt point of the tail. The length of the head is $\frac{1}{18}$ or a little less, of the total and contained 5¾ times in the distance from the muzzle to the anus. The latter is situated either in the middle of the third-eighth or a little in front of its termination. The horizontal diameter of the small oval eye is contained 13½ times in the length of the head; the distance across the forehead is 1½ diameter; that from the muzzle to the eye 2½ such diameters. The distance from the muzzle to the angle of the mouth is contained 3½ times in the length of the head. The upper jaw is a little less than one diameter of the eye longer than the lower. The nostrils and their lobulets, the pores of the head and the lateral line resemble those of *O boro*. The very minute whitish pores beneath the lateral line are placed at a distance from each other of two diameters of the eye. On the mesial line of the tip of the upper jaw appear two series, each consisting of three small pointed recurvous teeth. At a short distance behind the latter commences the series of the mesial line of the palate; the anterior teeth are a little stronger than the rest, and placed three deep, then two, and posteriorly in a single series of excessively minute teeth. On each side of the mesial series commences a single one of fine, pointed teeth, which is the internal series of the jaw; behind the posterior aperture of the nostril commences an external series of similar teeth. Those of the lower jaw resemble the latter, but they are throughout placed in a double series, except over the symphysis which is naked. The small elongated tongue is tied to the floor of the mouth; it is placed unusually far forwards and nearly extends to the

anterior third of the cavity. The vertical diameter continues uniform from the occiput to the anus, varying in two individuals examined, from $3\frac{1}{2}$ times in, to $\frac{1}{4}$ of the length of the head, while their greatest diameters of the two anterior thirds of the tail vary from $\frac{1}{2}$ to $\frac{1}{3}$ of the head. The vertical diameter between the termination of the dorsal and anal is but two diameters of the eye, forming the base of the equilateral triangular point of the tail. The small pectorals are from $\frac{1}{3}$ of, to $3\frac{1}{2}$ times in the length of the head. The dorsal commences above the apex of the pectorals. Its distance from the root of the upper pectoral ray equals the length of the pectoral fin, and is $\frac{1}{4}$ of its distance from the muzzle. The length of the dorsal rays is but $\frac{1}{5}$ of the head. The anal rays are a little longer. Two individuals occurred together at Pinang in November 1844. Although there was a difference of but $2\frac{2}{8}$ inch in length, the longer was out of proportion, the thicker.

Genus DALOPHIS, (*Rafinesque* 1810) *Swainson*, 1839. [Swainson: *Classif.* I. 221; II. 335.] No pectoral fins; gill-openings placed very low, towards the sides of the throat; dorsal and anal terminating before they reach the end of the tail, which is naked; body cylindrical, mouth small with minute sharp teeth; nostrils tubular; dorsal fin commencing a little behind the head; vent nearly central; upper jaw much longer than lower.

(3865) *Dalophis anceps*, Cantor.

Syn. Plate VI. Figs. 1, 2, 3 4.

Ground-colour of head, back and upper half of sides yellowish white, so sparingly dotted with brown as to acquire a greyish or dusty appearance; beneath the lateral line a pale bluish grey longitudinal band; abdomen white; dorsal and anal hyaline, the lower half of the former dotted with brown. Iris silvery; orbital margin black; pupil circular, black. D 251? A 151, Br. XXXI? Inhabits *Sea of Pinang*. Total length: 1 foot, 8 inch. The head is comparatively short, terminating in a short conical muzzle; the eye very minute; the body is slender, cylindrical, but widens suddenly a little before the termination of the dorsal and anal; the naked tip of the tail is slightly compressed and much blunter than the muzzle. The head, measured to the gill-openings, $\frac{1}{16}$ of the total length; it is contained $10\frac{3}{4}$ times in the distance from the muzzle to the anus, which is situated at the end of the fourth-seventh of the total length. The very minute eye is situated at the commencement of the second-eight of the head, nearly above the middle of the lip; its distance from the muzzle is a little more than $\frac{1}{3}$ of the head; the distance between both eyes is a little less. The distance from the muzzle to the angle of the mouth is contained $4\frac{1}{2}$ times in the length of the head. Between the muzzle and each eye, on the crown of the head, appear three distant pores and five similar on each branch of the lower jaw. The anterior nasal apertures are tubular and open on each side of the point of the muzzle; although very small, each tube is double the length of the diameter of the eye; there are apparently no lobulets; the posterior nasal apertures open through the lower surface of the upper lip, beneath the eyes, as in *Ophiurus*. Beneath the tip of the muzzle appears a double series, each of three very minute pointed teeth. At a short distance behind the latter commences the series of the mesial line of the palate; the anterior part is double, each side consisting of fine teeth which are longer than all the rest, the posterior part is single. The teeth of the upper jaw are minute, distant and placed in a single series, which commences a little behind the anterior teeth of the palatal series. The lower jaw is shorter than the upper; the symphysis is naked; the teeth are minute, pointed and generally in a single series, but near the symphysis appears on each side a short internal series, consisting of three minute teeth. The tongue is very minute, elongated and tied to the floor of the mouth; it does not extend beyond the angle of the mouth. From the occiput to the tail the vertical diameter is contained $3\frac{1}{2}$ times in the length of the head; the tail slowly increases in depth to a little in front of the termination of the dorsal and anal, where the vertical diameter suddenly attains its maximum, $2\frac{1}{2}$ times in the length of the head. Between the termination of the dorsal and anal the vertical diameter is contained $4\frac{1}{2}$ times in the head, and it forms the base of the bluntly conical tip of the tail, the upper and lower margin of which slightly exceed the base. Owing to the lowness and thickness of the dorsal fin-membrane its precise origin cannot be determined; apparently it commences at a distance from the muzzle of $\frac{1}{8}$ of the total length, but the rays cannot be distinguished before a little in front of the anterior third of the total. The general length of the rays is $\frac{1}{8}$ of the head, but it slightly increases above the sudden enlargement of the tail near the termination of the fin. The anal commences at a short distance from the vent and resembles the dorsal. The gill-openings are small, crescent-shaped and placed between the lateral line and the abdominal profile without bordering upon either; the distance from the apparent commencement of the dorsal exceeds by $\frac{1}{4}$ the length of the head or the distance from the muzzle to the openings. The lateral line commences on the anterior third, but descends at a short distance from the head to the middle of the side and thus continues to the tip of the tail; it consists of a succession of short upwards-arched tubes, apparently, without pores. The species described by Russell (No. XXXVII. *Manti Bukaro Paumu*), which according to Cuvier is identical with *Cæcula pterygea*, Vahl, [*Skrivter of Naturhistorie*

Selskabet. Kjobenhavn. III. Pl. XIII. 1, 2.—*Sphagebranchus pterygea*, Cuv. *R. A.* II. 353 (2).—*Dalophis orientalis*, McClelland: *Calc. Journ. Nat. Hist.* V. 213.] differs from the present by its much shorter thicker head, and by the anus being situated in the middle of the total length. A solitary individual of *Dalophis anceps* occurred at Pinang, with two of *Ophiurus breviceps*, in November 1844.

Genus MURÆNA, ([*Artedi*,] *Linne*, 1766,) *Cuvier*, 1817. (Gymnothorax, *Bloch-Schneider*, 1801.—Muræenophis, *Lacepede*, 1803.—Lycodontis, *McClelland*, 1844.—Strophidon, *McClelland*. 1844.—Thærodontis, *McClelland*, 1844.) Pectorals none; branchiæ open on each side by a small hole; opercles thin; branchiostegous rays slender, concealed under the skin; stomach a short sac; air-vessel small, oval, placed towards the upper part of the abdomen.

(3866) *Muræna thyrsoidea*, Richardson. Plate V. Fig. 5. (Nat. size.)

Syn. Muræna thyrsoidea, Richardson: Ichth. Sulph, 111, Pl. 49.
Muræna thyrsoidea Richardson: Report, 1845, 314.
Muræna grisea, Bleeker: Verh. Bat Gen. XXII. 11.?

Head, body and fins of darker or lighter pitch colour, so closely and finely marbled and dotted with white or yellowish white, as not to affect the general dark colour; abdomen lighter than the rest of the body. Iris pale golden, minutely dotted with black.

D, C, A } 569 to 611, Br. IX.

Inhabits *Sea of Pinang*, Canton, China Seas. Total length: 2 feet 2 inch. The form of the body is compressed, of nearly uniform depth. The length of the head to the gill-opening is contained from $7\frac{1}{2}$ to $7\frac{2}{3}$ times in the total, or about $3\frac{1}{2}$ times in the distance from the muzzle to the anus. The horizontal diameter of the eye is $\frac{1}{10}$ to $\frac{1}{11}$ of the length of the head; the distance across the forehead is $1\frac{1}{3}$ diameter; the distance from the muzzle to the eye is two such; that from the muzzle to the angle of the mouth is about $\frac{1}{3}$ of the length of the head. The anterior apertures of the nostrils open through two small tubes, situated on each side of the muzzle, at a distance from one another of one diameter of the eye. The posterior apertures are small, oval, with a narrow membranous edge; each is placed above the forepart of the orbit. On the upper lip appear on each side four distant pores, and on each side of the lower lip appear similar ones. Sir J. Richardson has traced scales before the gill-opening. Both jaws are of nearly equal length and armed with two series of teeth. Those of the outer series are minute, yet strong, pointed with trenchant edges, and the series of both sides are uninterrupted on the symphysis of the upper jaw. Those of the inner series are more distant, thicker and longer. On the mesial line of the upper jaw appear four or five longer, distant, subulate teeth, which gradually increase in length, and are moveable. The rest of the mesial teeth are minute subulate, headed by one longer than the rest, which are at first placed in a double, but terminate in a single series. Neither tongue nor lateral line are distinguishable. The vertical diameter at the occiput is contained $2\frac{1}{3}$ times in the length of the head The anus is situated half the length of the head behind the middle of the total length. The gill-opening is small, oval and placed obliquely, nearer the abdomen than the back. The dorsal commences three diameters of the eye in front of the gill-openings. The rays increase in length towards the posterior half of the tail where they are $\frac{1}{3}$ of the length of the head. The caudal is but $\frac{1}{7}$ of the head and so closely attached to the dorsal and anal that its origin cannot be distinguished. The anal commences a little behind the vent: it resembles the dorsal. All the fin rays are double, and hid in the membrane. This species greatly resembles *Muræna tile*, [Syn. *Muræenophis tile*, Buchan. Ham. 18, 163. (*Synon. excl.*)—*Lycodontis literata*, McClelland: Calc. Journ. of Nat. Hist. V. 186, Pl. VIII. Fig. 2—*Lycodontis punctata*, McClelland, *ibid.* 187, Pl. VII. Fig. 3.—*Strophidon literata*, McClelland, *ibid.* 215.—*Strophidon punctata*, McClelland, *ibid.* 215.—*Strophidon maculata*, McClelland, (*Muræenophis tile baim*, Buchan. MS.) *ibid.* Pl. VIII. Fig. 1.] (Buchanan Hamilton,) which, however, may be distinguished by a slightly differing dentition, by the vent being situated one or two diameters of the eye before the middle of the total length, and by its colours. Single individuals of *M. thyrsoidea* occur at all seasons at Pinang.

(3867) *Muræna sathete*, (Buchanan Hamilton.)

Syn. Muræenophis sathete, Buchan. Ham. 17, 363.
Lycodontis longicaudata, McClelland: Calc. Journ. of Nat. Hist. V. 187, Pl. VIII. Fig. 2.
Strophidon longicaudata, McClelland: ibid. 215.
Muræna sathete, Richardson: Voy. Erebus and Terror, 91.

Head, body and fins dark greenish olive, throat and abdomen greenish yellow.

D, C, A } ? Br. IX. [Mr. McClelland counts: D 484, A 394, (l. c. 187.)]

Inhabits *Freshwater and Sea of Pinang*, Gangetic estuaries. Total length: 7 feet $8\frac{1}{2}$ inch. The general form of the body is cylindrical to the posterior half of the tail, which is tapering

and compressed. The length of the head to the gill-opening is $\frac{1}{15}$ of the total or about $\frac{1}{5}$ of the distance from the muzzle to the anus. The horizontal diameter of the eye is $\frac{1}{12}$ of the length of the head; the distance between the eye is two diameters; that from the muzzle to the eye $2\frac{1}{2}$ diameters; to the angle of the mouth it is contained $3\frac{1}{3}$ times in the length of the head. The apertures of the nostrils resemble those of *M. thyrsoidea*. The jaws are nearly equal. The teeth of the upper jaw are placed in a single uninterrupted series; they are distant, pointed, with two or three in front of each eye longer than the rest, which are generally small. The teeth of the mesial line commence with a single series of three moveable conical teeth, of which the second is the longest of all; behind it appears a double series of very small conical teeth, which, however, soon coalesce into a single series; opposite the eye commences a single series of palatal teeth which are conical and long. Those of the lower jaw consist of an external series, which is single uninterrupted and formed of small distant conical teeth; on the anterior half of each branch appears an internal distant series composed of four long conical teeth, of which the anterior ones are placed at a little distance behind the symphysis. No tongue is distinguishable. The lateral line is marked by a series of minute white pores which follow the middle of the side to the caudal. The vertical diameter at the occiput is contained $3\frac{1}{2}$ times in the length of the head; in front of the anus it is $\frac{1}{3}$ of, but in front of the caudal it is one diameter of the eye. The dorsal originates far in front of the gill-opening, at the commencement of the posterior third of the head: the distance from the muzzle to the dorsal is $\frac{2}{3}$ of the length of the head, that from the dorsal to the gill-opening $\frac{1}{3}$. The dorsal rays are short, and hid by the membrane; their length does not exceed $\frac{1}{5}$ of the head, of which the caudal is about $\frac{1}{11}$. The anus is situated at the end of the fifth-thirteenth of the total length; the fin commences at a short distance behind the vent; the rays are a little shorter than those of the dorsal. A single individual occurred on the coast of Pinang in May 1845; a second, a little shorter than the former, was taken the following July, in fresh water.

Genus LEPTOCEPHALUS, *Gronov.* 1754. Head small and short; teeth numerous; pectoral fins and gill-opening very small; body compressed and very thin, tape-like; dorsal and anal fins small, united at the tail, forming a point. A species of this genus was found in the stomach of *Johnius diacanthus*, (Lacepede,) taken at Pinang. The effects of the process of digestion were such as but to admit the following characters to be ascertained. The colour was a semi-pellucid opal, exhibiting numerous, somewhat distant striæ, or backwards directed angles, above and beneath the lateral line; the iris was bluish silvery, the pupil circular black. The vertical diameter at the occiput slightly exceeded $\frac{1}{4}$ of the greatest one of the body, which was about $\frac{1}{15}$ of the total length. The head was small, with a short very pointed muzzle. The profile of the forehead was oblique, meeting the horizontal one of the lower jaw, which nearly equalled the length of the upper; the length of the head was contained $17\frac{1}{2}$ times in the total; the distance from the muzzle to the posterior circumference of the orbit was $\frac{1}{3}$ of the length of the head. On each side of the upper jaw appeared five forwards-directed, pointed teeth, and in the intervals between them four smaller, similar ones. Each branch of the lower jaw was armed with five teeth, somewhat longer, but resembling those of the upper jaw; minute teeth appeared in the intervals between the three anterior longer ones. The roots of the pectorals were all that remained, and were placed close to the abdominal profile, immediately behind the gill-opening. The origin of the dorsal and anal fins could not be traced. The total length of the fish was $4\frac{1}{8}$ inches. From the peculiar dentition the species might be named: *Leptocephalus dentex*. A species of *Leptocephalus* occurs in the Bay of Bengal as far as the Sandheads. [Mr. McClelland quotes the Genus *Leptocephalus* as exclusively inhabiting Great Britain. (*Apodal Fishes of Bengal* in *Calc. Journ. of Nat. Hist.* V., page 226.)]

Fam. SYMBRANCHOIDÆ.

Genus SYMBRANCHUS, (*Bloch-Schneider*, 1801.) *Cuvier*, 1817. (Unibranchapertura, *Lacepede*, 1803.—Ophisternon, *McClelland*, 1844.) [*Note.* "Ophisternon:" (*Scr.* Ophiosternum.) "*A single transverse opening under the throat common to both branchiæ. These consist of four pectinated combs on each side. Two bands of teeth on the edges of the upper jaw, 5 short cartilaginous branchial rays. Eyes small and placed on the muzzle, teeth disposed in bands on the sides of jaws.*" (McClelland: Calcutta Journal, Nat. Hist. V. 220.) Of the preceding characters the following are erroneous: "*two bands of teeth on the edges of the upper jaw,*" and "5 *short cartilaginous branchial rays.*" The upper jaw carries but a *single* band of teeth, and there are *six* branchiostegous, *bony* rays on each side. After these errors have been corrected, it is evident that *Ophisternon*, McClelland, is identical with *Symbranchus*. Mr. McClelland himself quotes the diffinition of *Symbranchus*, Bloch, immediately preceding that of *Ophiosternum* (l. c. 175), yet, he observes: "*their branchiæ are not described further than that the membrane contains six strong rays.*" (l. c. 157.) As Cuvier, however, has confined his definition to the differential character by which *Symbranchus* is distinguishable from *Sphagebranchus*, the simple inference from his silence concerning the branchiæ is, that both genera have the same number (four) on each side.] Differs from *Sphagebranchus*

[*Note.* Sphagebranchus (Bloch-Schneider 1801.) Cuvier, 1817. Differs from *Murœna* principally by the branchial apertures approaching each other under the throat; the vertical fins in several species commence to project near the tail; muzzle extended and pointed; stomach like a long cul-de-sac; intestine straight; air-vessel long, narrow and placed far back.] by the branchiæ communicating outside by a single aperture, pierced under the throat and common to both sides; pectorals none; vertical fins nearly entirely adipose; head thick; muzzle rounded; teeth obtuse; opercles partly cartilaginous; six strong branchiostegous rays; intestinal canal straight; stomach distinguished by its being a little wider, and by a pyloric valve; cœca none; air vessel long and narrow. [The Asiatic species, quoted in the following, have no air-vessel.]

(3868) *Symbranchus caligans*, Cantor. Plate VII. Figs. 1, 2, 3.

Syn. Balut of the Malays.

(*Young ?*) Head above and back impure lake-coloured with livid reflections, lighter on the sides and abdomen; throat pale livid; dorsal-, caudal- and anal- membranes pale carmine.

D 0)
C 10) Br. VI.
A 0)

Inhabits *Sea of Pinang*. Total length: $8\frac{2}{8}$ inch. The head is conical, depressed, with rounded muzzle, swelling towards the occiput; the body is cylindrical with the sides slightly compressed, of nearly equal diameter; the short, tapering tail is greatly compressed like a two-edged sword. The length of the head, from the muzzle to the gill-opening, is contained $8\frac{1}{2}$ to $8\frac{3}{4}$ times in the total. The eye, a minute black speck, is situated nearly opposite the middle of the lip; its distance from the muzzle is $\frac{1}{7}$ of the length of the head. That from the muzzle to the angle of the mouth is $\frac{1}{5}$ of the length of the head. The minute anterior nasal apertures are situated on each side of the muzzle; their margins are raised, not tubular. The larger, posterior apertures are situated obliquely above the eyes; they are of a lanceolate form, with the broader part in front of and on a higher level than the eye, and with the apex extending downwards and outwards to the supraorbital margin. The lips are membranous, the under one reverted over the lower jaw, which is very little shorter than the upper. The teeth are all blunt and minute, yet there is a perceptible difference in their length. Each branch of the upper jaw carries a series of excessively fine, almost setaceous teeth, which under the symphysis become crowded and form a small triangular figure. The base of both triangles is bordered by three teeth larger than the rest, and separated by a naked longitudinal interval. The palatal teeth are longer than the preceding and are placed in a single close series, uninterrupted on the vomer. The teeth of the lower jaw are a little stronger than the palatal, and appear truncated; both branches carry a single series; both coalesce on the symphysis where they expand in a semilunar band, three or four teeth deep. The fleshy tongue is elongated, conical, with rounded apex, extending to the symphysis; it is moveable by means of a lax frænulum. The margins are thickened, rounded, forming a longitudinal groove along the upper surface of the tongue. Between the upper extremity of the hyoid bone and that of the anterior branchial arch appears a small blind fossa, without sac, like that discovered by M. Johannes Muller in another Indian species: *Symbranchus immaculatus*, Bloch. (*J. Muller*; *Myxinoiden in Abhandl. der Konigl. Akad. der Wissensch. zu Berlin.* 1839. *Berlin*, 1841, p. 245). On each side of the pharynx is a small oval fleshy tubercle, behind which a second one studded with minute card-like teeth, and immediately behind the middle of the posterior branchial arch appear a few similar teeth, forming a short linear group accompanying the arch. The lax undivided gill-membrane is externally marked by some longitudinal furrows; the posterior margin is backwards arched and extends to the upper third of the side, the origin of the lateral line. The bony branchiostegous rays are short, but strong, compressed and of equal length; the four upper ones are separated by a short interval from the two lower, which are also placed farther from each other than the preceding. Of the four densely fringed branchiæ the posterior is the shortest, and closely connected to the third branchial arch by a membrane with a small oval aperture in the middle. The lateral line is a groove commencing at the angle of the gill-opening, and continuing a little nearer the back than the abdomen towards the anus; it proceeds along the middle of the side of the tail to the caudal. The greatest vertical diameter, at the occiput, is contained $3\frac{1}{2}$ times in the length of the head; at the anus $4\frac{1}{2}$. The length of the tail varies from about $\frac{1}{5}$ to $\frac{1}{6}$ of the total. The skin is naked and lubricated by mucus. The membranous dorsal commences opposite the anus, but is not distinct on the anterior third of the tail. The anal resembles the dorsal; the height of either scarcely exceeds $\frac{1}{4}$ of the vertical diameter at the anus. Both unite with the short pointed caudal, which contains ten minute, jointed, simple rays. A solitary, apparently young, individual occurred at Pinang in September 1843; a second, $6\frac{1}{8}$ inch in length, in February 1845. The distance from the gill-opening to the heart slightly exceeds the length of the head. The digestive canal is a little less than $\frac{1}{2}$ of the total length. The œsophagus and stomach form an elongated cylinder, which gradually widens towards the pylorus, which is internally marked by a valve.

The duodenum, which is narrower than the fundus of the stomach is situated in the middle of the digestive canal. The intestines form a simple cylinder, widening towards the rectum, without cæcopyloric appendages or circumvolutions. The liver consists of a very elongated single lobe with many transversal incisions; it commences from the bulbus arteriosus, and gradually widening extends to a short distance from anus; the colour is pale reddish brown. The gall-bladder is small, oval, of a pale bluish green; it is attached to the liver at a short distance in front of the pylorus, or nearly halfway between the muzzle and the anus. The spleen is elongated oval, smaller than the gall, and situated closely behind the pylorus. There is no air-vessel. *Symbranchus caligans* differs from *S. gutturalis*, Richardson, (*Ichthyol. Erebus and Terror*, 49, Pl. XXX, Figs. 14—17.) from Dampier's Archipelago, by its proportionally longer head, and shorter tail: in the latter species the head is $\frac{1}{11}$ of, the tail less than $\frac{1}{3}$ of the total length, and there are 7 caudal rays. From *Symbranchus immaculatus*, Blochus. [Bloch. XII. 77, Tab. 419, Fig. 1. (*Excl. Habit. Surinam.*) Syn: *Synbranchus immaculatus*, Shaw, IV. 36.—*Symbranchus immaculatus*, Cuvier, R. A. II. 354 (²) —*Symbranchus immaculatus*, Muller, Myxinoid. in Abh. der Konigl. Akad. Berlin, 1839, 245.—*Ophisternon bengalensis*, McClelland: Calc. Journ. Nat. Hist. V. 197 and 220, Pl. XI. Fig 1-2.—M. Johannes Muller, l. c. points out the error committed by Bloch, who considered *S. immaculatus* is which he received from Tranquebar, to be identical with another distinct species inhabiting Surinam. To avoid confusion, a specific name requires to be given to the Brasilian species. *S. immaculatus*, is numerous in the Hooghly, and appears daily in the Fish Bazars of Calcutta. Individuals exceeding 14 inches in length, are rarely seen, but they are said to attain to two feet. The description of this species given by Mr. McClelland under the name of *Ophisternon bengalensis* is defective and disfigured by the following errors. The eyes are represented as being "placed before and external to the posterior apertures of the nostril;" the branchial rays are said to be five and to be cartilaginous, and the maxillary teeth are described and figured as "forming a crescent in front under the apex of the jaw." The posterior apertures of the nostrils are pierced vertically between, not behind the eyes; a tangent of the posterior margin of the aperture continued downwards, touches the posterior orbital margin; but a tangent of the anterior margin of the aperture, if prolonged vertically, divides the eye. There are six, bony, branchiostegous rays, and the maxillary teeth of both branches do not coalesce in a crescent beneath the symphysis, but are separated, and terminate in two small triangles as described in *S. caligans*. In a number of individuals of *Symbranchus immaculatus* the length of the head varied from $9\frac{1}{3}$ times in, to $\frac{1}{12}$ of the total, and that of the tail from $2\frac{1}{8}$ to $3\frac{7}{8}$. As observed by M. Johannes Muller, this species has several anatomical characters resembling those of *Amphipnous cuchia*, (Buchan. Hamilton) Syn. *Dondoo Paum*, Russell: XXXV.—*Unibranchapertura cuchia*, Buchan. Ham. 16, 363, Pl. XVI. Fig. 4. (*Synon. exclus.*)—*Symbranchus cuchia*. Cuv. R. A. II. 354 (²). (*Synon exclus.*)—*Cuchia*, Taylor in Gleanings in Science, II. 173.—*Synbranchus cashia*, Swainson II. 336.—*Ophichthys punctatus* Swainson, *ibid.*—*Amphipnous cuchia*, Muller: Archiv. 15, 1840.—*Amphipnous cuchia*, J. Muller: Myxinoiden in Abh. Berl. Akad, 1839, 244, (Berlin, 1841).—*Cuchia*, McClelland, Calc. Journ. Nat. Hist. IV. 411.—*Pneumabranchus striatus*, McClelland: Calc. Journ. Nat. Hist. V. 192 and 219, Pl. XIII.—*Pneumabranchus leprosus*, McClelland, *ibid*, 195 and 219.—*Pneumbranchus albinus*, McClelland, *ibid.* 196 and 219. *Dondoo Paum*, Russelli XXXV. has been identified by the examination of a specimen in the collection of Mr. Walter Elliot, who obtained it from the Ankapilly Lake. The discovery of the lung-like sacs of this eel belongs to James Taylor, Esq. late Civil Surgeon of Dacca, and has been acknowledged by Mr. Johannes Muller. Although the treatise entitled: "*Apodal Fishes of Bengal*," has added nothing new to our knowledge of the anatomy and habits of the fish, no reference is made in it to Mr. Taylor's original communication in '*Gleanings in Science*,' (l. c.) Russell discovered *Amphipnous cuchia* in the Ankapilly Lake; Buchanan Hamilton observed the fish in rivers and ponds of the South East parts of Bengal, and Mr. W. Griffith in Assam. In December 1848 an individual was taken in the Chenaub near our camp at Ramnuggur, and in February 1849 another was taken in the Jehlum not far from our Camp at Chillianwalla. (Punjaub.)] the present also differs by a proportionally longer head, and shorter tail. Of a number of *S. immaculatus* examined, the majority had 5 caudal rays, few 3, 6 or 7. In *Ophisternon hepaticus*, McClelland, (Calc. Journ. Nat. Hist. 198 and 221, Tab. XI. Fig. 3-4) the eyes are said to be placed "a little before the posterior openings of the nostrils." Both description and figures are too defective to identify the species.

Genus MONOPTERUS, ([*Commerson*] *Lacepede*, 1700,) *Cuvier*, 1829. (Ophicardia, *McClelland*, 1844.) ["Ophicardia: (Scr. Ophiocardia)." Two broad bands of teeth on the upper and one on the lower jaw; a single transverse opening under the throat, diverging on either side to the gills, which consists of three slightly pectinate fleshy combs; no scales, five rays in each side of the branchial membrane. There is but one species known and this has no air-vessel." (McClelland: *Calc. Journ, Nat. Hist. V.* 175.) The charac-

ters by which *Ophicardia* is supposed to differ from *Monopterus* are the assigned single transverse opening under the throat, and the five branchiostegous rays :—both characters, however, happen to be erroneous, as "*Ophicardia phayriana*," like a *Monopterus*, has *two branchial apertures* and *six branchiostegous rays*.] With the two branchial apertures united under the throat in a transversal fissure, divided in the middle by a partition ; dorsal and anal only visible in the middle of the tail and uniting at its point ; teeth like those of a card in the jaws and palatals ; branchiostegous rays six ; branchiæ three.

(3869) *Monopterus javanicus*, Lacepede. Plate V. Figs. 6, 7, 8. (Nat. size.)

Monopterus lævis, Richardson, Report. 1845, 315.
Monopterus cinereus, Richardson, *ibid.* 315.
Ophicardia xanthognatha, Richardson, *ibid.* 116 ?
Balut of the Malays.

(*Young.*) Head above, back and sides above the lateral line blackish brown with bluish reflections ; rest of the sides, throat and abdomen pale brownish blue ; fin membranes blackish. Iris pale golden, dotted with brown ; pupil circular black. Total length : $4\frac{5}{8}$ to $6\frac{3}{8}$ inch. (*Adult.*) Ground colour of head above, cheeks, back and sides above the lateral line reddish yellow ochre, or pale greenish yellow ; rest of the sides, throat and abdomen pale yellow ochre or buff ; head back and sides so densely spotted with blackish brown, as to leave but little of the ground-colour to view like single small spots ; cheeks, throat and abdomen with paler and fewer brown spots ; abdomen in some individuals not spotted ; lateral line of the ground-colour of the body. Iris light brown, with a narrow golden ring enclosing the pupil. [Specimens preserved in spirits of wine change the colours, and appear as described by Sir John Richardson. *Monopterus lævis.* "Corpore caryophyllaceo-brunneo immaculato, subtus pallidiori ; genis punctatis." —*Monopterus cinereus.* "The colour of the fish generally is lead grey, paler beneath, and thickly speckled on the back and sides with small points of hair brown. There are some pale streaks on the top of the head." (*Voy. Sulph. Ichth.* pp. 116, 117.) The drawing from which *Monopterus xanthognathus* was taken, has evidently been coloured from a living or fresh fish.] Total length : $10\frac{4}{8}$ to $20\frac{4}{8}$ inch. D 0, C 2, 3, 4 or 5, Br. VI. A 0. Inhabits *Sea of Penang, Malayan Peninsula*, Arracan coast, Sunda isles, China Seas (Hong-Kong, Canton, Chusan, Woosung). The general form of the fish is cylindrical, gradually tapering from the occiput, where the diameter is greatest, to the tail which is greatly compressed, like a two-edged sword, and tapers more suddenly than the body, terminating in a sharp point. The head is conical, swelling towards the occiput, the profile of which is more or less arched. Between the eyes the head is somewhat depressed, and the profile slopes towards the rounded depressed muzzle, which slightly projects beyond the rounded narrower apex of the lower jaw. Both individually and according to its age this species presents considerable variations in its external characters. The following have been found constant in a number of individuals of different size. The body is viscous and without scales. The eye is situated above the middle of the upper lip, almost bordering upon the profile : the form of the eye is oval, and it is obliquely placed, with the greatest diameter diverging backwards and downwards. The distance between the posterior margins of the eye is therefore greater than that between the anterior margins ; the distance from the eye to the muzzle, and that to the angle of lips are nearly equal. The anterior nasal apertures are very minute, with a slightly raised margin, but not tubular, and situated on each side of the muzzle ; the posterior ones open on the crown of the head ; although small, they are conspicuously larger than the anterior ; they are pyriform with the apex close to the centre of the supraorbital margin, and they are directed obliquely inwards, so that the distance between their fundus, which is a little beyond the anterior orbital margin, is less than that between the apex of both. The narrow lips are membranous, the upper one slightly, the lower very reflex ; their commissure is situated considerably less than half the distance between the muzzle and the gill-opening. The teeth are villiform, somewhat varying in length ; under a lens they appear conical, slightly recurvous, with a blunt apex. Those of the upper jaw form a narrow band, tapering towards the angle of the mouth ; at the symphysis the band of each limb forms a short linear process, separated by a linear naked interval. The palatal band resembles the maxillary, but both branches coalesce on the vomer

at an acute angle, and internally and externally the band is enclosed by a papillary fold of the membrane lining the palate, which gives the band the appearance of being broader than it really is. On each side of the pharynx, between the root of the posterior free gill-arch and the fourth appears a small rounded tubercle, studded with minute card-like teeth. Immediately behind the middle of the fourth, posterior arch, appears a short linear group of similar teeth. The teeth of the lower jaw resemble the rest; the bands of both branches taper towards the angle of the mouth; on the symphysis they either coalesce or are separated by a linear interval. Also this band is internally lined by a papillular duplicature of the membrane of that part of the mouth. The fleshy moveable tongue is elongated, tapering into a narrow flattened and rounded apex. The upper surface is papillular, like the roof of the mouth; the anterior half is flattened and thin, the posterior is thick, hollowed into a longitudinal channel between the two rounded margins, which Lacepede from the MS. of Commerson describes as two tubercles at the base of the tongue. Between the root of the upper extremity of the hyoid bone and the anterior gill-arch, but nearer the former, appears a small blind fossa, apparently without sac, like that of *Symbranchus*. The oblique gill-openings are almost confined to the abdominal surface, meeting at an acute angle on the throat; they are divided by a thin longitudinal septum, which does not, however, extend as far back as the angle of the gill-openings, and they consequently have the appearance of being single as in the Gen. *Symbranchus*. A fold, corresponding to the septum, appears on the external surface of the membrane. In the posterior half of each cavity appear three small, but slightly curved bony arches, with minute branchiæ. The fourth, posterior, arch is entirely hidden by the integuments. The branchiostegous rays are generally short, but unequal: the four upper ones are placed closely together, the two lower ones at some distance below the former; the second upper ray and the two lower ones are of nearly equal length, about double that of the remaining three. A linear groove marks the lateral line, which continues nearly in the middle of the side to the point of the tail. In specimens preserved in spirits of wine the contraction of the muscles produces another linear groove dividing the space between the back and the lateral line. All the preceding characters correspond to those of *Monoptere javanais*, Lacepede. The following are the characters which vary, not only according to age, but even in individuals of equal dimensions. The length of the head (measured from the snout to the hinder angles of the gill-openings,) varies from $\frac{1}{12}$ of, to $15\frac{1}{2}$ times in the total; the tail from $\frac{1}{4}$ of to $2\frac{2}{3}$ in the total length. Generally the head is proportionally shorter in the young, but the tail longer than in the adult. The distance between the eyes, across the forehead, is anteriorly about three-, posteriorly about four diameters of the eye. On the top of the head, on the uper lip and the throat appear some minute distant pores, the number of which varies individually. Of the three united fins the two are entirely membranous; the very small caudal encloses from two to five undivided rays, so very minute, that a lens is required to observe them through the semitransparent membrane. In adult individuals they are frequently not distinguishable. The dorsal commences a little behind the root of the tail, rising into a low arch above the middle of the tail and then gradually decreasing towards the caudal. The anal may be traced from the anus in the form of a raised line, sunk in a groove; on the posterior two thirds of the tail it forms a skinny hem, less elevated than the dorsal. Both are frequently very indistinct in individuals of all ages, and can then barely be distinguished by their semitransparency. Single individuals occur on the coasts of Pinang at all seasons. The constant characters occur in *Monopterus lævis*, Richardson, and in *M. cinereus*, Richardson; of the inconstant characters some are applicable to either.—*Ophiocardia phagriana*, McClelland, is described as having two short tubular nostrils at the extremity of the muzzle, and five branchiostegous rays. Both characters are erroneous, and the fish nowise differs from *M. javanicus*. —*Monopterus grammicus*, (Cantor,) [*Note*. Syn. *Symbranchus grammicus*, Cantor: Ann. and Mag. of Nat. Hist. IX. 30.—*Monopterus marmoratus*, Temminck et Schlegel: Fauna Japon.—*Monopterus marmoratus*, Richardson: Report. 1845, 315. This eel is numerous at Chusan in streamlets, canals and estuaries. As it is a favourite article of food, it is kept by the inhabitants of Chusan in large jars with fresh water. But it is capable of living a considerable time out of water. It is of voracious habits, feeding on smaller fishes,and it takes hooks baited with earthworms.] observed at Chusan and in Japan, presents the following differences. The head is contained about $10\frac{1}{2}$ times in the total length, the tail from $4\frac{1}{2}$ to 5, and in a japanese specimen it was about 7 times in the total. The head is consequently proportionally longer, and the tail shorter than in *M. javanicus*. The living individual examined in 1840 at Chusan had the head, back and sides above the lateral line of a reddish yellow ground-colour; the rest of a dark buff; the whole body covered with numerous black irregular lines, like inscriptions, leaving but little of the yellow and buff to view. In other external, and in anatomical characters they agreed with *M. javanicus*, and it remains to be ascertained if the above mentioned differences are constant, specific, or merely individual. The original of *M. xanthognathus*, Richardson

[*Voyage of H. M. S. Sulphur, Ichthyology*: 118, Pl. 52, Fig. 7.] is either *M. javanicus*, or *M. grammicus*, if the latter is a distinct species. In *Monopterus javanicus* the heart is situated at a distance behind the gill-opening of about 1½ times the length of the head. The digestive canal is about ⅔ of the total length. The œsophagus and stomach form a long canal, which gradually widens towards the pylorus, and is about ½ of the digestive canal; on the internal surface appper some longitudinal rugæ, which terminate at a short distance from the pylorus. The origin of the duodenum is internally marked by a very distinct valve, and externally by a considerable constriction. The coats of the stomach are perceptibly thicker than those of the intestines, which form a narrow cylinder without cœcopyloric appendages or circumvolutions, and widen a little towards the anus. The liver is linear, consisting of a single lobe, but subdivided by numerous small transverse incisions; it accompanies the stomach and terminates a little behind the pylorus.

ORDER PLECTOGNATHI.

Fam. BALISTISIDÆ.

Genus BALISTES, ([*Artedi*] *Linne*, 1748) *Cuvier*, 1817. Body compressed; in each jaw a single series of eight, generally trenchant, teeth; skin scaly or granulated, but not exactly osseous; anterior dorsal composed of one or more spines, articulated with a peculiar bone, fixed to the skull and furrowed to receive the spines; posterior dorsal soft, long, opposite to a nearly similar anal; ventrals none, but a pelvic bone suspended to those of the shoulder.

(3870) *Balistes conspicillum*, Bloch-Schneider.

Syn. Renard: I. 15, Fig. 88.
Baliste americain, Lacepede, I. 377, Pl. 16. Fig. 2.
Balistes conspicillum, Bloch-Schneider, 474.

Balistes conspicillum, Cuv. R. A. II. 373, note.
Rhinacanthus conspicillum, Swainson, II. 325.
Balistesconspicillum, Richardson: Report, 1845, 201.
Balistes conspicillum, Temm. et Schl. Fauna Japon. Pisces, Tab. CXXIX. Fig. I. (*Adult.*)

(*Young from* 1 *to* 3 *inch. in length.*) Head above, back and upper half of the sides pale rust-coloured or reddish brown, with more or less distinct snuff-coloured, short, longitudinally undulating lines or spots; lower half of sides, throat and abdomen impure brownish white with pale brown patches; in some on the sides of the head and body a few distant white dots: fins brownish white; second dorsal, caudal and anal with large brownish grey or black patches. Iris pale frosted silvery minutely dotted with brown; in some with three or four indistinct radiating brown bars; orbital margin blackish. (*From* 3 *to* 6 *inch. in length.*) Yellowish-, reddish- or blackish-brown, back darker, abdomen lighter than the rest; sides, throat and abdomen in some individuals with more or less distinct rounded whitish spots; [In one individual, taken off the Natunas Isles, (4° N. L. 108° E. in the southern part of the China Sea,) the body was said to be covered with blood red spots; after having been preserved in spirits of wine, it appeared of a uniformly blackish brown.] and in others an indistinct whitish forwards arched band from eye to eye; pectorals transparent brownish grey with a blackish spot at the root; rest of the fins brownish black, darker than the body; the basal half of their membranes in some individuals with very indistinct whitish spots. Iris pale silvery round the pupil; rest black. D 3 – 23, 24 or 25, C 10/1, A 20, 21 or 22, P 14 or 15, Br. VI. Inhabits *Sea of Malayan Peninsula and Islands*, Japan, China Sea, Natuans, Indian Ocean, Mauritius, Madagascar. Total length: 6 inch. When the pelvic spine is withdrawn the general outline of the body is oval. The length of the head, from the muzzle to the upper part of the gill-opening, is contained 3⅓ times in the total length. The anterior angle of the orbit is situated close to the profile above the centre of the length of the head, of which the horizontal diameter is ¼; the distance across the slightly arched forehead is a little less than two diameters. Each nostril has two small tubular apertures situated a little in front of the anterior angle of the orbit; the anterior aperture is directed forwards, the posterior backwards. The mouth is small with fleshy lips. In each jaw appear eight obliquely truncated, trenchant teeth, gradually increasing in size towards the symphysis. In the teeth of the upper jaw the internal surface is larger than the external, elongated oval, flattened with a rounded impression at the anterior part. In young individuals the internal surface is finely transversely furrowed, but with age it becomes smooth. The internal surface of the teeth of the lower jaw is almost entirely hid by a small crescent-shaped membrane. The tongue is small, rounded, fleshy and tied to the floor of the mouth. The anterior dorsal commences a little behind the anterior third of the back, the caudal not included; the first spine is very thick, with the anterior rounded margin prickly; the sides are smooth, longitudinally striated; the length is less than ½ of the head; but in very young individuals it is proportionally a little longer. The second spine, which at the root is in contact with the former, is much slenderer, smooth, and but ⅓ of the anterior; it is easily laid down, and when it reclines, the an-

terior trigger-like spine spontaneously follows. The third, slender spine is placed at a distance from the second of twice its own length, which is $\frac{1}{2}$ of that of the former; it may be reclined either forwards or backwards in the groove of the back. All three spines are connected by a lax membrane. The distance from the first to the third spine equals the length of the former, and also the distance from the third spine to the posterior dorsal fin. The latter is nearly equilateral triangular. The anterior four rays, of which the first and second are undivided, rapidly increase in length; the fifth and sixth are the longest, by $\frac{1}{3}$ longer than the first dorsal spine; the succeeding rays gradually decrease; the last, which is undivided, equals the third spine. The sides of all the rays of this and the remaining fins are covered with minute spines. The extent of the base of the second dorsal equals the distance of this fin from the first dorsal spine. Its distance from the caudal eqauls that from the third spine. The caudal is broad with the posterior margin convex; the length is a little less than the longest dorsal rays. The anus is situated opposite the first dorsal ray; the anal fin commences opposite the fourth; the extent of the base is a little shorter than that of the posterior dorsal; in other respects the two are equal and terminate opposite each other. The length of the rounded pectorals as a little more than $\frac{1}{3}$ of the head. The pelvic spine protrudes but very little, and is but slightly protractile; externally its length equals that of the longest dorsal rays; the triangular dewlap has the anterior and posterior margins equal, but the base, from the root of the pelvic spine to the anus, exceeds by $\frac{1}{3}$ the two margins. The vertical diameter of the occiput equals the length of the head; that in front of the posterior dorsal is contained $2\frac{1}{2}$ times in the total length; when the pelvic spine is protracted the greatest vertical diameter is $\frac{1}{2}$ of the total length. The body is covered with rhomboidal prickly scales. At a little distance beneath the back and behind the pectorals, each scale is provided with a central, backwards arched, small but strong spine, forming longitudinal series, of which upwards of 20 may be counted between the posterior dorsal and the anal, 10 on the tail. At the lower part of the dewlap these spines appear in clusters of from three to five. The stomach is capacious, elongated; it contained remains of fish; (in several, of *Exocoetus nigripennis*, Cuv. and Val.) The intestinal canal is wide, contained about $1\frac{1}{3}$ times in the total length. The liver is large; the right lobe consists of two elongated portions; the left is broader and deeply cleft. The gall-bladder is large, ovoid, expanded with a whitish green fluid; the spleen is small. The silvery air-vessel is elongated oval, occupying the upper part of the abdominal cavity. At Pinang and Singapore this species is numerous at all seasons.

Genus MONACANTHUS, *Cuvier*, 1817. Scales small, covered with stiff asperities, close like velvet; extremity of the pelvis salient and spinous; anterior dorsal fin with a large prickly spine, and a second almost imperceptible.

(3871) *Monacanthus tomentosus*, Linne.)

Syn. Seba: III. Tab. XXIV. Fig. 18.
Gronov. Mus. Tab. VI. Fig. 5.
Balistes tomentosus, Linne: Syst. 1463. Distinct from *Balistes tomentosus*, Bloch, Pl. 148. which Cuvier refers to *Pira aca*, Marcgr. 154. Mr. Swainson quotes the species of Bloch, (Sw. II. 327.)]
Balistes tomentosus, Shaw, V. 401, Pl. 169.
Monacanthus tomentosus, Cuvier, R. A. II. 373 (2).

(*Young.*) Yellow; dewlap washed with grey; except the throat and dewlap, the rest of the body with numerous small rounded cobalt blue spots; first dorsal spine yellow with three blackish rings, membrane bluish white minutely dotted with brown; posterior dorsal, anal and pectorals yellowish, transparent; caudal rays whitish, membrane black. Iris pale golden, orbital margin blackish. D 2—31, C 10 $\frac{1}{1}$, A 28, P 12, Br. VI. Inhabits *Sea of Pinang*, Indian Ocean. Total length; $3\frac{1}{8}$ inch. When the pelvic spine is withdrawn, the outline of the body is elongated oval. The length of the head, from the muzzle to a little behind the orbit, is contained $3\frac{1}{5}$ times in the total. The eye is situated at a little distance beneath the first dorsal spine, and above the pectorals and gill-openings; the horizontal diameter is $\frac{1}{4}$ of the length of the head and equals the distance between the eyes. The nostrils, lips, teeth and tongue resemble those organs of *Balistes conspicillum*. The first dorsal spine rises above the eye; is moderately strong, slightly arched and serrated both on the anterior and posterior margin; it is a little less than $\frac{1}{2}$ of the length of the head: the second spine is very slender, like a bristle and flexible, $\frac{1}{2}$ of the length of the former. Their connecting membrane extends but little behind the orbit; its distance from the posterior dorsal equals the length of the first spine. The first four rays of the posterior dorsal gradually increase in length; the fifth ray, from which the rest very slowly decrease, is but little longer than the horizontal diameter of the eye; the extent of the base is $\frac{4}{5}$ of the length of the head; the distance from the caudal is $\frac{1}{3}$ of the extent of the base. All the rays of the posterior dorsal, the small and the pectorals are undivided and spinous on their sides. The caudal is elongated, with the posterior margin rounded; all the rays except the upper and lower, are divided; the length of the central ones is $\frac{4}{5}$ of the head. Although the anal commences a little in front of the posterior dorsal, the extent of its base is not longer; in

other respects it resembles the dorsal. The pectorals are rounded, $\frac{1}{4}$ of the length of the head. The point of the pelvic spine barely projects beyond the integuments: the spine is large, arched; $\frac{3}{4}$ of the length of the head; it is very protractile, forming the anterior margin of the triangular dewlap: the base of the latter equals this margin; but the posterior margin is shorter by $\frac{1}{3}$. The vertical diameter of the protracted dewlap is contained $2\frac{1}{5}$ times in the total; in front of the posterior dorsal it is $\frac{1}{2}$ of the total. The whole body has a downy appearance from being covered with minute prickles, rough to the touch; those of the tail are a little longer than the rest. A solitary individual occurred at Pinang in July, 1844.

(3872) *Monacanthus geographicus*, (Peron).

Syn. Balistes geographicus, Peron.
Monacanthus geographicus. Cuv. R. A. II. 373 (1), Pl. XI. Fig. 2. (*Young*).
Monacanthus geographicus, Swainson, II. 327.

Ground-colour pale greenish blue with scattered small brown spots; from the anterior part of the base of the posterior dorsal to behind the eye an oblique, undulating, lilac brownish band, edged with whitish, and with numerous small brown spots; a second similar from the middle of the base of the posterior dorsal to beneath the pectorals; a third from the posterior part of the latter fin and the tail to the anus; these bands are frequently interrupted or broken up, so as to make the body resemble a geographical chart of islands; from the anterior part of the orbit three or four short radiating brownish bands; first dorsal spine greenish blue, indistinctly annulated with brown; membrane pale lilac clouded and minutely dotted with brown; rays of posterior dorsal, caudal and anal pale greenish blue; their membranes pale brownish lilac transparent; basal half of dorsal with three or four parallel undulating brown lines; and with a dark brown net-work; anterior two thirds of caudal with numerous brown dotted lines, parallel to the posterior margin, near which 6 or 7 pale blackish lilac confluent lines; lower part of the dewlap pale whitish lilac with small brown spots. Iris frosted silvery, with indistinct radiating brownish bars. D 2—29, 31 or 32, C $10\frac{1}{1}$, A 29, 30, 31 or 32, P 13 or 12, Br. V. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula.* Total length: $8\frac{1}{2}$ inch. When the pelvic spine is withdrawn, the form of the body is nearly rhombic. The length of the head, from the muzzle to a little behind the orbit is contained $3\frac{1}{3}$ times in the total. The eye is situated at a short distance beneath the first dorsal spine; the posterior margin of the orbit is immediately above the gill-opening; the horizontal diameter of the eye is contained $4\frac{1}{2}$ times in the length of the head. The outline of the forehead is concave, ascending towards the first dorsal spine; angular from side to side; the horizontal distance between the eyes equals one diameter. The nostrils, lips, teeth and tongue resemble those organs of *Balistes conspicillum*. The four upper branchiostegous rays are slender like hairs, the fifth is broad, sabre-like, with the upper margin elongated; it appears like two soldered together; the first dorsal spine is strong and a little backwards arched; the anterior surface is rounded, longitudinally furrowed and very prickly; the posterior is smooth, with about 7 strong downwards directed thorns on each side; the length of the spine equals the distance from the muzzle to the eye. The membrane is very short and completely envelops the minute slender second spine. The furrow of the back is very short and not intended to receive the first spine, which can but partially be laid down, so as not to touch the back, by reclining the second. The distance from the first spine to the posterior dorsal fin is undulating, gradually ascending, and equals the distance from the muzzle to the first spine. All the rays of the posterior dorsal are undivided, with minute spines; the first is but little shorter than the second and third, the longest, which are $\frac{2}{3}$ of the first dorsal spine. The succeeding rays gradually decrease; the base is very sloping; its extent equals the distance from the first dorsal spine. The distance from the caudal is $\frac{1}{3}$ of the base. The anal fin is placed opposite to the posterior dorsal which it resembles. The caudal is broad rounded; in individuals from 5 inches in length and more, the upper, undivided ray, and the adjoining half of the second, divided one, project beyond the others, and form a kind of short filament. The length of the central rays are in young individuals $\frac{1}{4}$, in older $4\frac{1}{4}$. in the total. The pectorals are rounded, $\frac{1}{3}$ of the length of the head. The pelvic spine is strong, nearly $\frac{1}{4}$ of the total length, and very protractile. Near the scarcely projecting apex is a deep naked incision in the anterior margin, with five strong upwards directed thorns. At the incision there is no joint in the spine, but there is one a little lower down, so that the thorny apex of the spine is freely moveable both forwards and backwards. The figure in *Regne Animal* incorrectly represents the pelvic spine with two backwards moveable pieces. The dewlap is large, triangular, with the lower part arched, scaleless and half transparent; in it are enveloped upwards of 33 tendinous lines, the points of which slightly project beyond the margin; as many of them are divided, they have the appearance of rays. The shape of the expanded dewlap is in early age triangular; with age the posterior angle becomes truncated. The base of the triangle equals the length of the pelvic spine; the arched lower margin is by one third shorter. When the dewlap is expanded, the vertical diameter at the first dorsal spine is contained $1\frac{2}{10}$ times in the total

length; between the posterior dorsal and the anal it is $2\frac{1}{3}$. The whole body is covered with minute crowded, backwards directed spines; near the upper and lower margin of the tail appears a longitudinal series of four larger scales, each armed with a short but strong forwards arched spine. Individuals less than above four inches in length, present no trace of these spines. This species has lateral line, the course of which is distinguished by a line of spines a little larger than the rest. It commences the posterior margin of the orbit, ascending slightly towards the posterior dorsal, when it abruptly descends towards the middle of the side, and then continues straight to the caudal. At its origin it gives off a short vertical branch to the root of the first dorsal spine; a second above the orbit, and nostril towards the muzzle; a third along the lower margin of the orbit, where it subdivides in an upper branch which proceeds horizontally to the chin, and in a lower undulating obliquely downwards to the dewlap. At Pinang this species is numerous at all seasons.

(3873) *Monacanthus penicilligerus*, (Peron.)

Syn. Balistes penicilligerous, Peron.
Monacanthus penicilligerus, Cuv. R. A. II. 374 (2), Pl. XI. Fig. 3.
Chætodermis penicilligerus, Swainson II. 327.

Ground-colour pale whitish green, with numerous black lines; those round the orbit radiating, those of the rest of the head and the body longitudinal, undulating; side by side, behind and between the eye and gill-opening, two large round purplish black spots, both longitudinally divided by a band of brilliant ultramarine, through which passes one of the black lines of the body; behind the orbit a smaller purplish black spot, edged with pale blue, and three similar, vertically placed between the middle of the posterior dorsal and the anal; along the base of the latter fins, the dewlap and the caudal several irregular black spots; spines of the body hyaline; lips and filaments whitish red, the latter dotted and ringed with black; dorsal spine whitish grey with black spots; membrane hyaline, dotted with brown; fin-rays brownish white, membranes hyaline; those of the posterior dorsal, caudal and anal with numerous small rounded black spots placed in series parallel with the base of the fins. Pupil black, horizontally elliptical; iris golden bronze, with six radiating pale crimson bars. D 1—23 or 26, C $10\frac{1}{2}$ A 21 or 24, P 13, Br. V. Inhabits *Sea of Pinang, Singapore*. Total length: $6\frac{1}{2}$ inch. The form is rhombic, but appears shorter and broader than that of *M. geographicus*. The length of the head from the muzzle to a little behind the orbit, is contained $3\frac{1}{5}$ times in the total. The posterior margin of the orbit is situated nearly in the middle between the dorsal spine and the gill-opening the horizontal diameter of the eye is $\frac{1}{4}$ of the length of the head; the horizontal diameter between both exceeds the diameter by $\frac{1}{3}$. The nostrils, lips, teeth and tongue resemble those organs of *Balistes conspicillum*. The upper branchiostegous ray is the longest, and closely attached to the second, which at its root appears to be double; the fourth is setaceous like the preceding, but a little removed from them; the fifth is broader than the rest, but less so than it is in *M. geographicus*. The dorsal spine is proportionally longer in young individuals; it is tetragonal, slightly arched backwards, and is armed with strong thorns on the four margins and it carries numerous long filaments like those of the body. It can but slightly be reclined; its length is less than $\frac{1}{2}$ of its distance from the muzzle; its membrane descends from the middle of the posterior surface, and extends to a little in front of the middle of the distance between the two dorsals. There appears to be no second spine. The interval between the dorsal spine and the first ray forms three slight undulations, and slightly exceeds the length of the spine. The length of the rays of the posterior dorsal differs but slightly; those in the middle, the longest, are $\frac{2}{3}$ of the spine. The extent of the base equals the distance from the muzzle to the dorsal spine. The anal commences opposite the 4th or 5th ray of the posterior dorsal, but it terminates opposite the latter. The distance of both from the caudal is $\frac{1}{4}$ of the extent of the posterior dorsal. The caudal is nearly rhomboidal; the length of the central ray is $\frac{1}{4}$ of the total. The pectorals are rounded, their length equals that of the longest rays of the posterior dorsal. The pelvic spine is very strong, less protractile than that of *M. geographicus*, but the jointed apex is more projecting; the dewlap is small, triangular, the anterior margin and the base equal the length of the caudal; the posterior margin is $\frac{1}{3}$ less. When the dewlap is protracted, the vertical diameter between the root of the dorsal spine and apex of the pelvic is contained $1\frac{2}{3}$ times in the total length; at the second dorsal it is $2\frac{1}{6}$. The body is very rough, covered with short strong spines, generally terminating in two, but frequently in more points, of which the posterior is longer than the rest and directed obliquely backwards. The spines of the body are disposed in longitudinal series; those of the head are smaller, crowded and not in series; those of the tail are different from those of the rest of the body. No lateral line is perceptible. The filaments of the body are rather long, varying from one to three diameters of the eye; they consist of a main trunk, tapering to a brush of fine branchlets, and from three to seven lateral branches, placed in quincunx, each subdivided in minor branches, with fine brush-like points. On the sides of the head and body the filaments are few and widely scattered; they appear in greatest number round the lips, on the forehead, on both

sides of the dorsal spine, in the interval between the dorsals, and on the margin from the chin to the apex of the pelvic spine. Two individuals, $3\frac{4}{8}$ and $4\frac{4}{8}$ inches in length, were observed at Singapore in May 1840, a third, $6\frac{4}{8}$ inch, occurred at Pinang in October 1844.

Genus ALUTARIUS, *Cuvier*, 1817. Body elongated, covered with minute close granules, scarcely visible to the naked eye; a single spine in the anterior dorsal fin; pelvis entirely hid beneath the skin and without the spinous projection of *Balistes* and *Monacanthus*.

(3874) *Alutarius obliteratus*, Cantor.

Balistes monoceros, Bloch, Tab. 147?
Balistes monoceros, Shaw, V. 399, (excl. Syn. *B. monoceros* Linné) Pl. 168?
Alutera: Bloch 147 Cuv. R. A. II. 374 (*) [According to Cuvier different from *Balistes monoceros*, Linné, Catesby 19. (*Regne Anim* l c.)
Alutera monoceros, Bloch 147, Swainson, II. 327?

(*Young*, $3\frac{1}{8}$ *inch in length*.) Head above and back pale blackish brown; upper half of the sides pale yellowish olive, with numerous half effaced, irregular, blackish brown spots; lower half of the sides, throat and abdomen light impure greenish yellow, pale silvery; first dorsal spine, membrane and caudal yellowish olive, the latter with three backwards arched, indistinct blackish bands, of which the anterior a little behind the root, the second in the middle, the third along the posterior margin; posterior dorsal, anal and pectorals pale transparent yellowish. Iris greenish yellow. ($7\frac{2}{8}$ *inch in length*.) Ground-colour darker; back with numerous oblique or vertical spots; sides of head, body and abdomen with similar larger ones of irregular form, all the spots of a pale, half-effaced, blackish colour; caudal rays yellowish olive, membrane hyaline, closely and minutely dotted with black; posterior margin blackish. D 2—46 or 47, C $10\frac{1}{1}$, A 47, 48 or 49, P 14, Br. VI. Inhabits *Sea of Pinang*. Total length $7\frac{2}{8}$ inch. The form is broad lanceolate, the abdominal profile a little more arched than the dorsal. The length of the head, from the chin to a little behind the orbit, is about $\frac{1}{3}$ of the total. The eye is situated in the centre between the first dorsal spine and the upper extremity of the gill-opening; the horizontal diameter is a little less than $\frac{1}{5}$ of the length of the head. The frontal outline gently slopes from the first dorsal spine to the muzzle; that of the throat is more oblique and continues in a moderate arch to the anus. The horizontal distance between the eyes exceeds that diameter of each eye by $\frac{1}{3}$. In front of the eye appear two tubular nasal apertures, contiguous and both directed backwards; the anterior is the larger and closed by a small membranous valve. The lips are very thin, membranous, and scarcely cover the teeth. The latter are very pointed; in other respects they as well as the tongue resemble those organs of *Balistes conspicillum*. The linear gill-openings are placed obliquely, with the upper extremity opposite the posterior margin of the orbit, the anterior extremity extends a little farther than the orbit; in its course the gill-opening deviates a little downwards from the corresponding profile of the forehead; its length exceeds by $\frac{1}{3}$ the horizontal diameter of the eye. The five superior branchiostegous rays are setaceous, gradually decreasing in length towards the sixth, which is the shortest, and broad, like a sabre. The first dorsal spine is rather slender slightly arched, tetragonal and armed with thorns on all four margins; the membrane is very small and completely covers the second spine. The latter is excessively minute, yet distinct. The length of the first spine equals that of the gill-opening; its distance from the muzzle is $\frac{1}{3}$ of that of the body, not including the caudal; from the posterior dorsal it is a little less. The latter interval deviates but slightly upwards from the horizontal. The second dorsal commences a little in front of the centre of the total length; it is generally low; the longest rays, towards the middle, equal the length of the gill-opening; the base is sloping, and equals the distance between the chin and the first dorsal spine. The interval between the last dorsal and root of the upper caudal ray is contained $2\frac{1}{2}$ times in the extent of the posterior dorsal fin, it equals the vertical diameter of the root of the caudal, but it is $\frac{1}{2}$ of the length of the latter. The anal commences a little in front of the posterior dorsal, and terminates a little farther back. In very young individuals the caudal is bluntly pointed, $\frac{1}{6}$ of the total length; in older ones it becomes rounded, and scarcely exceeds $\frac{1}{8}$ of the total. The rounded pectorals commence behind the lower half of the gill-opening, which latter they scarcely exceed in length. The greatest vertical diameter of the body, at the first dorsal spine, is $\frac{1}{3}$ of the total length; that at the first ray of the posterior dorsal is less by $\frac{1}{4}$. Four solitary individuals were at considerable intervals observed at Pinang. Shortly after death the spots of the body almost entirely disappear, and specimens preserved in spirits of wine acquire a pale dark slate-colour. They might be mistaken for *Alutarius berardi*, Lesson, [Voy. de la Coquille, Ichth. 107, Pl. 7. Syn. *Aleuteres berardi*, Richardson, Ichth. of Sulph. 132, Pl. 61, Fig. 1.—*Aleuteres berardi*, Richardson, Report, 1845, 202 and 318.—*A. cinereus*, Temminck et Schlegel: Fauna Japonica: Pisc. Tab. CXXXI. Fig. 1,] but the latter species is distinguished by a proportionally shorter head, a smaller eye; the anal fin commences a little behind the posterior dorsal, and the distance between the latter and the caudal equals the length of the caudal, and is consequently proportionally greater.

(3875) *Alutarius lævis*, (Bloch).

Aleuteres lævis, Richardson, Ichth. of Sulph. 131, Pl. 61. Fig. 3.
Aleuteres lævis, Richardson, Report, 1845, 202.

Ground-colour bright yellowish green olive; round and beneath the orbit, between the two dorsals, on the cheeks, throat and abdomen single short, longitudinal or oblique, ultramarine bands; the rest of the head and body with numerous distant rounded ultramarine spots; first and second dorsal spine, and their membrane, and the caudal rays yellowish olive, dotted with black; caudal membrane pale greenish white, densely dotted with brown and with four indistinct reddish brown bands, of which the anterior a little behind the root of the fin, the fourth on the posterior margin; rest of the fins hyaline. Iris golden bronze, orbital margin blackish. D 2—46, C 10½, A 49, P 14, Br. VI. Inhabits *Sea of Pinang*, Indian Ocean, Canary Islands, Carribean Sea, China Sea. Total length: 9⅝ inch. The form is elongated lanceolate, broader at the tail than at the muzzle. The length of the head is contained 3⅔ times in the total. The length of the head, from the chin to a little behind the orbit, is contained 3⅔ times in the total. The eye is situated between the first dorsal spine and the upper extremity of the gill-opening, a little closer to the former than to the latter; the horizontal diameter is ⅓ of the head. From the muzzle the profile gently ascends to the first dorsal spine, the corresponding profile from the chin to the anus, describes a gently rising arch, so that the outline of the head is elongated conical with the point truncated. The horizontal distance between the eyes equals two diameters. The nostrils, lips, teeth and tongue resemble those organs of *A. obliteratus*. The upper extremity of the oblique linear gill-opening is situated in the middle between the centre of the lower orbital margin and the root of the pectorals; the lower extremity extends to a little in front of the orbit; the length equals the horizontal diameter of the eye. The first dorsal spine is slender and flexible and covered with granules like those of the body; its length is ⅓ of its distance from the muzzle, which is contained 4½ times in the total length. The membrane is small completely hiding the minute second dorsal spine. The groove of the back is ⅓ of the length of the first spine which, however, does not sufficiently recline, so as to come in contact with the back. The interval between the two dorsals ascends gently backwards, and equals the distance from the muzzle to the anterior margin of the orbit. The posterior dorsal is low, the longest rays exceeding the horizontal diameter of the eye by ½; the extent of the base equals the distance from the muzzle to the first dorsal spine; the distance between the last dorsal and the root of the upper caudal ray equals the verticle diameter at the root of the caudal both are contained 2½ times in the extent of the base of the posterior dorsal. The anus is situated opposite the third ray of the posterior dorsal; the anal commences opposite the 6th, and extends farther back than the opposite fin, which it otherwise resembles. The caudal is very large, broad oval; the central rays, the longest, equal the length of the head. The rounded pectorals slightly exceed the longest dorsal rays. The verticle diameter at the first dorsal spine and at the first dorsal ray, equal the distance between the spine and the muzzle; in the centre between the two dorsals the diameter equals the head. A single individual was observed at Pinang in December 1842. Shortly after death the body became shining blackish, a shade lighter than the blue marks, which changed to intense bluish black.

(3876) *Alutarius barbatus*, (Gray.) Plate VIII. Fig 1.

(*Icon.*) Balistes (Anacanthus) barbatus, Gray: Ill. Ind. Zool. 1. Pl. 84, Fig. 2.
Anacanthus barbatus, Gray: Zool. Miscell. 8. [The following are Mr. Gray's character: "Anacanthus. Body long, lanceolate, compressed, covered with small scales; head produced, beak-shaped mouth small; under lip one bearded; pelvis produced, bag-like, with a single rather long spine in front; dorsal fin one long; anal long; tail long, lanceolate; most allied to *Alutera* (*les Aluteres*, Cuv.). "*Anacanthus barbatus*, Illust Ind. Zool. Pisc. t. 1. f. 2. Brown, rather paler beneath; under part of the jaws, body and ventral pouch whitish, marbled with black lines; anal fin produced a little beyond the dorsal fin; tail nearly half as long as the body, D 46, V 11, A 60, P 8? Singapore." (Zool. Miscell. 1831, p. 8.) Comparison of preserved specimens of this fish with the plate in the Illustr. of Ind. Zoology. leaves little doubt that the latter is an incorrect copy. The draughtsmen has overlooked the anterior dorsal fin and added a ventral spine and pouch. These two are the principal distinguishing characters of the Gen. *Anacanthus*. Both however, are erroneous: the fish is a true *Alutarius*, and the genus *Anacanthus* is inadmissible.]
Psilocephalus barbatus, Swainson, II 327. [Psilocephalus, Swainson, 1839 is a second genus founded upon the figure of *Anacanthus barbatus* in Ill.

Ind. Zool. It is thus doubly inadmissible being a synonyme of *Anacanthus*, and being founded upon erroneous characters.]

Dark bluish green slate-coloured; filament of the chin black; spine of the anterior dorsal pale bluish green, membrane hyaline, minutely dotted with black; posterior dorsal, anal and pectorals transparent brownish white, rays pale yellowish brownish yellow; caudal rays yellow, membrane black. Pupil black, horizontally oval; iris silvery.

D $\begin{cases} 1—44, \\ 1—47, \\ 1—50, \\ 1—51, \end{cases}$ C $8\frac{2}{2}$, A $\begin{cases} 65, \\ 61, \\ 62, \\ 59, \end{cases}$ P 9, Br. VI.

Inhabits *Sea of Pinang*, *Singapore*. Total length: $9\frac{3}{8}$ inch. The form of the body is narrow, very elongated, resembling the blade of a knife; the sides compressed, the abdomen nearly trenchant. The head is very elongated, gradually attenuated towards the muzzle; its length from the chin to a little behind the orbit is $\frac{1}{5}$ of the total, or very little more or less. The eye occupies the commencement of the posterior fifth of the head: it is situated beneath the spine of the anterior dorsal, close to, without encroaching upon the profile; the horizontal diameter is $\frac{1}{6}$, rarely $\frac{1}{8}$ of the length of the head; the horizontal distance between the eyes is but $\frac{2}{3}$ of their diameter. The two apertures of each nostril are minute, tubular, opening side by side immediately in front of the anterior margin of the orbit. The lower jaw is longer than than the upper, beyond which the rounded chin projects; the mouth is a small transversal cleft which opens vertically on the upper part of the muzzle; the lips are thin, membranous; the teeth, apparently 8 in the upper, 6 in the lower jaw, do not differ from those of the preceding species of *Alutarius*. To the chin is attached a vertical, soft, fleshy filament, tapering from the base into a sharp point, its length exceeds $\frac{1}{2}$ of the head. Between the branches of the lower jaw, from behind the filament to the lower extremity of the gill-opening, the skin of the throat is lax and forms a kind of narrow, slightly downwards arched dewlap. The floor of the mouth rises gradually towards the second third of the head, where the three very elongated branchial arches commence. The rest of the cavity is a very narrow tube which closely follows the gently backwards ascending profile of the forehead. No distinct tongue is visible. The gill-opening is linear, downwards arched and very oblique; commences beneath the anterior angle of the orbit, on a level with the root of the pectorals, the distance from which, as well as the length of the opening itself, but slightly exceeds the horizontal diameter of the eye. The branchiostegous rays are setaceous. The pelvic spine is narrow like the blade of a sabre, and in six individuals examined, so completely hid in the integuments, as not even to encroach upon the abdominal profile which is very slightly arched. Nor did they offer the least trace of a triangular dewlap, as represented in the figure Hardwicke's Illustrations. The profile of the back rises but little and slowly from the muzzle to the posterior dorsal, from the termination of which it gently descends; the abdominal outline is but little more arched. The anterior dorsal consists of a single spine placed above the pupil, in front of the pectorals; it is very slender, setaceous, covered with minute spines; in all individuals observed, it reclined in its dorsal groove, but might readily be raised; the membrane is small triangular, apparently without a second spine. The distance between the dorsal spine and the posterior dorsal fin is by $\frac{1}{4}$ shorter than that between the spine and the chin. The upper margin of the posterior dorsal is a little arched; the rays towards the middle are the longest, and equal the length of the spine; the extent of the base exceeds by about $\frac{1}{6}$ the length of the head; the interval between the last dorsal and the root of the upper caudal ray varies from a little less than $\frac{1}{2}$ of, to $2\frac{1}{3}$ times in the extent of the fin. The anal resembles the posterior dorsal, but it commences a little more forwards behind the anus, and is carried farther backwards, so that its extent at the base exceeds that of the former by $\frac{1}{4}$ or $\frac{1}{5}$, while its distance from the caudal is $\frac{1}{3}$ less than that of the former. The caudal is very elongated, lanceolate; the two upper and lower rays are, like those of the other fins, undivided; the margins of all rays have a series of microscopic spines. On each side of the root of the caudal appears a triangular pointed space, covered with minute hair-like spines, like the rest of the body. The length of the central rays vary in the different individuals from $2\frac{2}{3}$ times in, to $\frac{1}{3}$ of the total. The upper rays of the pectorals, the longest, slightly exceed $\frac{1}{4}$ of the length of the head. The body is covered with little rounded scales and has a fine velvety appearance from its being densely covered with minute, microscopic spines. The lateral line is so fine that it is hardly visible to the naked eye. Behind the orbit, at its origin, it sends two branches round the orbit, of which the upper one accompanies the profile to the muzzle, the lower ascends to a little in front of the eye and then proceeds parallel to the upper branch. The main trunk at first ascends obliquely, but soon descends with 3 to 4 short undulations to a little in front of the posterior dorsal, from whence it continues in the middle of the side and terminates at the apex of the scaly part of the caudal. The vertical diameter at the upper lips slightly exceeds $\frac{1}{4}$ of the length of the head; at the dorsal spine it is a little less than $\frac{1}{4}$; the greatest, between the two dorsals is $\frac{1}{5}$; at the root of the caudal it is a little less than $\frac{1}{6}$ of the head. The greatest horizontal diameter, or thickness of the

body, is a little behind the anterior dorsal fin, where it equals 1½ diameters of the eye; from thence it gradually decreases and becomes trenchant towards the tail like the entire abdominal part of the fish. A single mutilated individual was observed at Singapore in May 1843; five others, of which the smallest measured 8 inches in length, occurred at Pinang in the following November, in February and August and December 1844, and in June 1845. After death the colour of the body changes to a dusty pale reddish brown, dotted with black, the caudal membrane turns pale bluish grey; the arched lax skin of the throat shrivels up, so as scarcely to be visible.

Genus TRIACANTHUS, *Cuvier* 1817. With a kind of ventrals, each supported by a single large spinous ray, adhering to a not salient pelvis; anterior dorsal with three or four small spines behind a very large one; skin covered with crowded small scales; tail longer than in the other sub-genera.

(3877) *Triacanthus biaculeatus*, (Bloch.)

Triacanthus biaculeatus, Richardson: Rep. 1845, 202.
Triacanthus biaculeatus, Bleeker: Verh. Batav. Gen. XXII. 6.

Head above and back pale blackish green, lighter on the sides above the lateral line; rest of the sides of body and head and abdomen frosted silvery; in some a faint blackish spot a little below the eye; first dorsal spine silvery blackish, the rest white; the basal half of the spines as well as the yellowish membrane black; ventral spines silvery white; rest of the fins pale yellowish in some the margins blackish. Iris pale golden, bluish black towards the orbit. D 5—24 or 25, C 14/1, A 19 or 20, V 1, P 14, Br. VI. Inhabits *Sea of Malayan Peninsula and Islands*, Indian Ocean, Ceylon, Bay of Bengal, Sumatra, Java, Borneo, Madura, Sumdawa, Celebes, Seas of China and Australia. Total length: 9 inch. The form is trapezoid, approaching the rhomboidal. The head is broad, pyramidal, tapering to an elongated muzzle; the length from the latter to the gill-opening varies from ¼ of to 4½ times in the total. The eye borders upon the profile; the anterior margin of the orbit is situated opposite the commencement of the posterior third of the head; the oblique diameter is ¼ of the length of the head; the distance of the eyes between the anterior angles equals the diameter, between the posterior angles it is ⅔ more. The two tabular apertures of each nostril are placed obliquely in front of the eye upon profile; the upper aperture is oval, larger than the lower, rounded one. The small mouth is surrounded by thick fleshy lips; each jaw has an external series of 10 trenchant teeth, of which the central ones are the largest; in the upper jaw appears a second transversal series of four tubercular teeth, of which the central pair are the larger; in the lower the corresponding series consists but of two tubercular teeth, immediately behind the pair on the symphysis. The tongue is small fleshy, oval and tied to the floor of the cavity. The gill-opening is linear, slightly oblique, situated immediately in front of the pectorals; the length nearly equals the diameter of the eye. The distance from the muzzle to the root of the first dorsal spine varies from ⅓ of to 3½ times in the total length. The spine is strong, covered to the apex with small bipartite or tripartite spines; in young individuals its length equals the greatest vertical diameter of the body, in older ones it is ¼ to ⅓ less. The second spine is much shorter, slenderer, and but slightly rough on the posterior margins; its length varies from ⅕ to ⅐ of the former; the succeeding rays gradually decrease in length, the last one varying from ⅓ to ½ of the second; the connecting membrane is a little shorter than the spines; the extent of the anterior dorsal slightly exceeds ½ of the distance from the first spine to the first ray of the posterior dorsal, which varies from ⅙ of to 5½ times in the total length. The posterior dorsal is low, gradually rising from the first, undivided, ray to the sixth, and then slowly decreasing; the longest ray is 1⅔ diameter of the eye; the extent of the fin nearly equals the length of the head; the distance from the root of the upper ray of the caudal varies from ¾ to ⅞ of the extent. The anal is falcated; it commences opposite the 9th or 10th ray of the posterior dorsal, and terminates opposite the last ray; the first ray is undivided, ½ of the second, the longest, which varies from 1½ to 2 diameters of the eye; the succeeding rays suddenly decrease to the 11th or 12th, from whence the remaining rays are but ¼ of the longest. The anus is situated immediately in front of the fin. The caudal is deeply divided in two pointed, or a little rounded lobes, of which the upper one is generally the longer, equalling the extent of the posterior dorsal. The pectorals are rounded, their length varying from 1⅓ to two diameters of the eye: they are placed immediately behind the gill-opening, opposite the first dorsal and the ventral spines, but nearer the latter. These spines are as strong, and rough as the first dorsal, but shorter, their length varying from ⅓ to a little

more than $\frac{1}{2}$ of the head ; each is attached by a short thick rough membrane to its respective groove on each side of the very elongated, flattened pelvic spine, which is covered with little scales, not different from those of the rest of the body. The latter are very small, sub-rhomboidal with the vertical diameter much longer than the horizontal. Each scale (Plate IX. Fig. 3. Magnified.) carries a single vertically placed crest, which is armed with from 4 to 15 excessively minute spines. The skin is rough to the touch in every direction. The hair-like lateral line commences behind the orbit, describing a wide arch which terminates opposite the posterior third of the posterior dorsal, from whence it proceeds in the middle of the side of the tail to the caudal. At its origin the line gives off the following branches ; a vertical, anastomosing in front of the dorsal spine with the one from the opposite side; a second along the supraorbital margin, in front of the nostril, along the profile to the muzzle ; a third along the infraorbital margin, obliquely undulating over the cheek ; a little behind the mouth it suddenly ascends to join the opposite corresponding branch ; a fourth descends a little in front of the gill-opening, beneath which it forms a short arch backwards, and then proceeds obliquely downwards to the middle of the ventral groove. At Pinang and at the Sandheads young individuals are excessively numerous at all seasons ; larger ones are rarely seen, particularly in the latter locality.

(3878) *Triacanthus strigilifer*, Cantor. Plate IX. Fig. 1 and 2. (*Young* ?) Head above and back pale sea green, changing to bluish white on the upper half of the sides ; lower half and abdomen frosted silvery white ; back and sides with a few orange spots of irregular form, viz. an elongated spot between the eyes towards the nostrils ; a second, broad rhomboidal surrounding the base of the anterior dorsal, and sending a vertical branch, with rugged margins, down to the gill-opening ; a third oblique spot from the third to the eleventh ray of the posterior dorsal ; immediately behind the mouth a vertically placed pair of small spots ; a pair of larger ones, of which the lower like a horse-shoe, on the cheek beneath the nostril ; beneath the eye a horizontal band to the lower part of the gill-opening ; in the axilla a short horizontal band, giving off an irregular branch towards and above the anal, and a longer arched one to opposite the middle of the posterior dorsal ; at a short interval another horizontal band terminating in the middle of the side, a little behind the posterior dorsal ; in the centre of the base of the caudal a small rounded spot ; on the posterior half of the tail a broad forwards pointed spot of bright yellowish green ; first spine of anterior dorsal pale sea-green, minutely dotted with black ; succeeding spines white ; membrane hyaline, minutely dotted and edged with black ; pectorals and ventral spines white ; rays of the rest of the fins yellowish white, membranes hyaline. Pupil horizontally oval, black ; iris light yellow golden, orbital margin greenish black. D 5—22. C 12½, A 16, V 1, P 13, Br. VI. Inhabits *Sea of Pinang*. Total length : 6⅝ inch. This species differs from the preceding by its more elongated, less deep form, by its larger eye, its peculiar scales, its longer second dorsal spine, its number of fin rays and colours. From the muzzle to the lower angle of the gill-opening the head is $\frac{1}{4}$ of the total length. The eye borders upon the profile, occupying the posterior third of the length of the head, of which the horizontal diameter is $\frac{1}{3}$; the distance between the anterior angles of the eye equals the diameter ; that between the posterior ones is $\frac{1}{4}$ longer. The nostrils, lips, teeth and tongue resemble those organs of *T. biaculeatus*, but the gill opening is proportionally shorter, being but $\frac{3}{5}$ of the diameter of the eye. The distance from the muzzle to the first dorsal spine is a little less than $\frac{1}{3}$ of the total length. The spine resembles that of *T. biaculeatus*, equalling the greatest vertical diameter of the body. The second spine is remarkably long, $\frac{1}{2}$ of the former, and the length of the connecting membrane corresponds ; the extent of the fin, and its distance from the posterior dorsal are the same in both species. The longest ray of the posterior dorsal is proportionally shorter, being $\frac{2}{3}$ of the diameter of the eye, but its distance from caudal is greater : it equals the extent of the base, which is $\frac{5}{6}$ of the length of the head. The falcated anal commences opposite the 12th ray of the posterior dorsal, and terminates opposite the last ray ; the longest ray slightly exceeds the diameter of the eye ; the extent of the base is proportionally shorter than in *T. biaculeatus*. The caudal is less deeply cleft almost crescent-shaped ; the lobes equal ; their length is contained 4½ times in the base of the posterior dorsal. The pectorals are rounded, their length slightly exceeding the diameter of the eye. The ventral spines resemble those of *T. biaculeatus* ; but the intermediate pelvic spine is in the present proportionally longer, and covered with larger scales, entirely different from those of the rest of the body ; their form is hexagonal with excessively minute spinous crests radiating to the margins. The scales of the body (Plate IX. Fig. 2. Magnified), although small, are perceptibly larger than in *biaculeatus*, and with their horizontal diameter longer than the vertical ; their form is nearly rhombic with from three to seven vertical or oblique crests, each of which is armed with three to seven excessively minute spines. Each scale thus resembles a small curry-comb, which makes the skin in every direction rough to the touch. The main trunk of the lateral line resembles that of *biaculeatus*, but it gives off an additional vertical branch to the middle of the root of the first dorsal spine, a little behind the anterior anastomosing one. The

two branches surrounding the eye can be traced no farther than the region of the nostrils; and the one in front of the gill-opening appears to terminate at the lower angle of the opening. A solitary individual occurred at Pinang in June 1845. Several years before, the existence of a second species of *Triacanthus* was positively asserted by fishermen who described it as being very rarely seen, and of a size somewhat smaller than *T. biaculeatus*.

Fam. OSTRACIOIDÆ.

Genus OSTRACIUM, (*Linne*, 1748) *Cuvier*, 1817. Head and body covered with bony, regular plates, instead of scales, soldered so as to form a kind of inflexible armour; the tail, fins, mouth and a kind of small lip covering the margin of the gill-opening are the only moveable parts, all passing through holes in the armour, also the greater number of vertebræ are soldered together; each jaw with 10 to 12 conical teeth; ventral fins and pelvis none; dorsal and anal small; branchiostegous rays six.

Lactophrys [*Lactophrys*. Swainson, 1839. In *Nomenclator Zoologicus*, *Pisces*, p. 33, this Sub-Genus is by mistake written *Laetophrys*. while in *Addenda*, p. 3, *Lactophrys*, De Kay. 1842, is quoted as a distinct genus. In the Zoology of New York, III. 341, *Lactophrys* is quoted with the evidently accidental omission of the name of the founder, but the characters are those of Mr. Swainson. *Nat. Hist. of Fishes* &c. II. 324.)] cornutus, Swainson, II. 324.
Ostracion cornutus, Richardson, Report, 1845, 200.
Ostracion cornutus, Temm. et Schl. Fauna, Jap. Pisces Tab. CXXXI. Fig. 4, (*Young.*)
Buntal kumbang of the Malays.

Young. (Without spines; 1 inch in length.) Upper surface and sides pale greenish yellow, with a sky-blue central spot in some of the hexagons, and here and there with a single brown spot; abdomen light reddish yellow; generally with a single brown spot on the throat, and one or two on the anterior part of the lateral margin; fins hyaline. *Older.* Upper surface and sides pale greenish olive, minutely dotted with black; with a central sky-blue spot in each hexagon; abdomen yellowish white; fins transparent pale olive; caudal minutely dotted with black; posterior half blackish; spines buff, minutely dotted with black. Iris bright yellow, orbital margin orange or red; pupil obliquely oval, irridescent black. D 9, C 8½, A 9, P 11, Br. VI. Inhabits *Sea of Malayan Peninsula and Islands*, Chinese Seas, Canton, Japan. Total length: 6 inch. The form of the body is tetragonal, with the lower surface broader than the upper, and the sides concave. The length of the head is ¼ of the total. The forehead is at a nearly right angle with the vertex; the vertical diameter through the eye, the greatest of the body, is contained 3½ times in the total length; that through the gill-opening is a little shorter; at the termination of the armour it is 5½ times in the total length. The eye is situated close to the frontal angle; the greatest oblique diameter is ½ of the length of the head. Above each eye rises a subular, forwards, upwards and outwards directed spine, granulated at the base; the rest finely fluted; the length equals the head. The distance between the eyes across the vertex is excavate, a little less than two diameters. The nostrils have two minute, apparently papillular apertures, placed in a small, nearly vertical furrow close to the anterior angle of the eye. A little in front of the lower aperture appears a minute papilla. Each jaw has a single series of ten small conical teeth, almost entirely hid by the fleshy lips; the teeth are of a dark amber or chestnut brown; the four above the symphysis of the lower jaw are a little longer than the rest. The mouth is very small; the tongue is minute, fleshy and completely tied to the floor of the mouth; behind the tongue there is a small raised step, leading into a tunnel, on each side supported by the four branchial arches. The sides of the back are angular, a little contracted in the middle. A little in front of the dorsal, at the widest part of the back, appears on each side a small pointed tubercle, between which the distance equals the length of the head. The centre of the back is raised, so as to form a linear sharp keel which terminates in a small pointed tubercle in the middle between two lateral ones. The abdominal surface is both longitudinally and transversely arched; the greatest transversal diameter, about the middle, is contained 2¾ times in the total length. On each side of the termination appears a spine resembling the frontal ones, but pointed in an opposite direction and a little shorter. The armour is composed of pentagonal, hexagonal or heptagonal pieces with the margins finely toothed or ciliated. The pieces of the back and sides have each a tubercle in their centre, from which radiate a number of lines corresponding to the respective number of sides. On the pieces of the abdomen appear instead of lines a number of minute hemispherical tubercles. The dorsal fin is placed

at a short distance from the termination of the armour above; its length is $\frac{1}{2}$ of the head; the extent of the base is $\frac{1}{2}$ of the length. The length of the small naked tail is contained about $2\frac{1}{2}$ times in the elongated oval caudal fin. The rounded anal is situated above, yet between the posterior pair of spines, behind the dorsal which it resembles. The rounded pectorals are nearly $\frac{3}{4}$ of the length of the head. The smallest individuals examined measured 1 inch in length. They had no spines, but in their places appeared tubercles. The central and lateral tubercles of the back were comparatively more developed than in the adult. In the middle of the upper pupillary margin of the iris appeared a small notch. The smallest ones, provided with blunted spines half the length of the head, measured $1\frac{4}{5}$ inch in length. Young individuals are at Pinang numerous at all seasons.

(3880) *Ostracium tesserula*, Cantor. Plate VIII. Fig. 2 and 3. *Young.* Armour bright gamboge with numerous small black spots, not corresponding to the centre of the polygons, and fewer and more distant on the abdomen; tail bright gamboge with one or two black dots on each side of the root of the caudal; fins gamboge, a little paler than the body; pectorals with a single black dot at the root; caudal with the posterior margin pale blackish. Pupil transversely oval, black; iris bright gamboge, orbital margin orange; in the middle of the upper pupillary margin a small notch. D 9, C 8½, A 9, Br. VI. Inhabits *Sea of Pinang*. Total length: 2 inch. The general form is tetragonal. The back is elongated oval, arched from the occiput to the tail; in the centre appears a short longitudinal crest, on each side of which is a deep furrow, laterally bounded by the sharp angular margin. By these three crests the vertical section in this particular region becomes pentagonal. The profile of the forehead is nearly straight and steep. The distance between the anterior angles of the orbits is $\frac{1}{4}$ of the total length; the greatest breadth in the middle of the back is contained $2\frac{2}{3}$ times in; above the naked tail it is $\frac{1}{11}$ of the total length. The abdominal surface is both longitudinally and transversely arched, with a furrow along the angular margin; it is broader than the back, its greatest breadth, beneath the pectorals, varies from $1\frac{2}{3}$ in to $\frac{1}{2}$ of the total length. The sides are excavated with the lower margin projecting farther outwards than the upper; their greatest diameter is nearly in the middle and is contained $2\frac{1}{2}$ times in the total length; but the vertical diameter of the central crest of the back is a little longer, owing to the central convexity of the abdomen. The armour is composed of hexagonal pieces with very finely toothed or ciliated margins. From the centre of each hexagon radiate towards the margin six raised lines, of which the central, horizontal ones, join their neighbours, so as to form on the sides of the armour seven parallel, horizontally arched, lines, which form the bases of triangles produced by the other obliquely radiating lines. On the back and sides the triangles are very conspicuous, while the hexagonal outline of the component pieces can scarcely be traced. On the abdominal surface the reverse is the case. From the central tubercle radiate numerous fine lines; but the triangles are very indistinct. The length of the head is contained a little less than $3\frac{1}{2}$ times in the total. The eye is situated close to the profile, nearly in the middle between the gill-opening and the muzzle; the horizontal diameter is $\frac{1}{3}$ of the length of the head. The supraorbital arch forms a tubercular protuberance. The mouth, teeth, and tongue and nostrils resemble those of *O. Cornutum*, but there appears to be no nasal papilla. The dorsal is placed close to the termination of the armour; the upper margin slopes backwards; the anterior ray, the longest, is $\frac{1}{2}$ of the length of the head, of which the extent of the base is $\frac{1}{4}$. The anal is but little farther backwards than the dorsal, opposite the middle of which is placed the first ray; in form and length it resembles the dorsal. The caudal is elongated oval; its length $\frac{2}{3}$ of the head. The pectoral is broad, nearly triangular; the third ray, the longest, equals the caudal. This fish is of rare occurrence at Pinang. Of four individuals observed at irregular intervals, the length varied from 2 to 1 inch. They appear to be young individuals. The triangular partitions of the armour characterise *O. turritum*, [Syn. *Ostracion turritus*, Forsk. 5. 7, No. 113; —Bloch. Tab. 136;—Shaw. V. 425, Tab. 171; —Cuv. R. A. Ed. 1, II. 154;—Ruppell: Atlas, 5, and Neue Wirb. Fische, 61;—*Tetrasomus turritus*, Swainson, II. 323.] Forskal. Possibly the present fish may be the young of that species, prior to the appearance of the spines and the full development of the dorsal crest.

(3881) *Ostracium nasus*, Bloch.

Syn. Ostracion nasus, Bloch, Tab. 139.
Ostracion nasus, Shaw, V. 426, Pl. 171.
Ostracion nasus, Cuvier, R. A. Ed. 1. II. 154 (5).
Ostracion nasus, Swainson, II. 323.
Buntal panjang of the Malays.

Upper surface pale brownish or greenish olive, with numerous small rounded dark brown spots; sides lighter of either colour; in some the margins of the polygons dark brown; abdomen either uniformly buff with the margins of the polygons pale lilac, or pale reddish yellow with the nuclei of the polygons greenish white; the naked tail brownish olive, lighter on the sides, with numerous brown spots; beneath greenish buff; lips, margin of gill-openings and root of pectorals pale greenish olive with few brown spots; fins pale transparent greenish olive; a round brown spot at the root of each dorsal ray, and a few similar scattered over some of the cau-

dal rays. Orbital half of iris pale greenish olive with few brown spots, rest bright yellow with a blackish or orange ring; pupil black, circular. *Young.* With a few rounded brown spots irregularly scattered over the sides. D 9, C 8½, A 9, P 11, Br. VI. Inhabits *Sea of Pinang, Malayan Peninsula,* "Indian and American Seas," (Bloch.) Total length: 7⅛ inch. The form is nearly quadrangular, as the breadth of the abdomen but slightly exceeds that of the back and the height of the sides. The back is elongated lanceolate; from the nasal protuberance the profile gently ascends towards the middle of the back, when it slowly descends towards the tail, the whole forming a very low arch. From the occiput to near the dorsal the middle of the back is raised and forms a low triangular keel, on each side of which appears a shallow broad sulcus, outside bordered by the raised angular margin of the side. The triangular forehead slopes gently from the occiput and appears a little excavated owing to the broad protuberant supra-orbital margins. The breadth between the anterior angles of the orbit is ⅔ of the length of the head; between the posterior angles it equals the head; the greatest breadth, in the middle of the back, exceeds the length of the head by ¼, ⅕ or ⅙, according to the individually more or less projecting nasal protuberance; the breadth at the termination of the armour is a little less than half the breadth between the posterior orbital angles. The nasal protuberance is blunt, rounded. In individuals 6⅝ inch in length it scarcely projects beyond the mouth, immediately above which the profile rises vertically, and this portion measures ½ of the distance between the anterior angle of the orbit and the protuberance, which in them is ⅛ of the total length. In the largest individual, 7⅛ inch in length, the protuberance perceptibly projects beyond the mouth, from which the profile projects obliquely and exceeds ½ of the stated distance, which is ⅛ of the total length. The sides are but little excavated; their greatest vertical diameter corresponds to, but slightly exceeds, the greatest breadth of the back; it varies from 4⅙ to 4⅐ times in the total length. The length of the head, from the nasal protuberance to the gill-opening, is in younger individuals, with the protuberance but little developed, ⅕ of the total, in older ones it is contained 4½ times in the total. The eye is close to the profile; the posterior angle of the orbit is situated above the gill-opening. The greatest diameter is a little oblique, ascending backwards; it is contained 2½ times in the distance from the mouth to the gill-opening, and this proportion appears to be constant. But as the development of the nasal protuberance increases with age, so does the relative length of the diameter of the eye vary from 2½ times in to ⅓ of the distance, measured from the protuberance to the gill-opening. The nostrils, mouth and tongue resemble those of *O. tesserula.* Each jaw carries a single close series of from 9 to 11 conical teeth of a chestnut or brown colour. The six central teeth of both jaws are a little larger than the rest and their points become blunted with age. The armour is composed of pentagons, hexagons and heptagons, with ciliated margins. Not including the lateral half-series, on the back and sides appear five longitudinal ones; nine pieces from the gill-opening to the tail. The abdomen is covered by nine longitudinal series of which the central one is composed of 12 to 14 pieces. All are closely covered with minute bony tubercles, generally arranged parallel to the margins. The dorsal commences opposite the anus; the upper margin is rounded; the third and fourth ray, the longest, slightly exceed ½ of the length of the head; the extent of the base is ½ of the length. The anal commences opposite the last ray of the dorsal, which it in form and length resembles. The caudal is broad triangular with the posterior angles and margin rounded; the two central rays the longest, equal the head. The pectorals are broad triangular; the third and fourth upper rays are the longest, ⅗ of the length of the caudal. The length of the sides of the naked tail is ¾ of the caudal. Single individuals, or two or three together, were observed at Pinang at long and irregular intervals. In size they differed but slightly, the smallest being 6⅜ inch in length.

Fam. GYMNODONTIDÆ.

Genus DIODON, *Linne,* 1766. All the teeth united into a single one in each jaw; behind the trenchant margin of each a rounded part, transversely furrowed and forming a powerful apparatus of mastication; the skin armed with stout spines; no ventral fins.

(3882) *Diodon triedricus,* Cuvier.

Syn. Seba II. XXIII. 4.
Diodon triedricus Cuvier: Mem. du Mus. IV. 133.
Diodon triedricus, Cuv. R. A. II. 367 (1)

Head above, back and sides to a little below the gill-opening pale tortoise-shell brown; a transversal band composed of a large soot-coloured spot behind each pectoral, and a series of smaller spots across the back; a second similar but paler band in front of the dorsal; rest of the sides and abdomen yellowish white; fins whitish grey, minutely dotted with brown; all spines brown; their roots of the colour of the part they occupy. (*From a preserved specimen.*) D 12, C 9, A ? P 19. Br. ? [In *Mem. du Mus.* IV. Cuvier gives six, in *Regne Animal* five branchiostegous rays.] Inhabits *Sea of Pinang,* Total length: 6 inch. All the spines are compressed with the anterior margin convex, sharp and continued over the anterior, horizontally forwards directed root. The two posterior roots are placed at nearly right angles with the anterior. The roots are generally longer than the spines of which the longest ap-

pear on the sides of the back and body. Two longitudinal series of spines of the mesial line of the back, and three of the abdomen are shorter than the rest. There are three spines above the upper half of the orbit, three at the lower, and one at the angle of the mouth. The throat is naked, with a single small bony protuberance beneath the symphysis of the lower jaw. Between the eye appear three spines, viz. a central and the anterior one of the three supraorbital; between the pectorals across the back appear four spines. The upper part of the back carries four longitudinal series, viz. two central, each of eight, both terminating with an odd spine at a little distance in front of the dorsal fin, and two lateral series each of five spines, of which the anterior commences a little behind the pectoral fins, the posterior is situated between the dorsal and the caudal. This fish is of very rare occurrence at Pinang. The only one observed was a specimen which on account of its rarity had been kept preserved for several years, and was thus rendered unservicable for more minute examination.

Genus TETRODON, *Linne*, 1766. The jaws divided in the centre by a suture, so as to present the appearance of four teeth; two above and two beneath; the skin armed with small, slightly projecting spines; ventrals none.

I. Cuvier: *Regne Animal*, II. 368 (1). *Species with short head, capable of inflating themselves so as to attain a globular form. Entire body rough.*

A. *Immaculate.*

(3883) *Tetrodon immaculatus*, Lacepede.

Syn. Lacepede, I. XXIV. 1.
Russell, XXVI. Kappa.
Tetrodon immaculatus, Cuv. R. A. II. 368 (1).

Young. Head above and back pale greyish olive, lighter on the sides of the head and upper part of the body; abdomen pale yellow ochre; axilla and the smooth spot inside the pectorals blackish; the whole body minutely dotted with brown; spines white, those of the back with black points; pectorals, anal and dorsal pale transparent olive, base of the latter blackish; caudal pale brownish with single indistinct whitish spots; upper, lower and posterior margin black. Iris olive. D 10, C 9½, A 9, P 17, Br. V. Inhabits *Sea of Pinang*, Madras. Total length: 3⅛ inch. The length of the head, measured to the margin of the gill-opening, is contained 4¼ times in the total. The eye, bordering on the profile, is situated a little nearer the gill-opening than the muzzle; the horizontal diameter is ⅕ of the head; the distance across the forehead is a little less than 2 diameters. The double, contiguous nostrils are situated in front of the eyes; each aperture is pierced through a small papilla, and both appear like a minute simple tentacle. The jaws are nearly equal, the four teeth normal; the tongue is globular, fleshy, tied to the floor of the mouth. The dorsal is fan-shaped; the first, undivided, ray is situated a little behind the commencement of the posterior third of the back, the caudal not included; the extent of the base is ¼ of the head, of which the longest ray is ⅓. The first anal ray is situated behind the dorsal, at the commencement of the posterior fifth of the body; in shape and dimensions it resembles the dorsal. The caudal is broad with the posterior margin rounded; its length equals the head. The pectorals are broad and rounded, ⅓ of the length of the head. The lips, the throat, the space in front of the eyes, and that covered by the pectorals, and the tail from midway behind the dorsal, obliquely down a little in front of the anal, are all naked and smooth. The rest of the body is covered with crowded fine hair-like spines. A solitary young individual was observed at Pinang in September 1844. Russell observed but the mutilated specimen, which he described and figured.

B. *With black spots.*

(3884) *Tetrodon simulans*, Cantor. Head above and back light yellowish or greenish olive, paler on the upper half of the sides of head and body; head, back and sides with numerous rounded, irregular or confluent spots, blackish brown or olive or black; throat and abdomen white, sparingly dotted with brown; spines white, fins pale olive, transparent, minutely dotted with black; anterior half of caudal with three or four more or less distinct backwards arched blackish bands, posterior half blackish. Iris bright yellow dotted with black. D 12 or 13, C 8⅔, A 10 or 11, P 19 or 21, Br. V. Inhabits *Sea and estuaries of Pinang, Malayan Peninsula, Singapore.* Total length: 1 foot. The length of the head is contained 3¼ times in the total. The eye is situated in the middle of the head, bordering on the profile; the horizontal diameter is contained 5½ times in the length of the head; the distance between the anterior angles of the orbits is 2 diameters; between the posterior angles 2½ such. There are no nostrils, but close in front of the anterior angle of the orbit appears a flattened simple tentacle. The upper jaw slightly projects beyond the lower; the tongue resembles that of *T. immaculatus*. The rounded dorsal fin occupies the commencement of the posterior fourth of the back; the three first rays are undivided; the fifth and sixth are the longest, ⅓ of the head, and equal the extent of the base. The anal is placed opposite the dorsal, which it resembles, but the extent of the base is a little shorter, and but the two first rays are divided. The caudal is broad, with the upper, lower and posterior margins convex; its length is ⅔ of the head. The pectorals are broad, rounded; their length equals that of the dorsal. There is no lateral

line. The spines are rather long, fine and somewhat distant; above they extend from the between the eyes to near the dorsal; beneath from behind the throat to near the anus, which is situated a little in front of the anal. Young individuals of this species are at all seasons excessively numerous on the Malayan coasts. In general form and in distribution of colours, it bears a striking resemblance to *T. fluviatilis*, Buchanan Hamilton, [*Fishes of the Ganges* 6,361. Pl. XXX. Fig. 1.—*T. fluviatilis*, Cuv. R. A. II. 368 (1).] which latter differs in having distinct simple nostrils, in number of fin rays and other characters. The present belongs to the Sub-Gen. *Arothron*, Muller. [Arothron, *Müller*: "On each side a solid tentacle containing the large olfactorian nerve; an annular muscle round the eye, and a kind of eyelid." (*Abh. Berlin. Akad.* 1839, 252 (1). Berlin 1841.)]

C. *with black bands.*

(3885) *Tetrodon carduus*, Cantor.

Head above and back dark yellow ochre with a number of longitudinal, slightly serpentine black lines continued to the caudal; sides of the head pale ochre with irregular black spots; sides of the body pale lilac whitish with a few distant black spots, disposed so as to form 4 or 5 vertical series; abdomen very pale ochre; dorsal and ventral, pale transparent olive, minutely dotted with black; caudal rays reddish yellow, membrane whitish dotted with black, and with vermicular black spots; pectorals pale yellow, with a blackish narrow band along the base. Iris orange dotted with black. D 11, C $9\frac{1}{1}$, A 10, P 17, Br. V. Inhabits *Sea of Pinang*. Total length: 6 inch. The length of the head is contained $3\frac{1}{2}$ times in the total. The eye is situated nearly in the centre of the length of the head, bordering upon the profile; the horizontal diameter is $\frac{1}{7}$ of the head; the distance between the anterior angle of the orbits is nearly three diameters; between the posterior four. No nostrils appear, but their place is supplied by two small black tentacles, the one close above the other. The jaws are nearly equal, the teeth and tongue normal. The dorsal occupies the commencement of the posterior fifth of the back; it is fan-shaped, with the first ray undivided: the longest rays are $\frac{1}{3}$ of the head, or twice the extent of the base of the fin. The posterior margin of the caudal is convex; the longest rays are $\frac{1}{3}$ of the head. The anal resembles the dorsal; it commences, nearly opposite the middle of the distance between the dorsal and the caudal. The pectorals are rounded, their length equals that of the dorsal. The spines are rather long, very fine, hair-like and crowded. On the back they commence from between the nasal tentacula and extend to the caudal, in front of the base of which there is but a small naked space. The lips, the chin and the space inside the pectorals are also spineless. A single individual was observed at Pinang in December 1842. This species is nearly allied to *T. virgatus* Richardson (*Zool. Erebus and Terror*, 62, Pl. XXXIX. Fig. 8-9,) from which it differs in the dorsal being situated farther back; in the relative position of the latter fin and the anal, and in the greater number of black lines of the back. In the present the latter are twelve: in *T. virgatus* six. It is also allied to *T. meleagris*, Solander. [Syn. Lacep. I. 535.—Bl. Schn. 507.—*T. meleagris* Richardson: *Ichth. Sulph.* 122, Pl. 57 Fig. 1-3, and *Voy. Samarang* p. 19.]

D. *with pale Spots.*

(3886) *Tetrodon testudineus*, Linne.

Syn. Tetrodon testudineus, Linne: Amoen. Acad. I. 306, Tab. 14, Fig. 3.
Tetrodon testudineus, Linne, Syst. 1444.
Tetrodon testudineus, Bloch. Tab. 139.
Tetrodon testudineus, Shaw, V. 444, Pl. 178.
Tetrodon testudineus, Cuvier, R. A. II. 368 (1).
Tetrodon testudineus, Swainson, II. 328.

Young. Head above, back and upper part of the sides reddish brown with numerous rounded and elongated milk-white spots, minutely dotted with brown; rest of the sides and abdomen reddish yellow with a number of drawn brown parallel bands, downwards arched and increasing in length, interrupted, or two joined, towards the tail; caudal dark brown with numerous whitish spots; rest of the fins yellowish, transparent, blackish at the base. Iris reddish yellow dotted with black. D 10, C $8\frac{1}{2}$ A 10, P 15, Br. V. Inhabits *Sea of Pinang*, Indian Ocean. Total length: $3\frac{2}{3}$ inch. The length of the head is contained $3\frac{1}{2}$ times in the total. The eye, bordering on the profile, is a little nearer the muzzle than the gill-opening; its greater diameter, rising obliquely backwards, is $\frac{1}{5}$ of the length of the head; the distance between the anterior angles is two such diameters; three between the posterior. The nostrils have two small apertures, between which rises a small tentacle. The teeth and tongue are normal. The rounded dorsal is situated between the penultimate and posterior fourths of the back; the two first rays are undivided, the fifth and sixth, the longest, are contained $2\frac{1}{2}$ times in the length of the head, and they equal the extent of the base. The caudal is broad, with the posterior margin rounded; its length $\frac{3}{4}$ of the head. The first undivided anal ray commences opposite the termination of the dorsal fin, which it resembles. The pectorals are broad, rounded; their length is a little less than that of the dorsal. The spines commence immediately behind the upper lip, and terminate a little behind the dorsal, and immediately behind the anal, leaving the tail naked. In form they resemble those of *T. Carduus*. Single individuals, none of which exceeded the length stated, were observed at all seasons at Pinang.

(3887) *Tetrodon bondarus*, Cantor.

Syn. Russell, XXVII. Bondaroo Kappa.

Young. Head above, lips, lower half of the sides and abdomen very pale yellowish olive, minutely dotted with brown; back blackish olive; upper half of the sides brownish olive, with numerous rounded brownish-white spots, many of which are surrounded by a broad black ring, forming a kind of interrupted net-work; inside and behind the pectorals a large black spot, in which a bright yellow oval half-ring, cut by the axilla; a little in front of the pectorals a bright yellow oval spot, half hid by the black gill-cover; on the sides of the head a number of small brownish white spots, and a large black spot like an erect horse-shoe; on the throat a round black spot from whence a widely arched black line ascends to each pectoral; dorsal, anal and pectorals pale brownish olive, minutely dotted with black; caudal darker brownish olive with numerous indistinct whitish spots, and with a broad black band along the posterior margin. Iris bright yellow minutely dotted with black. D 10, C $9\frac{2}{1}$, A 9, P 18, Br. V. Inhabits *Sea of Pinang*, Vizagapatam. The length of the head is contained $4\frac{1}{5}$ times in the total. The eye borders on the profile and occupies nearly the centre of the distance between the muzzle and the gill-opening, but it is on a level above the latter and the pectorals; the greatest diameter, ascending obliquely backwards, is $\frac{1}{4}$ of the length of the head; the distance between the anterior angles of the orbit is $1\frac{1}{2}$ such diameters; between the posterior angles it is two such. There are no nostrils, but in their place appear two lanceolate black tentacula, of which the upper one is the longer, both joined at the base. The teeth and tongue are normal. All the fins are rounded. The first dorsal ray is situated a little behind the commencement of the posterior third of the nody, the caudal not included; the two first rays are undivided; the fifth and sixth, the longest, are contained $2\frac{1}{2}$ times in the head; the extent is $\frac{1}{6}$ less; the distance from the caudal is contained $5\frac{1}{2}$ times in the total length. The anal, [the position of this fin is correctly described by Russell, but his figure represents it in a much too advanced position,] is situated behind the dorsal, which it resembles; its distance from the caudal slightly exceeds $\frac{1}{7}$ of the total. The length of the caudal is $\frac{3}{4}$ of the head; that of the pectorals is a little less than the dorsal. The spines in form and position resemble those of *T. testudineus*, but above they commence from between the eyes. A single young individual was observed at Pinang in May 1844.

Sides smooth without spines.

(3888) *Tetrodon lunaris*, Cuvier.

Syn. Russell, XXIX. Kappa Koorawah.

Tetrodon lunaris, Cuv. R. A. Ed. 1, II. 148 (1).

Tetrodon tepa, Buchanan Hamilton, 10, and 362.

(*Icon.*) Tetrodon leiopleura Gray: Ill. Ind. Zool. I. Pl. 87 Fig. 2, (*Young.*)

Tetrodon lunaris, Ruppell: Neue Wirbelth. Fische, 59.

Physogaster [Physogaster, *Muller*, 1841. "With a hollow papilla in the nasal cavity not however, continued in a tube; lateral margin of abdomen raised into a soft keel from the throat to the tail, corresponding to a second superior keel on the sides of the tail."—*Physogaster* is inadmissible, as it has been applied by Latreille in 1833 to a genus of *Coleoptera*.] lunaris, Muller: Abb. Berl. Akad. 1839, 252 (1).

Tetrodon lunaris, Temm. et Schl. Fauna Jap. Pisc. CXXII. Fig. 1.

Head above and black green olive with a mixture of brownish, lighter on the upper third of the sides; rest of the latter to the abdominal keel, sides of the head and opercles white satin with a broad longitudinal band of shining yellow brass from the eye to the caudal; abdomen milk-white; fins yellow; posterior caudal margin blackish. Iris bright yellow brass-coloured, blackish towards the orbit. D 12, 13 or 14, C $8\frac{2}{1}$, A 11 or 12, P 16, Br. V. Inhabits *Sea and estuaries of Malayan Peninsula and Islands*, Coromandel, Bay of Bengal, Gangetic estuaries, Suez, Japan. Total length: 1 foot. The length of the head slightly exceeds $\frac{1}{4}$ of the total. The eye, bordering on the profile, is situated nearer the gill-opening than the muzzle, above the level of the former and of the pectorals; its longest diameter, ascending obliquely backwards, is $\frac{1}{3}$ of the length of the head. The distance between the eyes equals the diameter. The oval nasal cavity is situated midway between the eyes and the muzzle; each contains two small papillular apertures. The teeth and tongue are normal. The threadlike lateral line commences beneath the posterior part of the nasal oval cavity, descends a short distance nearly vertically, then proceeds horizontally over the upper part of the cheek; opposite the posterior part of the orbit it ascends obliquely to the upper margin of the opercle, between which and the posterior angle of the orbit it gives off a branch which describes an arch over the supraorbital margin. From the upper margin of the opercle the lateral line follows the profile of the back, a little above the lower margin of the spiny portion to a little in front of the dorsal, when it descends obliquely and then continues nearly in the middle of the tail, nearer, however, the soft abdominal keel than the profile of the back, and terminates at the root of the caudal. The soft abdominal keel commences from the throat and proceeds straight along the upper margin of the spiny portion of the abdomen to the lower part of the root of the caudal. The dorsal is situated a little behind the commencement of the posterior third of the

back; the two first rays are undivided; the second, the longest of all, is $\frac{1}{2}$ the length of the head; the posterior margin of the fin is nearly vertical; the extent of the base is $\frac{1}{2}$ of the length of the second ray; the distance from the caudal is contained $4\frac{1}{3}$ times in the total length. The first and only undivided anal ray is placed opposite the posterior half of the dorsal, which it resembles, but the extent is a little less; the distance from the caudal is contained $4\frac{1}{2}$ times in the total length. The upper and lower caudal margins are arched, but the former is a little longer than the latter; the third, or first divided ray from above is the longest, $\frac{3}{4}$ of the length of the head; the posterior margin is concave or crescent-shaped. The pectorals are broad, their posterior margin obliquely truncated; the second upper ray is the longest, $\frac{1}{2}$ of the length of the head. The spines are short, strong, crowded and deeply imbedded in the integuments. Above they commence from the space between the nostrils and terminate a little in front of the dorsal; laterally they extend but very little below the lateral line; on the abdomen they commence from a little behind the throat, are bounded above by the soft keel, and terminate with the anterior half of the body. In the figure of M. M. Temminck and Schlegel in *Fauna Japonica* the spines are represented more distant than they are in the individuals of the Malayan Seas and of the Bay of Bengal, and they appear above to commence from the occiput. In both the latter localities the species is at all seasons very numerous.

(3889) *Tetrodon oblongus*, Bloch.

Syn. Tetrodon oblongus, Bloch. Tab. 146,
Tetrodon oblongus, Shaw, V. 446.
Tetrodon oblongus, Cuv. R. A. Ed. I. 148 (1).
Physogaster oblongus, Muller, l. c.

Young. Head above dark brownish olive with numerous rounded brownish white spots; back and upper third of the sides brownish white, minutely dotted with reddish brown, and with upwards of 11 short dark brownish vertical bands, confluent on the back, and not extending beyond the upper third of the sides; rest of the latter and those of the head pale yellowish buff dotted with reddish brown; abdomen milkwhite; fins transparent yellowish buff, minutely and sparingly dotted with black. D 13, C $8\frac{2}{3}$, A 10, P 17, Br. V. Inhabits *Sea of Pinang*, Indian Ocean. Total length: $5\frac{6}{8}$ inch. The length of the head is a little less than $\frac{1}{4}$ of the total. The eye, bordering on the profile, is situated a little nearer the gill-opening than the muzzle, above the level of the latter and the pectorals; its horizontal diameter is $\frac{1}{4}$ of the head; the distance across the forehead two such diameters. Each nostril has two small papillular apertures. The teeth and tongue are normal. The posterior part of the opercle is naked terminating below in a sharp, downwards pointed angle. The elongated rounded dorsal is situated a little behind the commencement of the posterior third of the back; the anterior four rays are undivided; the sixth and seventh, the longest, are $\frac{1}{2}$ of the length of the head, of which the extent of the base is $\frac{1}{4}$; the distance from the caudal is a little less than $\frac{1}{6}$ of the total length. The anal commences opposite the third dorsal ray; the three anterior rays are undivided; the sixth, the longest, equals the corresponding dorsal; the posterior margin is vertical; the extent of the base is a little less than that of the dorsal; the distance from the caudal equals that of the latter. All three margins of the caudal are slightly arched; the length of the fin is about $\frac{4}{5}$ of that of the head. The pectorals are broad; the posterior margin is a little rounded; the first upper ray, the longest, is contained $2\frac{1}{2}$ times in the head. The very fine hair-like lateral line appears to commence from behind the occiput; at first it follows closely the profile of the back, when it descends obliquely to opposite the last dorsal ray, and then continues in the middle of the tail to the caudal. The abdominal keel is so little raised as scarcely to deserve the name; it commences behind the throat and rises in a low arch towards the pectoral fin, from whence it obliquely descends to a little in front of the anal, and follows the profile of the abdomen to the lower part of the root of the caudal. The spines are short and not very strong, but crowded; above they commence from between the nostrils and terminate a little in front of the dorsal; the opercles, except the posterior part of the opercle, and the abdomen to a little in front of the anus, are spinous; but the cheeks, lips, throat and the posterior part of the body, from between the anus and dorsal, are naked. A single individual was observed at Pinang in January 1844.

(3890) *Tetrodon dissutidens*, Cantor.

Syn. Russell, XXV. II. Kappa *(Young)*.

Crown and sides of the head and back satin reddish brown with purple reflections, lighter on the sides of the body, minutely dotted with reddish brown; back and sides with numerous large rounded spots, dark brownish or olive white; three or four blackish brown vertical bands, indistinct and spotted like the rest, viz. one between the eyes, a second behind the pectorals, surrounding the gill-opening; a third, not constant, between the latter and the dorsal; a fourth from the base of the dorsal; abdomen milk-white; the indistinct abdominal keel in some individuals light yellow; dorsal, pectorals and caudal transparent whitish olive minutely dotted with brown; posterior half of the caudal blackish; anal whitish. Iris bright yellow, minutely dotted with black towards the orbital margin. D 10, C $8\frac{1}{2}$, A 8, P 16, Br. V. In-

Syngnathus biaculeatus, Shaw, V. 453.
Syngnathus biaculeatus, Richardson, Report, 1845, 202.

Head and body pale seagreen: abdomen pale ochre or buff; in the middle of the sides of the rings of the body a large vertically oval spot, lighter than the general colour, edged with very pale vermilion; in some a few black dots, scattered along the sides of the abdomen; fins hyaline. Iris pale silvery green, dotted with brown. D 43 to 45, A 3, 4 or 5, P 21 or 22, Br. IV? Rings of the body 18, of the tail about 55. Total length: 9⅝ inch. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, China Seas, Philippines. The length of the head is contained a little less than 5½ times in the total; the distance from the posterior margin of the orbit to the gill-opening is nearly ¼ of the head; that from the symphysis of the lower jaw to the anterior margin of the orbit exceeds by ⅕ half the length of the head. The diameter of the orbit is ¼ of the length of the head. The distance across the forehead is a little less than one diameter. From the posterior part of the supraorbital margin rises a small, backwards directed thorn, which like the rest of the head is minutely honey-combed. A similar, but smaller thorn appears in the middle of the anterior and posterior margin of the orbit. The opercles are soldered together, and with numerous backwards radiating lines. The occipital crest is surmounted by 3 minute thorns. The body and tail, as far as the dorsal extends, are heptagonal; the rest of the tail is quardrangular, gradually tapering into a point. The greatest vertical diameter, halfway between the head and the dorsal, is about ¼ of the length of the head; the greatest horizontal diameter of the back is contained from 6½ to 7 times in the length of the head, while that of the abdomen varies from 2½ to 3 times in the head. The anus is situated as far behind the middle of the total length as ⅔ of the length of the snout. The dorsal commences on the 18th ring of the body, a little in front of the anus, and continues on the 10 anterior rings of the tail; the extent of the base is one diameter of the orbit shorter than the head; the dorsal and pectoral rays scarcely exceed ⅔ of the diameter of the orbit; the anal rays are about ½. Single individuals occur in the Straits of Malacca during all seasons.

Genus HIPPOCAMPUS, *Cuvier*, 1817. Trunk laterally compressed and conspicuously more elevated than the tail; the junctions of the rings are raised into ridges and their salient angles into spines; caudal none.

(3894) *Hippocampus manmulus*, Cantor. Plate XI. Fig: 1. *Young*. Pale greyish brown; sides and abdominal surface of tail pale yellowish. Length: 3⅝ inch. *Older*. Pale yellowish ochre; fins hyaline; dorsal with two longitudinal series of the blackish spots. Iris silvery bluish-grey. Length: 5 inch. D 19, A 4, P 17, Br.? Rings of the body 11, of the tail 36. Inhabits *Sea of Pinang*. The length of the head is ⅕ of the total; the distance from the symphysis of the lower jaw to the nostril is ½ of the length of the head, of which the diameter of the orbit is ⅓. From the middle of the supraorbital margin rises a small backwards directed spine; the distance between both is less than the diameter of the orbit. From the posterior margin of the orbit radiate numerous lines over the opercles. The occiput carries a crest, surmounted in front by a tubercle, behind by five minute spines; at the root of the pectorals, and on each side of throat appears a small backwards directed spine. The body is heptagonal, its greatest vertical diameter slightly exceeds ½ of the length of the head; the tail is quadrangular, tapering into a point. The anus is situated nearly in the middle of the total length, and opposite the middle of the dorsal. The latter occupies the 10th and 11th ring of the body, and the first of the tail; all three rings are arched, so as to appear like a crest from which the dorsal rises. The length of the rays is a little less than two diameters of the orbit; the extent of the base is ⅔ of the length of the head. The pectorals are a little shorter than the dorsal; the anal is about half the diameter of the orbit. One individual was observed at Pinang in September 1842; a second in January, 1844.

(3895) *Hippocampus comes*, Cantor. Pale XI. Fig. 2. Brownish buff; opercles bluish; round the orbit a few distant brown dots; fins hyaline. Iris silvery white with a number of short brownish lines radiating the pupil. D 16, A 4, P 17, Br.? Rings of the body, 11, of the tail, 33. Total length: 5 inch. Inhabits *Sea of Pinang*. The length of the head slightly exceeds ⅙ of the total; the distance from the symphysis of the lower jaw to the nostril is ⅜; the diameter of the orbit is ⅛ of the length of the head. All the spines of the salient angles are surmounted by oval or rounded tubercles. On the forehead between the eyes appears a single spine; on each supraorbital margin a similar, and between the two a pair of smaller ones; single ones also appear at the anterior and posterior margin of the orbit, and a pair a little beneath the lower margin. The occipital crest is surmounted by three spines, behind which rise five smaller ones forming a cluster like a coronet. At the root of the pectorals appear two, and a pair on each side of the throat. Over the opercles radiate some fine lines. The body is heptagonal; its greatest vertical diameter slightly exceeds the length of the snout to the nostrils. The tail is quadrangular, tapering into a point. The anus is situated nearly in the middle of the total length, opposite the posterior third of the dorsal. The latter occupies the 10th and 11th ring of the body and the first caudal; the length of the rays is 1½ diameter of the orbit, the extent of the base is contained about 3½ times

in the length of the head. The pectorals are a little shorter than the dorsal, and the anal is the shortest of all. A single individual occurred at Pinang in August 1844.

Subclass. SELACHII. Order: PLAGIOSTOMI. Suborder: SQUALI.

Fam. SCYLLIOIDÆ.

Genus SCYLLIUM, (*Cuvier*, 1829,) *Müller und Henle*, 1841. Anterior dorsal between the ventrals and anal; posterior between the anal and caudal; spiracles immediately behind the eyes; gill-openings equidistant: both posterior ones immediately above the pectorals; snout short, blunt; nostrils near the mouth, in some continued in a fissure to the margin of the upper lip; superior nasal valves covering the nostrils, so as generally to leave but a small rounded aperture at the external margin; nasal valves either separated by a larger or smaller piece soldered between their centre, or both united; in some in the middle of the external surface a projection, which occasionally extends beyond the lower margin of the valve; in others at the inferior margin of the nostril a smaller valve covered by the larger; mouth arched; teeth with a central point and one or two on each side; several species with the ventral fins united over the male appendages; scales trifid; oval resembling those of the Rays.

(3896) *Scyllium maculatum*, Müller und Henle.

Syn. Scyllium marmoratum, Bennett: Life of Raffles, 693 ?

(*Icon.*) Scyllium maculatum, Gray: Ill. Ind. Zool. 1. Pl. 98 Fig. 1.

Scyllium maculatum, Muller und Henle: Plagiostomen 5, Taf.

Scyllium maculatum, Richardson: Report, 1845, 193.

(*Young male.*) Ground-colour of the back white, of the sides, vertical fins and upper surface of horizontal fins light slate-blue, with numerous confluent rounded spots, of snuff colour, forming a kind of net-work; near the apex of the two dorsal, of the caudal and anal fins a transversal snuff-coloured band; abdomen, lower surface of pectorals and ventrals and the male appendages bluish white. Iris silvery slate-blue; pupil obliquely linear, black. Inhabits *Sea of Singapore*, Indian Ocean, China Sea, Canton. Total length: 1 foot 7 inch. The anterior dorsal is situated midway between the apex of the snout and that of the caudal; it commences opposite the termination of the ventrals. The posterior dorsal commences at an equal distance from the root of the ventrals and the apex of the caudal. The anal fin commences a little in front of the posterior dorsal, but it terminates before reaching the middle of that fin. The scales are trifid, with a central, flat, pointed keel, and with a minute point on each side. In time the scales become worn and subrhombic. A single young male was taken at Singapore in May 1840. Each male appendage measured 2⅛ inch in length.

Genus CHILOSCYLLIUM, *Müller und Henle*, 1837. Snout blunt; nostrils extending to the mouth; nasal valves separated, each carrying a filament; at the external margin of each nostril a considerable hem-like valve, which continues towards the upper fold of the angle of the mouth; under lip skinny, broad, separated from the throat by a transverse furrow; mouth slightly arched; teeth pointed, with one or two smaller points on each side; spiracles behind and below the eyes; at the posterior margin of each spiracle a projecting tubercle; fourth and fifth gill-opening near each other; dorsal fins placed in front of anal, the anterior dorsal behind the ventrals; pectorals and ventrals rounded, as also the anal and caudal; the anal, without anterior angle, is arched downwards, terminating behind in a point; lower margin of the caudal convex.

(3897) *Chiloscyllium plagiosum*, (Bennett.)

Chiloscyllium plagiosum, Richardson: Report, 1845, 194.

Yu tokay of the Malays.

(*Newborn and very young.*) Ground-colour above white or buff, with numerous black transverse bands, preponderating over the ground-colour, which appears on the head and back like transverse buff bands, each with a transversal brown line in the centre. On the sides and fins the ground-colour is reduced to a number of rounded spots, each with a central brown dot. Lower surface of the body and horizontal fins whitish, of the tail pale blackish. Iris black, with a silvery line bordering the black pupil, which is linear and ascending obliquely backwards. Total length: 4 to 6⅛ inch. (*Older.*) Ground-colour ash-grey or isabella coloured, with (11, 12 or 13) pale brownish black transverse bands, broad on the back, narrower on the sides; the

margins darker than the bands, or with distant dark dots; fins with dark and light spots; abdominal surface whitish. Iris silvery ash-grey or isabella coloured. (Russell, XVI., *Bokee Sorrah.—Scyllium plagiosum*, Bennett.—*Var.* 1, Muller und Henle.) Or: Ground-colour ash-grey or nankin yellow with transverse brownish bands edged with black; within the bands double transverse rows of black dots; single such between the bands; on the sides and fins black rings, each with a central black spot. (*Scyllium ornatum*, Gray—*Var.* 2, Muller und Henle.—*Chiloscyllium plagiosum*, Richardson.—) Total length: 7⅛ to 14⅛ inch. (*Adult.*) Above uniformly ash-coloured or yellowish grey; whitish beneath. Iris silvery, of the ground colour. (*Ra Sorrah*, Russell.—"*Vielleicht eine Varietat*," Muller und Henle.—) Total length: 1 ft. 5 inch to 2 ft. 4 inch. Inhabits *Seas of Pinang, Malayan Peninsula, Singapore*, Indian Ocean, Seas of China and Japan (Richardson), Coasts of Brazil (M. und H.) The anterior dorsal fin commences immediately above the termination of the ventrals; the posterior dorsal commences as far from the anal as the extent of its own base. In young individuals the scales are narrow lanceolate and keeled; in the adult they are tetragonal or subrhombic, with a polished, not keeled, surface. In the young fish appears along the centre of the back a keel composed of scales larger than the rest; on each side, a little below the central keel appears a similar, which borders the upper third of the side. From the root of the ventral fins to the commencement of the anal appears on each side a third keel, which separates the sides from the abdomen. With age the dorsal keel becomes indistinct, but the others appear to vanish. In young individuals the male appendages do not extend beyond the anterior half of the inner margin of the ventral fins; in mature age their length is double that of the inner margin of the ventrals. The livery of the newborn and mature individuals is as constant as that of the intermediate age is liable to variations. The latter, which are but transitory garbs, have been described as constant and distinct varieties by M.M. Muller und Henle. Russell is the only observer who described the mature fish. There appears, however, to exist a constant variety, which is above of a uniform golden bronze colour, paler beneath, with reddish golden fins and with the iris of burnished gold. This Variety is rarely seen in the Straits of Malacca, at Madras [Walter Elliot, Esquire, possesses an adult male of this Variety, measuring 2 ft. 2⅛ inch in length,] and in the Bay of Bengal, as far as the 21st degree. In the Straits of Malacca the species is at all seasons excessively numerous.

Genus GINGLYMOSTOMA, *Muller und Henle*, 1837. (Nebrius, Ruppell) 1837. [Preoccupied by *Nebria*, Latreille, 1802 (*Coleopt*).] Snout blunt: nostrils extending to the mouth, with a short valve at the internal margin, from which proceeds a long cirrus extending to the mouth; a second short valve at the external margin of the nostrils; mouth convex; the folds of the angle of the mouth divided by a deep fissure in an upper and lower fold; the internal extremity of the lower fold separated from the skin of the under lip by a more or less deep, vertical furrow; teeth very numerous, upwards of ten close series, their base rhomboidal, with a central conical apex, with two to four gradually decreasing blunt points on each side; the fifth branchial opening almost hidden in the fourth; both situated above the pectoral fins; spiracles very minute, immediately behind the eyes; anterior dorsal fin opposite the ventrals; posterior dorsal partly in front of, partly opposite the commencement of the anal; the latter fin nearer the caudal than the ventrals, yet not immediately in front of the caudal; the latter with a trace of an inferior lobe; pectoral fins longer than in the rest of *Scyllioidæ*.

(3898) *Ginglymostoma concolor*, (Ruppell.)

Syn Nebrius concolor. Ruppell, Neue Wirbelth, 61, Taf. 17, Fig. 1. Ruppell. Chondropt: 2, Taf. 17 Fig. 2.
Ginglymostoma concolor, Muller und Henle, 22, Taf.

Young. Light brownish buff. Iris silvery light grey; pupil linear, oblique. Inhabits *Sea of Pinang*, Indian Ocean, Massauah (Red Sea). Total length: 2 ft. 5 inch. The anterior dorsal fin commences a little behind the origin of the ventrals, but extends farther back than the termination of the latter. The posterior dorsal commences a little in front of the anal and terminates a little in front of the termination of the latter fin. The scales are broad lanceolate or sub-rhombic with an indistinct central tubercle. The denticulations of the posterior margins are very indistinct, and the scales which are worn down have a polished granular appearance. In the upper jaw appear but three, in the lower four series of teeth, the central apex of which scarcely exceeds the lateral points which gradually decrease. During life the fish carries the tail much more erect than is represented in the figures of M.M. Ruppell, Muller und Henle. The length of the male appendages is less than one-half of the inner margin of the ventral fins. During life this species is distinguished by its beautiful light tint and by its proportions. A solitary young male was taken at Pinang in March 1845. It lived for about two hours in the air. The stomach contained remains of small *Crustacea*. The length of the intestinal canal slightly exceeded ⅓ of the total length of the fish.

Genus STEGOSTOMA, *Muller und Henle*, 1837. Mouth transverse and narrow; at the upper and lower jaw the integuments form two flattened rims, which carry the teeth; the latter

exhibit tripartite laminæ; the centrepiece between the nasal valves is much broader than the valves themselves, and forms a transverse thick rim over the mouth, which above and in front can be covered by this rim. The latter has a rounded free margin in which unite the anterior and posterior surfaces; the posterior, generally hidden, surface is scaly like the rest. The nasal valves are reduced to skinny hems which laterally enclose the central rim. The nasal valves terminate in a strong cirrus. The lower margin of the nostril has no valve. The folds of the angle of the mouth are short; the fossets deep. The head is highly arched and rounded. The cleft between the eyelids is very small, transversely oval, with sharp margins. The spiracles are vertical fissures behind the eye. The fifth branchial opening is hid in the fourth; the third, fourth and fifth appear immediately above the pectoral fins. The anterior dorsal is placed opposite the ventral fins, but extends somewhat in advance; the posterior dorsal is placed between the ventrals and the anal. The latter is placed immediately in front of the caudal. The latter is nearly throughout of uniform height, with the usual incision before the apex, and it is proportionally very elongated.

Stegostoma carinatum, Blyth: Journ. As. Soc. XVI. 725, Pl. XXV. *bis*, Fig. 1. (*Young.*)
Yu tokay of the Malays.

(*Newborn and very young.*) Ground-colour above yellowish white with numerous broad black transverse bands, preponderating over the ground-colour, which on the head and fins is reduced to single rounded or oval spots; lower surface of the body and horizontal fins yellowish white. Iris black with a silvery line bordering the black linear pupil, which ascends obliquely backwards. (Russell, XVIII. *Poollee Makum.* — *Var.* 1, Muller und Henle).—Total length: 12 to 13 inch. (*Older.*) Ground-colour reddish or brownish yellow, more conspicuous than in the newborn, particularly on the fins, where the brown colour is broken up into numerous rounded spots, (on the pectoral fins one or two large rings, with a central spot;) transversal bands reddish brown, with broad snuff-coloured or black margins; in some the bands of the head and body with numerous dark brown rounded spots. Iris like the ground-colour, but silvery. (*Var.* 2, Muller und Henle.—) Total length: 1 ft. 10 to 3 ft.

(*Mature? Adult?*) Ground-colour whitish brown; head from behind the eyes, body and fins with numerous snuff-coloured rounded spots, which are somewhat indistinct on the fins. (*Scyllium heptagonum*, Ruppell.—*Var.* 8, Muller und Henle.—*Stegostoma carinatum*, Blyth.—) Total length: 3 ft. to 5 ft. 7 inch. Inhabits *Sea of Pinang*, Indian Ocean, Bay of Bengal, Jeddah. (Red Sea.) All the descriptions of this species have been taken from young individuals. According to Gmelin it attains a length of about 15 ft. The largest specimen quoted above is a female, collected at Madras by W. Elliot, Esq. The length of the body is 2 ft., of the tail 3 ft. 7 inch. the proportion of the latter is therefore less than in younger individuals, where the tail forms $\frac{2}{3}$ of the total length. The scales are rhombic, with a strong central keel and with 2 to 6 denticulations on each of the two anterior margins. In smaller individuals the scales are broad lanceolate, the central keel terminating in a sharp point, but the posterior margins are either not at all, or indistinctly denticulated. With age the seven raised keels become more distinct. Mr. Elliot has observed this species frequenting the shoals off the coast of Madras feeding on Molluscs. The stomach of several, dissected by him, contained large quantities of molluscous bodies, many of which with the opercula of different species of *Turbinidæ* attached. In a single young female, taken at Pinang in August 1845, the stomach contained remains of small *Crustacea*. Gmelin describes this species as feeding on *Crustacea* and *Testacea*. In a young individual 3 ft. in length, the male appendages did not exceed one half of the internal margin of the ventral fins. The varieties, described by M.M. Muller and Henle, are but individual variations of the infantile livery.

Fam. NYCTITANTIDÆ.

A, without spiracles.

Genus CARCHARIAS, (*Rafinesque*, 1810,) *Muller und Henle*, 1841. Snout flattened, more

or less rounded, moderately long. Nostrils in the centre between the mouth and the point of the snout, or nearer the mouth, at the lateral margin of the snout. Labial cartilage very minute or absent. Ovary of the embryo communicating with a kind of uterine placenta by means of plaited folds. Oviduct either smooth or flocculent.

Sub Genus SCOLIODON, *Muller und Henle*, 1837. Teeth of upper and lower jaw similar, but in the upper jaw appears an old central tooth, trenchant, with the point directed outwards, but not denticulated. The external part of the base forms a blunt protuberance, without or with a slight notch. Posterior dorsal fin placed either immediately opposite the anal, or above the posterior extremity of the latter. A distinct caudal groove above and beneath. Scales, minute, tricarinate. Oviduct of the embryo flocculent.

(3900) *Carcharias* (*Scoliodon*) *acutus*, Ruppell.

Syn. Carcharias acutus. Ruppell : Chondropt. 5, Tab. 18, Fig. 4.
Carcharias (Scoliodon) acutus, M. u. H. 29.
Carcharias (Scoliodon) acutus, Richardson : Rep. 1845, 194.
Yu of the Malays.

Head above, back, sides and fins lead-grey, or light bluish grey; beneath white. Iris light blue silvery, with a narrow silvery line bordering the black linear pupil. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, Indian Ocean, Red Sea, Java, China Seas. Total length : 3 feet. The anterior dorsal fin is situated a little nearer the pectorals than the ventrals ; the upper and posterior margin join in a narrow elongated point. The posterior dorsal commences opposite the posterior half of the base of the anal ; both terminate in elongated points. The distance between the commencement of the ventrals and that of the anterior dorsal equals the distance from the commencement of the ventrals to that of the posterior dorsal fin. The fifth gill-opening is situated above the commencement of the pectorals. The scales are minute rounded, and with five, four or three keels. In young individuals the old central tooth is considerably smaller than the rest. Single individuals occur during all seasons in the Straits of Malacca.

Sub genus PRIONACE, *Cantor*. [πρίων, saw, ἀκή, edge.—Substituted for *Prionodon*, pre-occupied by *Prionodon*, Horsfield, 1823, (*Mam*). The characters given are those of M.M. Muller and Henle.] (*Equivalent to* Prionodon, *Muller und Henle*, 1841). Teeth of either upper jaw, or of both jaws, finely denticulated on both sides, oblique or straight, trigonal, or with a small apex on a broad base. In the upper jaw almost invariably an odd central tooth. Oviduct of the embryo smooth, not flocculent.

(3901) *Carcharias* (*Prionace*) *melanopterus* Quoy et Gaimard.

Ruppell : Neue Wirbelth. Fische. 63.

Head above, back, sides and fins lead-grey, or light bluish grey ; anterior margins of the fins (all the margins of the caudal), and point of the pectorals bluish black ; beneath white. Iris silvery grey with a blackish line bordering the vertically oval pupil. Inhabits *Straits of Malacca*, Red Sea, Waigiou, New Holland, Timor, Java, Sumatra, Madura, China Sea, Japan. Total length : 3 feet. In young individuals the teeth of the upper jaws have denticulated margins, but in the adult they are denticulated in both jaws. The teeth of the lower jaw are smaller and narrower than those of the upper. The anterior dorsal fin commences a little behind the termination of the pectorals ; the posterior commences a little in front of the anal and extends to the posterior third of the latter fin. The points of all three are but moderately elongated. The ventrals commence at the posterior third of the distance between the commencement of the pectorals and the anal. The male appendages are shorter than the internal margin of the ventrals. The fourth and fifth branchial openings are situated above the pectorals. The snout is short and rounded in some, moderately elongated and pointed in others. The scales are minute, with from three to five keels. Single individuals occur at all seasons in the Straits of Malacca.

Genus SPHYRNA, (*Rafinesque*, 1810), *Muller und Henle*, 1841. (Zygaena, *Cuvier*, 1817.) The anterior part of the head broad, flattened and laterally elongated ; nostrils situated at the anterior margin ; eyes at the lateral margins. Nasal valve a small triangular lobe at the internal margin of the nostril. No labial cartilage. Teeth of both jaws similar, resembling outwards pointing flattened pyramids, either trenchant or denticulated, with a section at the external margin of the base ; central teeth in both

jaws. Anterior dorsal nearer the pectoral than the ventrals; posterior dorsal smaller than the anterior, opposite the anal; incision of the caudal fin distinct. Oviduct of the embryos flocculent; ovary not attached to the walls of the uterus.

Zygaena malleus, De Kay: Zoology of New York, IV. 362. Pl. LXII. Fig. 205. (*Young.*)
Sphyrna zygaena, Richardson: Rep. 1845, 194.
Sphyrna tudes. Bleeker: Verhandel. Batav. Gen. XXII. 6.

Foetus. Head above, back sides and fins rosy white, with a greyish tinge along the back; beneath white. Iris silvery light blue; pupil circular black. Total length: 1 ft. $0\frac{7}{8}$ inch. *Young and Adult.* Body and fins slate grey; beneath white. Iris golden. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, Coasts of France, English Channel, Mediterranean, Atlantic, Indian Ocean, Bay of Bengal, Java, Madura, China Seas, Japan, Brasilian Coast, Nantucket, Cayenne, South Coast of Australia. Total length: 10 ft. 9. inch. The anterior dorsal commences immediately behind the termination of the pectorals; the extent of the base is considerably less than $\frac{2}{3}$ of the length of the anterior margin; the upper and the posterior margins join in a narrow, not much elongated point. The posterior, much smaller dorsal commences opposite the root of the anal, but terminates a little before the latter; both fins terminate in an elongated narrow point. The distance from the commencement of the ventrals to that of the pectorals is a little less than the distance between the commencement of the ventrals and that of the caudal. The fourth and fifth branchial openings are placed above the commencement of the pectorals. All the teeth are trenchant, not denticulated; those of the upper jaw appear somewhat broader than those of the lower. The scales are very minute with five or six keels. In the adult the anterior margin of the head forms a nearly uninterrupted or slightly festooned arch till it reaches the nostrils, where there is a more or less deep notch. The posterior margin is nearly parallel to the anterior. The nostrils open near the external part of the anterior margin of the head. From the nostrils proceeds a fissure along the external third of the anterior margin of the head. The length of the head, from the angle of the mouth, is about $\frac{1}{3}$ of the breadth, or a straight line drawn between the eyes. The posterior margin of the head forms with the body an acute angle. Single individuals occur at all seasons in the Straits of Malacca. The largest examined was a female taken at Pinang in January 1845. In her were observed thirty-seven living young, of which

twenty were males, seventeen females. All were of the following dimensions :

Length of the head from the angle of the mouth,	1 5/8 inch.
„ „ lateral margin of the head,	1
Distance between the eyes,	3 3/8
„ from the angle of the month to anus,	4 3/8
„ „ anus to anal fin,	0 7/8
Base of the anal,	0 13/16
Height of do,	0 5/8
Distance from anal to caudal fin,	0 13/16
Length of the caudal,	4
Base of anterior dorsal,	1 3/8
Height of do.	2
Base of posterior dorsal	0 5/8
Height of do.,	0 7/8
Length of pectorals,	1 3/8
Breadth of do.,	0 9/16
Distance between the nostrils,	2 1/8
Distance between the angles of the mouth,	0 9/16

The foetus or very young differs from the adult in its more arched anterior margin of the head, and in the margin itself being more festooned. The length of the head is but little less than one-half of the breadth. From the nostrils proceeds an almost imperceptible fissure, and there is no notch in the anterior margin above them. The posterior margin of the head joins the body at a nearly right angle. (These are the distinguishing characters of *tudes*, Val.) The teeth of the foetus are barely perceptible to the touch. The lateral processes of the head are membranous ; but in each appear two narrow cartilaginous tubes, one containing the optic, the other the olfactorian nerve.

(3903) *Sphyrna blochii*, (Valenciennes.)

Zygaena blochii, Cantor in Ann. and Mag. of Nat. Hist. 1845. (*Adult and Foetus.*)

Spyhrna blochii, Bleeker : Verhand. Batav. Gen. XXII. 6.

Head, body and fins above bluish- or slate-grey ; beneath white or pale yellowish. Iris golden ; pupil circular, black. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore,* Bay of Bengal, Sumatra, Java, Borneo, Celebes, Madura. Total length : 4 ft. 4 inch. In all ages the head is remarkably broad. The breadth of the head is not only liable to slight individual variations, but also to more considerable variations according to age. In the foetus the length of the head, the distance from the angle of the mouth to the anterior margin of the head is about 1/4 of the breadth, or the distance between the lateral margins of the head. With age the length diminishes to about 1/6, which it has been found to be in the largest (adult ?) fish yet examined, a female 4 feet 4 inch in length. The variations will be perceived by the following admeasurements.

	Ft. In	Ft. In	Ft. In.	Ft. In	Ft. In.	Ft. It
Total length	4 4	3 8	2 2	1 11	1 1 5/8	1 1 1/2
Breadth of head.	2 1 1/2	1 9 1/2	0 10 5/8	0 8 3/8	0 6	0 4 7/8
Length of do.	0 3 7/8	0 3 3/8	0 1 7/8	0 1 5/8	0 1 3/8	0 1 1/2

A little more than the central third of the anterior margin of the head forms a large slightly undulating arch. At the termination of this arch appear the nostrils. In the foetus and the young the rest of the anterior margin is directed backwards, and the posterior margin joins the body at an acute angle. But in older individuals the anterior margin of the head, from the nostrils, is not directed backwards, and the posterior margin joins the body at a right angle The fins are placed as they are in *S. zygaena*, except the posterior dorsal which commences but little in front of the terminations of the anal. The following admeasurements were taken from the largest individual, 4 ft. 4 inch in length. She was a female captured at Pinang in September 1844.

Distance between the nostrils,	9 1/8 inch.
„ between the angles of the mouth,	5 2/8

She had eghteen living foetus, of which seven were males, eleven females. The lateral processes of the head were in all bent backwards and towards the sides of the body, so as to make the head resmble a broad arrow, as represented by M. Valenciennes. All the foetus were of the following dimensions :

Total length,	13 4/8 inch.
Length of the head,	1 2/8
„ lateral margin of the head,	0 7/8
Distance between the eyes,	6
„ from the angle of the mouth to anus.	5
„ anus to anal fin,	1 1/8
Base of anal,	0 7/8
Height of ditto,	0 5/8
Distance from anal to caudal fin,	0 6/8
Length of caudal.	4 3/8
Base of anterior dorsal,	1 4/8
Height of ditto,	2 4/8
Base of posterior dorsal,	0 5/8
Height of ditto,	0 4/8
Length of pectorals,	1 6/8
Breadth of ditto,	1 1/8
Distance between nostrils,	2
„ angles of the mouth,	0 7/8

In January 1845 another female occurred,

3 ft. 8 inch. in length, with fifteen living fœtus. Of these ten were males, five females, all of which measured one foot in length. Young individuals, upwards of 3 ft. in length, are very numerous at all seasons in the Straits of Malacca. In the Bay of Bengal, in 21° N., the species is of rarer occurrence. The young feed on crustacea, the older on fishes.

SUB-ORDER RAJAE.

Fam. SQUATINORAJOIDÆ.

Genus PRISTIS, (*Latham*, 1794,) *Muller und Henle*, 1841. (Pristibatis, Blainville, 1828.) Teeth of the saw generally uniform, flattened and trenchant, directed tolerably straight outwards, and commencing in front of the nostrils. Nostrils far removed from the mouth, with a long, narrow triangular valve at the upper margin; at the lower margin a hemlike valve. No cartilages at the angle of the mouth. Mouth transversal, straight. In the upper jaw a membranous transverse vale behind the teeth, with a straight margin. Teeth flattened, like paving stones. Upper eyelid without projection. Spiracles large, separated by a broad bridge from the eyes. Anterior dorsal partly opposite the ventrals. Both dorsals equal. Caudal short, with or without a lower lobe.

(3904) *Pristis semisagittatus*, (Shaw.)

Syn. Russell, XIII. Yahla (*Very young.*)
Squalus semisagittatus, Shaw, V. 361.
Pristis semisagittatus, Cuv. R. A. II 394 (3).
Pristis semisagittatus, Swainson, II. 319.
Pristis semisagittatus Muller und Henle, (*Young,*) 108, Taf. (Mouth and nostrils).
Ikan garagaji of the Malays.

Diluted yellow ochre; beneath whitish. Iris pale golden; pupil black, transversely oval. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Coromandel, Bay of Bengal, Mouths of the Ganges. Total length: 6 ft. 4 inch. The nostrils are situated very near the mouth and extend close to the margin of the snout; from their external angle proceeds a short fissure towards the margin of the snout. The transversal duplicature or valve behind the teeth of the upper jaw has a deep notch at the symphysis of the jaw, and the margin is fringed in young individuals, as described by M.M. Muller and Henle. But in older ones (3 ft. 6 inch. in length,) the margin is smooth. The two dorsal fins are of equal size and form, the superior margin is very concave, and terminates in a narrow elongated point. In young individuals they join at an acute angle. The anterior dorsal commences opposite the termination of the ventrals; the distance from the termination of the posterior dorsal to the commencement of the caudal exceeds by one-half the base of the dorsal. The posterior margin of the caudal is deeply excavated so as to form a lower lobe, but little smaller than the upper. On the tail there is a sharp keel where the abdomen joins the sides; the keel is particularly raised between the posterior dorsal and caudal. The male appendages are styliform and project silghtly beyond the inner margins of the ventrals, to which the anterior two-thirds are joined. The ventrals terminate in an elongated point. The external margin of the pectorals is concave. The anterior branchial opening is situated immediately beneath the commencement of the pectorals, the rest follow an oblique backwards and inwards direction. With the exception of the apex of the male appendages and the teeth of the saw, every other part of the body is covered with minute rounded or irregular scales, of unequal size. The back is rough to the touch in consequence of numerous tubercular scales, a little larger than the rest. All the scales have originally a minute central tubercle which, however, soon becomes worn. In the fœtus the lateral margins of the saw are smooth and not yet pierced by the teeth. At the base the saw is naked to within a considerable distance (from 3 to 5 longitudinal diameters) of the eye. The first two or three teeth on each side of the apex of the saw are placed regularly opposite each other, the succeeding ones are not so. One of the margins carries from 4 to 7 more teeth than the other. The greater number present on one side varies from 25 to 34. In very young individuals, such as have been described by Russell and M.M. Muller and Henle, upwards of 3 ft. in length, each tooth has at the posterior margin a notch which forms a small barb, behind which the base of the tooth becomes narrower. But in individuals of about 4 ft. in length the notch is nearly effaced, and the basal half of the tooth is much broader than the other tapering half, which appears, as if it had been filed. With age the teeth become broad at the base, with trenchant margins tapering to a rounded trenchant point. The anterior margin is arched and slightly directed backwards. The apical half of the teeth is slightly depressed. *Crustacea* form the food of the young, of which single occur in the Straits of Malacca at all seasons. Large individuals are seldom seen.

Genus RHINA, (*Klein*, 1745,) *Muller und Henle*, 1841. Snout rounded; spiracles immediately behind the eyes. Both the superior and inferior nasal valve extend to the inner angle of the nostril. Mouth deeply undulating. Teeth almost globular, not broader than long.

(3905) *Rhina ancylostomus*, Bloch-Schneider.

Syn. Rhina ancylostomus, Bloch-Schneider, 352. Tab. 72.
Rhina ancylostomus, Cuvier, R. A. II. 396 (3)
(*Icon.*) Rhina ancylostomus, Gray: Ill. Ind. Zool. II. Pl. 102, Fig. 2. (Teeth.)

Rhina ancylostomus, Agassiz: Tab. H. Fig. 3, 4. (Teeth.)
Rhina ancylostomus, Owen: Odontogr. Pl. 23 (Teeth.)
Rhina ancylostomus Muller und Henle, 110, (Very young.)
Rhina ancylostomus, Richardson: Report, 1842, 195.

Above earth-brown or deep skyblue; on the back, pectorals and caudal numerous distant whitish spots; beneath white. Iris pale golden: pupil black, transversely oval. Inhabits *Sea of Pinang*, Indian Ocean, Madras, China Sea. Total length: 7 feet. The distance between the nostrils exceeds the length of each nostril by about $\frac{1}{6}$. The distance of the nostrils from the margin of the head is $\frac{1}{3}$ of their length. The horizontal diameter of the eye, which slightly exceeds the vertical, is a little more than $\frac{1}{3}$ of the length of the nostril. The spiracles are nearly ovoid, their longest diameter $\frac{1}{2}$ of the length of the nostrils; their distance from the eye is about $\frac{1}{2}$ of its horizontal diameter. The pectorals, by far the largest of the fins, appear triangular and are nearly equilateral; the anterior convex margin is thickened, rounded and smooth; the posterior is straight and coarsely serrated. The branchial openings in position and form resemble those of *Pristis semisagittatus*. The anterior dorsal commences a little in front of the ventrals and terminates a little before the termination of the latter fins. The base scarcely exceeds one-half of the height of the fin; the anterior margin is convex, the two others nearly straight; the angles are acute. The posterior dorsal is scarcely smaller than the anterior, which it resembles in form; it occupies the centre of the distance between the termination of the anterior dorsal and the commencement of the caudal. The posterior margin of the caudal is deeply excavated, and there is a lower lobe but little smaller than the upper. The caudal keel commences beneath the posterior dorsal fin. The ventrals resemble the anterior dorsal in form and size, but the posterior margin is excavated. The male appendages extend as far as the termination of the base of the posterior dorsal. The outline of the base of each tooth is rhomboidal, with the horizontal diameter slightly exceeding the vertical. The external surface is globular, covered with minute transverse undulating furrows. The largest teeth are situated on the two protuberances of the upper- and the three of the lower jaw. Immediately behind the teeth of the upper jaw, appears a transversal duplicature or valve, with a smooth margin, but with a notch under the symphysis of the jaw. The valve, the palate and the flattened rounded tongue are all covered with scales like those of the rest of the body. They are very minute and consist of a triangular keel, rooted in the integuments, but projecting beyond them in an oblique backwards direction. Near the point the keel expands and presents a minute rhomboidal surface, so that the entire scale resembles the arm of an anchor with its fluke and peak. In many places the scales are worn down, become smooth and granular, and lose their original form. Larger and different scales are distributed in regular conspicuous crests. Of the latter there are two of on oval shape, placed obliquely, a little in front of and higher up than the eyes. Immediately behind this pair commences a second, each of which borders the supraciliar margin, and extends a little behind the upper margin of the spiracle. From each of the supraciliar crest proceeds a smaller narrower one downards, bordering the anterior part of the orbit. From the centre between the supraorbital crests commences the dorsal, the longest of all, which extends to opposite the termination of the pectorals. Each scapular region carries a superior and an inferior crest, both of which are narrow and placed parallel to the dorsal crest. The superior is $\frac{1}{3}$, the inferior $\frac{1}{6}$ of the length of the dorsal crest. A very short crest appears at the lower circumference of each spiracle. The crests are composed of single scales larger than the rest. All have a polygonal base from which rises a compressed thorn, from the apex of which numerous furrows radiate towards the base of the sides. On the snout, above and beneath, appear a number of pores. Opposite the spiracles, a little in front of the dorsal crest, the integuments are pierced by two large pores, placed side by side. The distance between these two is about one half of the distance from each to the nearest supraorbital crest. The following dimensions were taken from a male, measuring 7 ft. in length.

Distance from the apex of the snout to the mouth,	0 ft.	$6\frac{3}{8}$ inch.
„ from the mouth to the middle between the terminations of the pectoral fins, ...	1	6
„ from thence to the anus, ...	1	0
„ from the anus to the caudal, ...	2	$3\frac{3}{8}$

Breadth of the mouth, ...	0	7
Length of the supraorbital crests, ...	0	$8\frac{1}{8}$
„ of the dorsal crest, ...	1	4
Greatest diameter of the nostril, ...	0	$4\frac{5}{8}$
„ of the eye, ...	0	$1\frac{3}{8}$
„ of the spiracle, ...	0	$2\frac{1}{8}$

The description of M.M. Muller and Henle is taken from a very young individual. During four years three solitary individuals occurred at Pinang. According to Lord Arthur Hay and Mr. Walter Elliot they are of more frequent occurrence at Madras. Mr. Elliot, who has observed the habits of the fish, describes it as hugging the shore, moving slowly along the bottom. Hence the Tamil name: "*Mann Ulavi*," i. e. "Mud-skate." In some dissected, Mr. Elliot

observed fragments of *Crustacea* in prodigious quantities.

Genus RHYNCHOBATUS, *Muller und Henle*, 1839. Snout elongated, acute, with a tapering keel along the middle. The interval between the keel and the inner margin of the pectorals is membranous; spiracles immediately behind the eyes. Upper eyelid with a simple projection. Upper and lower nasal valve extend but halfway to the internal angle of the nostril; outside in front, at the upper margin of the nostril is a narrow hem. The undulations of the snout, particularly the lateral ones, are shallow. Teeth broader than long, with a transversal protuberance. A transversal arched row of pores on the abdominal surface of the scapular region.

(3906) *Rhynchobatus djeddensis*, (Forskal.)

Rhinobatus duhamelii, Blainville: Faune. Fr. 148.
Rhinobatus laevis, Swainson, II. 322.
Rhynchobatus laevis, Mulier und Henle, 111.

(*Young.*) Above light greenish olive, pale yellowish- or reddish brown, with a downwards arched black band on the upper eyelid; a small black spot on each side of the point of the snout; a large oval black spot surrounded by several white (from 3 to 6) ones above the middle of the base of the pectorals, and with more or less numerous white spots on the pectorals and the sides, where in some they are disposed in longitudinal lines; sides of the snout, pectorals and ventrals in some tinged with carmine; beneath whitish. Iris golden; pupil transversely oval, black. (Bloch-Schneider.—Russell, X.—*Var.* 2, Muller und Henle.) *Var.* 3. Muller und Henle.—With numerous round spots on the snout, head, back, tail and pectorals. (*Rhinobatus djeddensis*, Ruppell.) (*Adult.*) Either uniformly coloured, or with indistinct spots; but without spots at the point of the snout, and without bands on the upper eyelid. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Indian Ocean, Bay of Bengal, Red Sea. Total length: 5 feet. Spiracles with two denticulations at the posterior margin. The length of the snout is a little less than $\frac{1}{7}$ of the total. The distance of the nostril from the lateral margin is $\frac{1}{4}$ of the length of the nostril. The distance between the anterior extremities of the nostrils is double the length of each nostril; the distance between the posterior extremities is a little less than the length of each nostril. The anterior dorsal commences a little behind the commencement of the ventrals, and extends a little farther back than the latter. The extent of the base is less than one half of the anterior margin. The posterior dorsal is smaller; its distance from the caudal is a little more than one half of the distance from the anterior dorsal. Both dorsals are similar, terminating in an attenuated point, but the posterior is much the smaller. The extent of their base is less than one half of their anterior margin. The pectorals appear triangular. The ventrals terminate in an attenuated point, which extends to the opposite point of the anterior dorsal. The posterior margin of the caudal is very concave; the lower lobe but little smaller than the upper. The lateral keel commences a little above the termination of the ventrals. The scales are very minute subrhomboidal or orbicular and imbricated; they carry from 3 to 6 keels. A number of small recurvous spines are at intervals distributed in lines. One such, the supraorbital, surrounds the anterior part of the orbit, and extends backwards to above the spiracle. Another, the dorsal, extends along the spine to the posterior dorsal. As in *Rhina ancylostomus*, there appear two conspicuous pores a little in front of the dorsal line. In young individuals these pores are less distinct. A little behind the occiput, on each side, appears a short backwards diverging line of spines. Each shoulder carries a second, a little longer, also directed backwards. In large individuals there is another line beneath the scapular. It consists but of two or three spines. The following dimensions were taken from a female 4 ft. $1\frac{6}{8}$ inch in length.

From the snout to the mouth,	0 ft.	$8\frac{5}{8}$ inch.
From the mouth to the anus,	1	3
From the anus to the caudal,	1	6
Length of the caudal,	0	8
Distance between the anterior angles of the pectorals,	1	$3\frac{1}{8}$
From the snout to the eyes,	0	$7\frac{5}{8}$
Distance between the orbits,	0	$2\frac{1}{8}$
„ between the internal angles of the nostrils,	0	$1\frac{7}{8}$
Breadth of the mouth,	0	8
From the point of the snout to the end of the base of the pectorals,	1	$6\frac{4}{8}$
Greatest breadth of the keel of the snout,	0	$1\frac{5}{8}$
Distance between the dorsals,	0	9
„ between the posterior dorsal and caudal,	0	$5\frac{4}{8}$
„ between the pectorals and ventrals,	3	

Single individuals occur at all seasons in the Straits of Malacca.

Genus RHINOBATUS, (*Bloch-Schn.* 1801)

Muller und Henle, 1841. Skull elongated in a keel, the interval between which and the internal margin of the pectorals is membranous; snout more or less pointed. The upper nasal valve consists, as in *Rhynchobatus*, of an external narrow elongated lobule, and an internal which is broader and shorter. The external lobule is narrow, but its rounded apex extends to the lower margin of the nostril, and does not project at an angle from the inner lobule. The external lobule is situated nearly in the middle of the upper margin of the nostril; the internal lobule extends more or less inwards. The lower nasal valve extends from the external angle more or less inwards. Spiracle and eye surrounded by a common fleshy wall. The upper eyelid carries in the centre a projection. The valve of the upper jaw has a fringed margin and is notched in the centre. The anterior part of the lateral margin of the disk has two slight undulations.

Subgenus RHINOBATUS, *Muller und Henle*, 1841. The upper nasal valve does not extend to the inner angle of the nostril.

(3907) *Rhinobatus* (*Rhinobatus*) *ligonifer*, Cantor. Plate XIV. (*Young?*) Keel of the snout, head, body and fins above greenish ash-grey; snout and abdominal surface white. Iris pale golden of the general colour; pupil broad cordate, black. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*. Total length: 1 foot $4\frac{6}{8}$ inch. This species greatly resembles *Rhinobatus thouini*, [*Raje thouin*, Lacep. I. Pl. 1, Fig. 3-5.—*Raja thouiniana*, Shaw: V. 318. *Pl.* 147.—*Rhinobatus thouin*, Cuv. R. A. II. 396. (2).—*Rhinobatus* (*Rhinobatus*) *thouini*, M. und H. 120.] but differs from the latter as described by M.M. Muller and Henle, in the following characters. The lateral margins of the snout, a little from the apex are deeply bent inwards, and near the apex they are similarly, but less distinctly, bent a second time. The apex thus somewhat resembles the figure 8. The keel is not smooth, but covered to the very point with small distant recurvous thorns, like those of the rest of the upper part of the body. The shallow furrow of the keel extends considerably in front of the eyes. Each spiracle carries two distinct denticulations. The pectinations of the nostrils vary from 85 to 90, (in *R. thouini* about 60). The teeth vary from 75 to 80 in a series (in *R. thouini* about 60). The scapular region carries an outer-, and a larger inner thorn. In *R. thouini* the inner thorn is the smaller of the two. The keel is most contracted a little in front of the eyes, the breadth being about $\frac{1}{15}$ of the length. From thence it slowly widens towards the 8-shaped apex, which is about $\frac{1}{4}$ of the length of the keel. The shallow lanceolate furrow commenees between the eyes and extends as far beyond them as the basal sixth of the keel. The posterior margin of the spiracle carries a smaller internal, and a larger external denticulation. The distance between the nostrils is one half of the length of each nostril, and it slightly exceeds the distance between the lateral margin of the head and the nostrils. The upper nasal valve extends as for as the inner third of the margin. The distance between the orbital thorns exceeds by $\frac{1}{3}$ the length of the orbit and spiracle together. The pectoral fins are rounded. The ventrals are subrhomboidal, terminating in an acute point; the male appendages are somewhat shorter than the inner margins. The posterior dorsal is very little larger than the anterior. The lateral keel commences a little behind the ventrals. The upper surface of the snout, body and fins is covered with small distant scales. They are all directed backwards, and resemble those of *Rhina ancylostomus*. The keel of the snout and the upper surface of the head are covered with minute thorns. Three to five larger thorns border the anterior margin of the orbit; two the inner margin of the spiracle. The largest thorns are placed at intervals along the spine of the back, and the line extends as far as the posterior dorsal fin. In front of the dorsal series appear two pores, as in *Rhina ancylostomus*. In each scapular region appears an isolated thorn, and outside of that a second smaller one. The thorns are all compressed, with a broad oval base with radiating lines. The lower surface of the snout is covered with minute somewhat distant scales, which are triangular, with the apex directed backwards. Those of the rest of the lower surface are nearly round, with an indistinct central tabercle. The abdominal surface of the scapular region is on each side marked by an undulating linear furrow. The cavity of the mouth and the large flattened tongue are covered with minute triangular scales. The membranous valve behind the teeth of the upper jaw has a large notch in the centre and a smaller one at each angle of the mouth. The margins of the smaller notches are fringed. The following dimensions were taken from a female 1 ft. $4\frac{6}{8}$ inch in length.

From the snout to the internal angle of the nostril,	$3\frac{6}{8}$ inch.
From thence to the mouth,	$0\frac{2}{8}$
From the mouth to the anus,	$3\frac{2}{8}$
From the anus to the point of the caudal,	9
Distance between the nostrils,	$0\frac{4}{8}$
Length of the nostrils,	1
Breadth of the mouth,	$1\frac{2}{8}$
Greatest breadth of the disk,	$5\frac{3}{8}$
Distance from the ventrals to the anterior dorsal,	$1\frac{6}{8}$
„ between the dorsals,	$1\frac{4}{8}$
„ between the posterior dorsal and the caudal,	$0\frac{6}{8}$
Length of the caudal,	$2\frac{2}{8}$

Solitary individuals occur during all seasons in the Straits of Malacca.

PLATYRHINA [Pre-occupied by *Platyrhinus*, Clairville, 1798. (*Coleopt.*)] SINENSIS, Muller und Henle, occurs, but rarely, at Singapore and Pinang.

Fam: TORPEDINIDÆ.

A. With two dorsal fins.

Genus NARCINE, *Henle*, 1834. Disk orbicular, elliptical or angulated, rounded in front and provided with a broad keel. Mouth small, protractile, surrounded by a circular skinny fold, which terminates above in the frænulum ["Bändchen"] of the nasal valve. Nasal valve straight, with a central projection, and sometimes with the lateral projections slightly elongated, making the valve trifid. A labial cartilage above and beneath. Teeth in quincunx, with a point in the middle. They project beyond the margin of the jaw like an elliptical plate. The lips not fixed to the jaws, but moveable. A membranous valve behind the upper jaw. Tail longer than the disk. The anterior dorsal behind the ventrals, smaller than the posterior. Spiracles immediately behind the eyes. Margins of the spiracles smooth.

(3908) *Narcine indica*, Henle.

Narcine indica, Henle : Narcine, 35, Taf. II. Fig. 2.
Narcine indica, Muller und Henle, 130.
Pari kubbas of the Malays.

Body and fins above light reddish brown or copper-coloured, with numerous larger and smaller chocolate-coloured spots, in young individuals broadly edged with silvery white. The spots generally circular, some oval, others confluent. Beneath whitish. Iris narrow golden; pupil triangular, with the apex downwards, black; margins of the spiracles flesh-coloured. Inhabits *Sea of Pinang*, Tranquebar. Total length: 1 ft. 6 inch. The disk has a pentagonal appearance and is but very little broader than long. The tail is slightly longer than the body. In very young individuals it is a little shorter than the body. The ventrals are not covered by the pectorals; their angles are acute, their anterior margin slightly concave. The male appendages project but slightly beyond the inner margin of the ventrals. The anterior dorsal commences opposite the termination of the ventrals. In the young the apex forms an acute angle, later it becomes rounded. The extent of the base is $\frac{1}{2}$ of the length of the anterior margin. The distance between the two dorsals equals that between the posterior and the caudal. Both dorsals are of similar form and size. The posterior margin of the caudal is very convex. The following dimensions were taken from a female, measuring $11\frac{1}{8}$ inches in length.

From the snout to the mouth, ...	$1\frac{6}{8}$ inch.
From the mouth to the anus, ...	$3\frac{6}{8}$
From the anus to the point of the caudal.	$5\frac{3}{8}$
Length of the disk....	$5\frac{2}{8}$
Breadth of the disk, ...	$5\frac{4}{8}$

Large individuals are at Pinang of rare occurrence, but younger, from 3 to 6 inches in length, are taken at all seasons. In or out of water they may be handled with impunity. Several species of fishes introduced in a jar filled with sea-water and containing a large *Narcine* shewed no consequences from the contact, nor did they appear to avoid the Torpedo. The food of this and the other Malayan *Torpedinidæ* consists of *Crustacea* and *Testacea*.

B. With one dorsal fin.

Genus ASTRAPE, *Muller und Henle*, 1837. Snout short without keel, generally similar to that of *Narcine*. Frænulum of the nasal valve with a cylindrical cartilage. Teeth pointed with a tetragonal base, but slightly projecting beyond the margin of the jaw. A membranous valve in both jaws. The solitary dorsal and the caudal rounded. Eyes close to the spiracles. The latter smooth.

(3909) *Astrape dipterygia*, (Bloch-Schneider.)

Syn. Raja dipterygia, Bloch-Schneider, 359.
Torpedo dipterygia, Var. Olfers. Torp 25.
Narcine dipterygia, Henle: Narcine: Taf. III. Fig. 2.
Astrape dipterygia, Muller und Henle: 131. (*Young.*)
Pari kubbas of the Malays.

Above dark greenish olive, with a large round whitish spot on each side at the posterior margin of the disk; anterior half of the ventrals whitish: a large round whitish spot on each side above the termination of the ventrals, a similar one on each side of the root of the caudal; dorsal and caudal blackish brown or black; beneath whitish. Iris golden; pupil circular black. In the very young (upwards of $4\frac{3}{8}$ inch in length) the ventrals are of a uniform colour like the ground-colour. Inhabits *Sea of Pinang, Malayan Peninsula, Lancavy Islands, Singapore*, Tranquebar. Total length: 8 inch. The disk is rounded, and as broad as long. It covers the anterior margin of the ventrals. The latter are tetragonal, with acute angles in the young, but later they become obtuse. The male appendages are strong and extend to opposite the termination of the dorsal. The latter commences at the posterior third of the length of the fish. The eyes are much smaller than the spiracles. The following dimensions were taken from a male $6\frac{1}{8}$ inch in length.

Length and breadth of the disk,... ...	3 inch.
From the snout to the mouth,... ..	$0\frac{5}{8}$
From the mouth to the anus, ...	$2\frac{2}{8}$
From the anus to the apex of the caudal,	$3\frac{2}{8}$

Single individuals occur in the Straits of Malacca at all seasons.

C. Without dorsal fins.

Genus TEMERA, *Gray*, 1831. ["Snout, mouth and membranous valve of the jaws as in *Astrape*. Tail without dorsal fin, short in proportion to the disk. Spiracles immediately be-

hind the eyes, smooth. Teeth flattened." (*Muller und Henle*, page 131.)] Body orbicular; ventral fins large, produced, nearly square; tail very short, and compressed, finned; dorsal fin none; most nearly allied to *Torpedo*, but differs in having no dorsal fin, in which character it is most nearly allied to *Narke* of Caup, a genus not noticed by Cuvier, which has only one dorsal fin, while *Torpedo* has two.

(3910) *Temera hardwickii*, Gray.

Plate XII, Fig. 1-2.

(*Icon.*) Temera hardwickii, Gray: Ill. Ind. Zool. II. Pl. 102. (*Young.*)

Temera hardwickii, Muller und Henle, 131, Taf. Fig. 1, (Mouth and Teeth.)

Pari kubbas linchin of the Malays.

Above light yellowish brown; margins of spiracles flesh-coloured; whitish beneath. Iris golden; pupil transversely oval, black. In some the disk and tail above have large irregular white patches. (*Var.* 2. M. und H.) Inhabits *Sea of Pinang, Malayan Peninsula, Singapore.* Total length: 1 ft. 6 inch. The disk is nearly round, but the snout between the eyes appears truncated. The relative proportions of the length and breadth appear to be liable to slight individual variations. In some the disk is a little longer than it is broad, in others vice versâ. The eyes are as large as the spiracles. The ventrals are not covered by the pectorals. The following dimensions were taken from a female $4\frac{1}{8}$ inch in length.

From the snout to the mouth, ...	$0\frac{3}{8}$ inch.
From the mouth to the anus, ...	$2\frac{1}{8}$
From the anus to the point of the caudal, ...	$1\frac{5}{8}$
Length of the disk, ...	$2\frac{3}{8}$
Breadth of the disk,...	$2\frac{4}{8}$

She had four foetus, each $1\frac{1}{8}$ inch in length, in colour and form resembling the mature fish. But the vertical diameter is in the foetus proportionally greater. In the Straits of Malacca this species is at all seasons very numerous. The electric organs (Pl. XII. Fig. 1, *a. a.*) are of an elongated tetragonal arched form, and occupy the sides of the disk. They occupy the space between the snout and the abdominal cavity, their internal concave margin bordering the branchial apertures. The length of each is a little more than $\frac{1}{3}$ of the length of the fish, and each occupies a space about double that of the abdominal cavity. Each organ is composed of a number of pentagonal or hexagonal cells, filled with a transparent colourless fluid. The anterior and external margins are surrounded by a bundle of cartilaginous fascicles (*b.*) outside of which appears a long cutaneous nerve (*c.*) from which proceed at right angles a number of small branches towards the external margin of the pectoral fins. The abdominal cavity (*d.*) is remarkably reduced. The intestinal canal, from the entrance of the Ductus coledochus, measures $\frac{1}{4}$ of the total length of the fish. The liver consists of two large, elongated lobes. Beneath the anterior part of the right lobe appears the small oval gall-bladder. The small linear spleen is attached to the major arch of the stomach, close to the pylorus. Plate XII. Fig. 2 represents the brains, viewed from above. Immediately behind the spiracles (*a.* the left,) appear two branches of *Trigeminus*. The anterior (*b.*) proceeds along the anterior margin of the electric organ, the posterior (*c.*) also supplies the anterior part of the organ. The posterior part of the organ is supplied by two very large branches of *Pneumogastricus* (*d. e*). Many of these fishes are infested by minute *Entozoa*. They occupy the cellular tissue immediately beneath the integuments of every part of the body, the electric organs not excepted. It is a *Cysteocercus*, barely perceptible to the naked eye.

(3911) *Cysteocercus temerœ*, Cantor. (Pl. XII. Fig. 3.) Of a pyriform shape. From the oval bladder proceeds the conical, elongated neck, which terminates in a pore, surrounded by recurvous spines. The colour is hyaline with numerous brownish dots; the cavity of the bladder is pale greenish. The figure is magnified, as it appeared under $\frac{1}{20}$ single lens.

Fam. TRYGONISIDÆ.

A. Tail without spine.

Genus RHACHINOTUS, *Cantor.* [Ῥάχος thornbush; νῶτος back. Substituted for *Anacanthus*, Ehrenberg, 1837, pre-occupied by *Anacanthus*, Gray, 1831, (*Pisc.*) and *Anacanthus*, Serville 1832, (*Coleopt.*)] (*Equivalent to* Anacanthus, *Ehrenberg*, 1837.) Teeth flattened. Tail without radiated fin, but with a skinny hem beneath, or naked.

(3912) *Rhachinotus africanus*, (Bloch-Schneider.)

Syn. Raja africana, Bloch-Schneider, 367.
Anacanthus africanus, Muller und Henle, 157.

Above greenish white; beneath white. Iris golden greenish; pupil triangular, black. Inhabits *Sea of Pinang*, Guinea, Red Sea. The disk is rounded, a little narrower towards the tail than towards the slightly projecting pointed snout. A space about 4 inches in breadth, comprising the snout, forehead and the pectoral fins, is free from scales, but sparingly covered with distant thorns. The latter, of which none exceed $\frac{1}{8}$ inch in height, stand erect on a rounded or oval radiated base. The head from between the eyes, the back and the anterior two-thirds of the tail, (the latter above and beneath,) are thickly covered with small heart-shaped scales. Their surface is smooth, obliquely raised towards the apex, which is gene-

rally directed inwards to the mesial line of the body. Their margin is abrupt, with three or four concentric lines or strata. Between the scales are scattered a number of single thorns, the longest of which are about $\frac{3}{16}$ of an inch. Their base is stellate, with three to five roots fitting into the intervals between the nearest scales. The thorns are generally erect, but those of the posterior part of the back and of the tail are directed slightly backwards. On the upper part of the anterior fifth of the tail the thorns cease. The tail is compressed, gradually tapering to a narrow point, and densely covered with scales as far as the posterior third, where they become few and far between. The abdominal surface of the tail, as far as the thorns extend, is broad, convex; the rest is acute and presents a naked, indistinct, skinny hem. The abdominal surface of the body is smooth, naked.

Length from the point of the snout to the mouth,.....	0 ft.	$2\frac{6}{8}$ inch.
From the mouth to the anus,	1	$0\frac{5}{8}$
From the anus to the apex of the tail, ...	1	$7\frac{1}{8}$
Distance between the eyes, ...	0	$2\frac{5}{8}$
Greatest breadth of the disk,	1	4

A single female occurred at Pinang in Dec. 1843.

Genus TRYGON, (*Adanson*), *Muller und Henle* 1841. Disk oval or rhombic; tail as long as the body or longer, without hem, or with hems not extending to the apex. Mouth a little arched. Teeth with a central point or transversal tubercle, which in some is rough, with a more or less distinct transversal furrow in front and behind; the furrow of the lateral teeth becomes more distinct. The whole surface is more or less wrinkled. Membranous valve of the upper jaw with a straight, deeply fringed margin; a second posterior valve deeply notched. In the lower jaw behind the teeth appear generally several papillæ.

A. Tail without fin.

(3913) *Trygon uarnak*, (Forskal).

[* M.M. Muller and Henle, quote as synonymes: "Trygon uarnak, } Ruppell, Atlas, p. 51." "Trygon omeschcrit. }
The quotation, which has been repeated by Sir John Richardson, l. c., is a mistake. The two names occur neither in page 51. nor in the "Alphabetisches Verzeichniss" of Dr. Ruppell's Atlas.]

Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Indian Ocean, Red Sea, Bay of Bengal, Mouths of the Ganges, China Sea, Cape of Good Hope. (*Young*). Body above light redddish brown or greenish-olive, with numerous black spots, between which the ground-colour appears like a network; beneath whitish; tail brownish white with numerous black rings or transversal bands. (Disk 6 to 9 inch. broad.—*Var.* 2 and 4, M. u. H.) (*Older*). Brownish- or greyish- olive with numerous whitish spots; posterior part of tail in some with indistinct blackish or whitish rings. (Disk 3 ft. broad.—*Var.* 3, M. u. H.) (*Adult*). Uniformly brownish- or greenish- olive. Iris golden; pupil transversely oval. In the very young individuals the eyes are very prominent and project above the level of the spiracles. The skin is naked, and in the centre of the back appears but a single heart-shaped white tubercle. In a spotted individual, 9 inches broad, there is a second smaller heart-shaped tubercle behind the former, and the head and the sides along the spine of the back are scantily covered with minute distant heart shaped scales, which on the root of the tail are placed in a double longitudinal series. On the tail appear numerous very minute, distant thorns, which later disappear. In older individuals (upwards of 3 feet broad), the head, back and sides and the anterior half of the tail are covered with smooth orbicular scales, the intervals between which are filled with many smaller than the rest. The disk is a little broader than long. The distance from the point of the snout to the centre between the nostrils exceeds by one third the distance between the nostrils. The snout is more prominent in the young than in the adult. The tail is compressed towards the spine, the rest cylindrical, tapering to a thin point. Its length is about four times that of the body. On the lower surface appears a very indistinct skinny hem. The spine is situated at the termination of the anterior seventh or ninth of the tail. Its length is liable to considerable individual variations. The following dimensions were taken from a young male, (*Var.* 3, M. u. H).

From the snout to the mouth,	0 ft.	$3\frac{4}{8}$ inch.
,, mouth to the anus,.....	1	$0\frac{4}{8}$
Length of the tail,.....	5	$3\frac{5}{8}$
Greatest breadth of the disk,.	1	$10\frac{4}{8}$
Distance between the nostrils,	0	$1\frac{4}{8}$
,, ,, eye,.....	0	3

Distance from the snout to the eyes,	0 ft.	$3\frac{4}{8}$ inch.
Breadth of the mouth,	0	$1\frac{5}{8}$

Young individuals of this species are numerous at all seasons in the Straits of Malacca, but larger ones, with the body about 4 feet in length, are uncommon.

(3914) *Trygon imbricata*, (Bloch-Schneider).

Russell, IV. Isacurrah Tenkee. (*Very young.*)
Cuv. R. A. II. 399 (3).
Trygon imbricata, Muller und Henle, 164.
Trygon imbricata, Bleeker: Verh. Batav. Genoots. XXII. 6.

Above lighter or darker brown; the tail in some lighter than the body; beneath white. Iris golden; pupil transversely oval. Inhabits *Sea of Pinang, Singapore, Malayan Peninsula*, Bay of Bengal, Java, Madura. The snout is acutely pointed; the disk is of equal length and breadth; the external and the posterior angle of the pectorals are rounded. The distance between the nostrils is less than one half of that from the snout to the centre between the nostrils. The tail is but little longer than the body. The head from between the eyes is covered with minute, somewhat distant scales. They are heart-shaped, of unequal size, with the apex directed towards the snout. On the back appears an irregularly oval patch of similar scales, with their points directed towards the tail. Between the occiput and the scapular region appear a series of single scales, larger than the rest. The anterior fourth of the tail is compressed and above covered with scales like those of the back, with a mesial line of distant lanceolate scales, which gradually increase in length towards the two spines. The anterior of the two spines is situated at the termination of the anterior fourth of the tail. It is a little shorter than the posterior, which is situated a little more backwards, and is about $\frac{1}{4}$ of the length of the tail. Behind the two spines the tail is naked and becomes very slender and tapering. Beneath it appears a very indistinct trace of a skinny hem. Single small individuals occur at Pinang at all seasons.

Breadth of the disk,	$5\frac{1}{8}$ inch.

(3915) *Trygon zugei*, Bürger.

Syn. Trygon zugei, Muller und Henle, 165. Taf.
Tyrgon zugei, Richardson: Report, 1845, 197.

(*Young.*) Above brownish yellow; caudal membranes black; beneath reddish white. Iris golden; pupil transversely oval. Inhabits *Sea of Pinang*, Indian Ocean, Sea of Japan, China. The snout is very prominent, acute. The anterior margins of the disk are straight, the posterior convex. The external angle of the pectorals is equidistant from the apex of the snout and the anus. The length of the disk slightly exceeds the breadth. The distance between the nostrils and the apex of the snout is contained $3\frac{1}{2}$ times in that between the apex and the centre between the nostrils. The distance between the eyes is $\frac{1}{3}$ of their distance from the point of the snout. The teeth have a transversal keel. The thin tapering tail is double the length of the body. The spine is situated nearly at the anterior fourth of the tail. Behind the spine appear a superior and inferior membrane. Both are low, the inferior longer than the superior. The body is naked, but on the dorsal column, between the occiput and the scapular region, appear 3 distant small thorns. Some distant, very minute thorns appear on the sides of the tail behind the spine. The latter is about $\frac{1}{6}$ of the length of the tail.

From the apex of the snout to the mouth,	$1\frac{7}{8}$ inch.
„ mouth to the anus,	$2\frac{2}{8}$
Length of the tail,	9
Distance between the nostrils,	$0\frac{7}{16}$
Greatest breadth of the disk,	$4\frac{2}{8}$
Distance between the eyes.	$0\frac{5}{8}$
Breadth of the mouth	$0\frac{7}{16}$

Single young individuals occur at Pinang but rarely.

Genus PTEROPLATEA, *Muller und Henle*, 1837. The disk is nearly or more than twice as broad as long. Tail short, generally shorter than the body, naked or with low fins. Mouth slightly arched. The teeth do not extend to the angles of the mouth; they carry one to three points. The upper membranous valve of the jaw is indistinct, without fringes. No papillæ in the lower jaw. The skin is smooth, or covered with tubercles.

(3916) *Pteroplatea micrura*, (Bloch-Schn.)

Syn. Trygon micrura, Bloch-Schn. 300.
Russell, VI. Tenkee Kunsul. (*Young.*)
Raja poecilura, Shaw, V. 291.
Trygon kunsua, Cuvier, R. A. II. 400(4)
Trygon poecilurus, Bennet: Life of Raffles, 694.
Pteroplatea annulata, Swainson, II. 319.
Pteroplatea micrura, Muller und Henle, 169.
Pteroplatea micrura, Richardson, Report, 1845, 197.

(*Very young.*) Above reddish- or bluish- brown, with numerous dark dots, or with distant indistinct light spots; beneath bluish- or reddish- white. (*Older.*) Above bottle-green, or bluish-brown; tail with black and white or rose-coloured rings;

beneath whitish. Iris golden, pupil transversely oval. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Bay of Bengal, Mouths of the Ganges, Red Sea, Sumatra, Java, Borneo, China Sea. The snout is little prominent. The anterior margin of the pectorals is a little longer than the posterior and slightly concave in the middle; the posterior is convex; the external angle is conical, the posterior obtusely rounded. In younger individuals the length of the disk, from the snout to the anus, is less than one half of the breadth of the disk, or the distance between the external angles of the pectorals. In older individuals the length is $\frac{3}{4}$ of the breadth of the disk. The distance between the inner angles of the nostrils is about one half of the greatest diameter of the nostril. The distance between the external angles of the nostrils is double the distance from their centre to the point of the snout, or their nearest distance from the pectoral margin. The teeth are tricuspidate; their central cusps are erect and longer than the lateral horizontal ones. In both jaws the teeth are confined to the central third, on each side of which in the upper jaw appears a notch corresponding to a minute prominence in the lower jaw. The depressed tongue occupies the whole breadth of the mouth. The margin of the spiracles carries no denticle. The body is naked. The ventral fins are elongated tetragonal, with the posterior angles rounded. The male appendages project beyond the inner margins of the ventrals, and extend to the root of the caudal spine. The length of the tail varies: in the very young it is shorter than the body; later it becomes a little longer than the body. It is depressed towards the spine, from thence it is cylindrical, very slender and tapering. It has no fins. The slender spine is situated at the anterior fifth. In the young, with the disk upwards of one foot in breadth, it is hidden in the integuments, and scarcely $\frac{1}{12}$ of the length of the tail. In a male, $15\frac{4}{5}$ inch in breadth, the spine is nearly $\frac{1}{13}$ of the length of the tail. The largest individual observed was taken in 1840 near the Island of Lantao, in the mouth of the Canton River; the disk measured 4 feet in breadth, 3 feet in length, and the tail 1 foot. The tail was armed with two spines situated close to each other; each about one inch in length. Single young individuals occur at all seasons in the Straits of Malacca.

Genus HYPOLOPHUS, *Muller und Henle*, 1837. Form of the body like *Trygon*. Tail beneath with a fin, not extending to the apex. Upper fin, absent. Differs principally from *Trygon* by the peculiar form of the mouth and the teeth. The centre of the lower jaw is pointed and projecting, and has on each side a forwards directed cavity. The margin of the upper jaw is excavated in the centre to receive the point of the lower jaw, and is very convex on each side. Teeth like paving stones, hexagonal, broader than long; in the upper jaw the teeth of the centre are small, those of the sides large; in the lower jaw they are nearly of equal size: the external ones smaller.

(*Young.*) Above reddish brown; the scaly portion of the head, back and tail lead-coloured; tail behind the spine, and caudal fin blackish brown; beneath whitish. Iris golden; pupil transversely oval, black. Inhabits *Sea of Pinang*, *Malayan Peninsula*, *Singapore*, Bay of Bengal, Mouths of the Ganges, Red Sea, Indian Ocean, Java, Madura. The disk is rhombic, with rounded angles. In the very young the snout is more pointed than in the older. The external angles of the ventrals are acute, the internal obtuse. The distance between the nostrils is one half of their distance from the snout. The distance from the snout to the eyes exceeds by one third that between the eyes. The snout is above covered with distant tricuspidate scales. On the upper part of the head, back and on the root of the tail they are smooth, hexagonal, with their anterior and posterior margins denticulated and with a shallow cavity in their centre. Three large heart-shaped convex plates, placed longitudinally, appear on the scapular region. Of the three the central one is the largest, the anterior the smallest. The tail is from three to four times the length of the body. As far as the spine it is depressed, trigonal and tapering; the portion supporting the caudal is compressed and with minute lanceolate scales; the rest is very attenuated like a whip cord. The spine is situated a little behind the anterior third of the tail; its length varies from $\frac{1}{8}$ to $\frac{1}{3}$ of the tail. The caudal membrane commences beneath the root of the spine and continues beyond the

central third of the lower margin of the tail. Its height is less than that of the part of the tail to which it is attached. Single young individuals occur at all seasons in the Straits of Malacca.

Dimensions.

From the snout to the eyes,	2
Distance between the eyes,	$1\frac{3}{8}$
Breadth of the disk,	$7\frac{6}{8}$

Genus TAENIURA, *Muller und Henle*, 1837. Disk rounded. Tail not much longer than the body, depressed in front of the spine, compressed behind it, with a high inferior fin, which commences from the spine and extends to the apex of the tail. The upper margin of the tail carries frequently a low longer or shorter skinny hem, extending to the apex of the tail. The caudal spine a little in front of the middle of the tail. Nostrils approximated as in *Trygon*. Teeth flattened, with a transversal protuberance, or pointed. Mouth straight or undulating. Membranous valve behind the upper jaw straight; that behind the lower jaw without papillæ.

Taeniura halgani, Lesson in Duperrey: Voy, II. 100.
Taeniura lymna, Muller und Henle, 171. 197, Taf. (Mouth.)

(*Young.*) Above brownish bronze, with numerous oval and round ultramarine spots; from the scapular region on each side of the back a broad ultramarine band, continuing on the sides of the tail to the root of the spine; caudal fin pale brownish, the lower margin edged with black; beneath greenish white. Iris narrow golden round the pupil, the rest dark blue; pupil transversely oval, black. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, Indian Ocean, Red Sea, Timor, New Ireland.

Dimensions.

From the snout to the mouth,	$0\frac{6}{8}$ inch.
From the mouth to the anus,	$3\frac{2}{8}$
Length of the tail,	6
„ of the caudal spine,	1
Distance between the eyes,	$0\frac{4}{8}$
Breadth of the disk,	$4\frac{4}{8}$

This species is of rare occurrence in the Straits of Malacca.

Fam. MYLIOBATIDIDÆ.

Genus MYLIOBATIS (*Dumeril*, 1817) *Muller und Henle*, 1841. (Aetobatis, *Blainville*, 1828.) Snout pointed, composed by the united, anterior pectoral rays. Nasal valves united, with straight margin. Mouth transversal. Both jaws with straight margin. Teeth hexagonal, in the centre a series of broader teeth, backwards, increasing in breadth. On each side smaller, tetragonal plates resembling paving stones, fitting into the zig-zags of the central teeth. The teeth of the upper jaw longitudinally and transversely convex; those of the lower jaw flat, scarcely somewhat concave; teeth of neither jaw occupy the entire breadth.

(3919) *Myliobatis nieuhofii*, (Bloch-Schn.)

Syn. Aquilæ marinæ species, Willoughby, 6, Tab. X. Fig. 3 (App.)
Raja nieuhofii Bl. Schn. 364
Russell, VII. Mookarah Tenkee.

Myliobatis nieuhofii, Müller und Henle, 177.
Myliobatis nieuhofii, Richardson: Report, 1845, 197.
Pari klawar of the Malays.

(*Young.*) Above yellowish brown, with six or more narrow transversal bands of deep bluish purple; beneath whitish; tail blackish brown; posterior half with irregular white spots. Iris golden, pupil vertically elliptical. Teeth pale amber-coloured. Inhabits *Sea of Pinang*, Indian Ocean, Coromandel, Chinese and Australian Seas, Mediterranean. In the very young the apex of the snout is double the length of the nasal valve. The pectorals are sickle-shaped. The dorsal is triangular, commencing at the root of the tail, and not extending beyond the apex of the ventrals. The length of the body is contained $2\frac{1}{4}$ times in the greatest breadth of the disk. The body is naked, and the tail without spine. The tail exceeds four times the length of the body. A female, observed at Pinang in May 1845, was of the following dimensions.

From the snout to the mouth,	$0\frac{5}{8}$ inch.
„ mouth to the anus,	$2\frac{5}{8}$
Length of the tail,	$14\frac{4}{8}$
From the root of the tail to the dorsal,	$0\frac{2}{8}$
From the snout to the eyes,	$0\frac{3}{8}$
Distance between the eyes,	$0\frac{6}{8}$
Breadth of the nasal valve,	$0\frac{4}{8}$
Length of do.	$0\frac{2}{8}$
Greatest breadth, (between the external angles of the pectorals,)	$8\frac{8}{8}$

(3920) *Myliobatis milvus*, Valenciennes.

Syn. Myliobatis milvus, Muller und Henle, 178.
Pari klawar of the Malays.

(*Young.*) Above, pale fawn-coloured; on the head and back a number of distant anastomosing black lines, which on the anterior half of the root of the pectorals are arranged transversely, so as to make the ground-colour between them resemble very broad transverse bands; on the rest of the body, on the pectoral and ventral fins the black lines form an open net-work; the anterior margin of the pectorals, to near the apex, and the dorsal, pale fawn-coloured without black meshes. Anterior sixth of tail fawn-coloured, indistinctly ringed with blackish brown; rest of the tail black; abdomen white. Iris narrow golden round the pupil, the rest fawn-coloured; pupil heart-shaped, with the apex downwards. Teeth pale amber-coloured. Inhabits *Sea of Pinang*, Red Sea. The form of the body, teeth and fins is similar to that of *M. nieuhofii*, but the position of the dorsal fin differs. It commences farther behind the termination of the base of the ventrals, close to their apex, beyond which it does not extend. The male appendages are shorter than the corresponding margin of the ventrals; they are white, with a black longitudinal streak above. At its root the tail is greatly compressed, two edged, like the blade of an oar; the rest is slender like a whipcord; its length is $4\frac{1}{2}$ times that of the body. The tail has neither spine nor fin. The body is naked. A single young male was observed at Pinang in August 1846. It was of the following dimensions:

From the snout to the mouth, ...	$1\frac{2}{8}$ inch.
„ mouth to the anus, ...	$6\frac{3}{8}$
Length of the tail, ...	$46\frac{2}{8}$
„ from the root of the tail to the dorsal, ...	$1\frac{1}{8}$

Genus STOASODON, *Cantor.* [Στοὰ, arcade; ὀδὼν, tooth. Substituted for *Aëtobatis*, Muller und Henle, 1841, preoccupied by *Aëtobatis*, Blainville, 1828, which as observed, is a synonyme of *Myliobatis*. The characters given are those of M.M. Muller und Henle.] (*Equivalent to* Aëtobatis, *Muller und Henle*, 1841.) Snout acute, undivided. The lower margin of the united nasal valves deeply indented. The frænulum of the nasal valve is covered with papillæ which are transversely disposed in front of the upper jaw. On the dorsal surface of the nasal valve, near the external margin, a lobule with fringed edge. Lower jaw acute, projecting beyond the upper; upper jaw with a straight margin. The dental laminæ of both jaws form a series, without smaller lateral teeth; in the lower jaw the laminæ are arched and parallel to the margin of the jaw. The laminæ do not occupy the whole breadth of the jaw.

(3921) *Stoasodon narinari*, (Bloch-Schneider.)

Pari lung of the Malays.

Above greenish olive or greenish grey; a little behind the occiput and behind the anterior margin of the pectorals appear more or less numerous greenish-white rounded spots, edged with black; tail behind the spine black; abdominal surface of disk and tail as far as the spine greenish white; rest black. Iris greenish golden; pupil vertically elliptical. Teeth greenish white. Inhabits *Sea of Pinang, Malayan Peninsula, Singapore*, India Ocean, Red Sea, Bay of Bengal, Mouths of the Ganges Sumatra, Java, Madura, Brazil, Surinam. Greatest Breadth: 3 feet. The snout is conical and about $\frac{1}{4}$ broader than long, and not quite double the length of the nasal valve. The nasal lobule is broad conical. The shape of the disk resembles that of *Myliobatis milvus*. The dorsal fin commences near the termination of the base of the ventrals, but terminates at some distance in front of the apex of the ventrals. The latter are elongated, about thrice as long as broad. The male appendages do not extend beyond the corresponding margin of the fin, and are shorter in the young. The tail is trigonal as far as the spine, the rest is compressed and flagelliform. Its length is thrice or four times that of the body. The spine is situated immediately behind the termination of the dorsal; its length equals its distance from the anus. Some individuals are armed with a second somewhat longer spine, a little behind the root of the former. The dental laminæ of the upper jaw are very slightly arched; the anterior

margin of the external laminæ exhibits numerous vertical denticulations. The laminæ of the lower jaw are but $\frac{2}{3}$ of the breadth of those of the upper, but they are more convex, forming in the centre an obtuse angle. Single young individuals occur at all seasons in the Straits of Malacca. The following dimensions were taken from a young male, armed with two spines :

From the snout to the nostrils, ...	1 inch.
From the nostrils to the mouth, ...	$0\frac{4}{8}$
From the mouth to the anus, ...	$5\frac{6}{8}$
Length of the tail, ...	$33\frac{6}{8}$
Distance between the nostrils,... ...	$0\frac{5}{8}$
„ „ the eyes.	$1\frac{1}{8}$
Breadth of the mouth, ...	$0\frac{5}{8}$
Distance from the snout to the eyes,	$1\frac{1}{8}$
Length of the anterior spine, ...	$1\frac{2}{8}$
„ of the second do., ...	$1\frac{0}{8}$
Greatest breadth of the disk, ...	$11\frac{5}{8}$

Genus RHINOPTERA, (*Kuhl*) *Muller und Henle*, 1841. The snout deeply divided by a central incision. The cranial fins are not on a level with the pectorals, but lower down, and are fixed at the inferior margin of the root of the pectorals. The rays of the cranial fins commence farther back than the termination of the pectorals. The lower margin of the nasal valve is straight ; the external angle acute ; on each side of their dorsal surface a longitudinal fold. The teeth stand side by side in 3 to 5 rows of broad hexagonal plates which laterally decrease in size. Outside appear several rows of smaller teeth, which are not broader than long. They occupy the entire breadth of the jaw.

(3922) *Rhinoptera adspersa*, Valenciennes.

Syn. Rhinoptera adspersa, Muller und Henle, 183.
Pari daun of the Malays.

(*Young.*) Above pale fawn-coloured ; beneath white. (*Older.*) Above chocolate brown or greenish olive ; beneath white. Iris golden fawn-coloured ; pupil vertically elliptical. Teeth yellowish white. Inhabits *Sea of Pinang*, Indian Ocean. The teeth of both jaws are similar ; those of the centre row are hardly thrice as broad as long. The other rows gradually decrease towards the sides of the mouth. There are nine rows in the upper jaw, seven in the lower. The margin of the nasal valve is finely denticulated, its length is $3\frac{1}{2}$ times its height. The anterior margin of the pectorals is slightly convex ; the posterior concave ; the angles acute. The ventrals are tetragonal, considerably projecting beyond the pectorals. The dorsal commences at the termination of the ventrals, and extends a little beyond their apex. The tail is about 3 to $3\frac{1}{2}$ times the length of the body ; the anterior third is greatly compressed ; the rest flagelliform. At a short distance from the dorsal is situated a small spine, but little longer than the base of the dorsal ; a little behind it appears a second, scarcely longer than the preceding spine. In the young the back is smooth. In older individuals M.M. Muller und Henle describe the back as being rough from minute spines with stellate base. At Pinang this species occurs at irregular intervals, singly or a few together. The following dimensions were taken from a young female.

From the incision of the snout to the centre between the nostrils,.....	1 inch.
„ the nostrils to the mouth, ...	$0\frac{2}{8}$
„ the mouth to the anus, ...	$5\frac{4}{8}$
Length of the tail, ...	24
Breadth of the margin of the nasal valve,.....	$1\frac{4}{8}$
„ of the mouth,.....	$1\frac{1}{8}$
„ of the disk, ...	13
Length of the posterior margin of the pectorals, ...	$0\frac{7}{8}$
„ of external margin of the ventrals.....	$1\frac{2}{8}$
„ of each caudal spine, ...	$0\frac{4}{8}$

Fam. DICEROBATIDIDÆ.

Genus DICEROBATIS, (Diarobatus, *Bloch,*) *Blainville*, 1828. (Cephalopterus, [*Dumeril,*] *Risso*, 1810.[Pre-occupieb dy *Cephalopterus*, Geoffroy, 1809, (*Aves*).]—Cephaloptera, *Risso*, 1826). Mouth on the abdominal surface. Teeth of both jaws minute, flattened, like paving stones, of different forms. The rays of the pectorals extend closely to the skull. The anterior margin of the pectorals is convex from the skull behind the eyes to the apex. [*Cephaloptera*, Muller und Henle, page 184.]

(3923) *Dicerobatis eregoodoo*, (Cuvier).

Syn. Russell : page 5, No. IX. Eregoodoo Tenkee. R. (Dorsal view).
Cephaloptera eregoodoo-tenkee, Cuv. R. A. II. 402 (1).

(*Young* ?) Above intense purple, with blue and violet reflections ; at the apex of the dorsal fin a whitish rounded spot ; external margin of ventrals white ; upper (external) surface of the cranial fins, and side of the head behind the eyes white ; lower (internal) surface of the cranial fins silvery grey, of a chequered appearance, produced by the transverse divisions of the rays ; the apex and internal margin broadly brimmed with black ; beneath white ; tail, as far as the ventrals extend, white, rest black ; margin of the snout and both jaws black. Iris purple ; pupil vertical, resembling the figure 8, or two vertically placed balls. Inhabits *Sea of Pinang*, Coromandel. The inner half of the anterior margin of the pectorals is very slightly concave, the outer half convex ; the posterior margin is concave : the external and internal angles acute. The length of the pectorals, from their origin, above and a little behind the eye, to their internal angle, is about $\frac{2}{3}$ of the greatest breadth of the disk. The ventrals project but little beyond the

pectorals. The male appendages are about $\frac{1}{3}$ of the internal margin of the ventrals, slender and throughout attached to the margin. The tail slightly exceeds $1\frac{1}{2}$ times the length of the body; it is very slender, flagelliform, and nearly throughout tetragonal. The dorsal fin has the appearance of being triangular, but it has a posterior very short margin. It commences a little in front of the ventrals and terminates a little behind their termination. The apex of the dorsal hardly extends beyond the anterior half of the ventrals. The body is smooth to the touch. The upper surface of the head and the throat are perforated by numerous pores. At the posterior part of the back appear some very minute scales or spines, which resemble white dots. They are distant and offer no resistance to the touch. The tail is naked and without spine. The anterior margin of the head (the snout), between the cranial fins, is concave. The distance from the centre of this margin to the mouth is $\frac{1}{3}$ of the breadth of the mouth. The length of the cranial fins, from their origin a little behind the mouth to their apex, equals the distance between both fins across the throat. Both are parallel, not diverging, as they appear in M. M, Muller and Henle's figure of *Cephaloptera kuhlii*. They are turned upwards, their upper surface being longitudinally hollowed. The spiracles are very small, hid beneath the origin of the pectorals. The margin of the nasal valve is straight and covers nearly the whole of the upper jaw. The angles form a conical lobule. The narrow band of teeth extends in both jaws not quite to the angle, occupying the central $\frac{5}{7}$ of the breadth of the mouth. The teeth are uniformly minute, flattened, of a pentagonal shape, with backwards directed points. They have frequently two or three such points. They are generally twice broader than long, but in both jaws appear here and there a single tooth broader than the rest, as if composed of two or three teeth soldered together. The upper jaw has 80, the lower 95 rows of teeth, each consisting of 6, rarely 7. Behind the upper jaw appears a large membranous valve, the free margin of which is convex. There is no trace of a tongue. The equidistant gill-openings are arranged on two backwards converging lines. Each opening is of this figure ∽, the first being double the length of the fifth. The only individual examined, was observed at Pinang in February 1845. It was a male, apparently young, of the following dimensions:

From the centre between the cranial fins to the centre of the snout,	$3\frac{2}{8}$ inch.
From the centre of the snout to the mouth,	$1\frac{2}{8}$
„ the mouth to the anus,	11
Length of the tail,	$19\frac{2}{8}$
Distance between the nostrils,	$2\frac{7}{8}$
„ from the nostrils to the mouth,	$0\frac{5}{8}$
Breadth of the mouth,	$3\frac{5}{8}$
Length of the cranial fins,	$5\frac{1}{8}$ inch.
Distance between them,	$5\frac{1}{8}$
„ between the eyes,	5
Base (Length) of the pectorals,	$13\frac{3}{8}$
Breadth of do.,	$13\frac{1}{8}$
Base of the dorsal,	$1\frac{5}{8}$
Anterior margin of do.,	$2\frac{1}{8}$
Posterior „ of do.,	$0\frac{3}{8}$
Superior „ of do.,	$0\frac{7}{8}$
Length of the ventrals,	$2\frac{3}{8}$
„ „ „ first gill-opening,	$1\frac{4}{8}$
„ „ „ fifth do.,	$0\frac{7}{8}$
Distance between the first gill-openings	$3\frac{3}{8}$
Greatest breadth of the disk,	$30\frac{5}{8}$

The stomach is elongated cylindrical, half the length of the body; the intestines equal the length of the body. This fish agrees in several characters with Russell's *Eregoodoo Tenkee*, No. IX. R, (*not* No. IX. N, from St. Helena.) M. M. Muller and Henle express some doubt as to the identity of Russell's No. IX. and *Cephaloptera olfersii*, Muller, (*Plagiostomen*, page 185) from Brazil. According to the description of M. M. Muller and Henle, the latter differs from the present species in the following characters. In *C. olfersii* the distance of the mouth from the head is in proportion to the breadth of the mouth as 8 to 13: in the present species that distance is $\frac{1}{3}$ of the breadth of the mouth, or as 1 to 3. In *C. olfersii* the length of the cranial fins compared with their distance is as 8 to 11; in the present species both are equal. In *C. olfersii* the length of the pectorals, measured from their origin on the skull, equals half the breadth of the disk; in the present species their length is less than the breadth of the disk.—*No.* 208 *to* 210 *of Bengal As. Soc. Jour. October to December* 1849.

Works on Indian fishes. As some readers may be interested in the subject of Indian Ichthyology it may prove of use to enumerate the works in which Fishes of the Indian Seas and rivers are treated of. Most of those have been referred to in the foregoing pages, as Dr. Russell on the Fishes of the Coromandel Coast, 2 vols. folio, with plates; Dr. Hamilton Buchanan, "An Account of the Fishes found in the River Ganges and its Branches," 4to, with a volume of plates. Several of Dr. Buchanan's Fishes are figured in the late Gen. Hardwicke's Zoological Illustrations, according to Mr. McClelland. As. Res. XIX. p. 221; Bennett, on the Fishes of Ceylon; Mr. McClelland, on the Indian Cyprinidæ, As. Res. XIX. p. 217, Cantor on some Fishes of the Bay of Bengal, Journ. Royal Asiatic Society; Col. Sykes, on the Fishes of the Deckan, Transactions of the Zoological Society, Fische aus Caschemir, by M.M. Von. Hugel and Heckel; while many of the Indian Fishes, which are known to the French, are described in the Historie des Poisons of M.M. Cuvier and Valenciennes.

(3924) FISH, ARTIFICIAL HATCHING OF, In China, the hatching of eggs by artificial heat is well known, and extensively practised, as is, also, the hatching of fish. The sale of spawn for this purpose forms an important branch of trade in China. The fisherman collects with care on the margin and surface of water, all the gelatinous matters that contain spawn of fish, which is then placed in an egg shell, which has been fresh emptied, through a small hole, which is then stopped, and the shell is then placed under a setting fowl. In a few days, the Chinese break the shell in warm water (warmed by the sun); the young fish are then kept in water until they are large enough to be placed in a pond. This plan, in some measure, counteracts the great destruction of spawn by troll-nets, which have caused the extinction of many fisheries.—*Bonynge America, page* 165. See also FISHERIES.

(3925) FISH HOOKS.

Hamecons, FR. | Fischangeln. GER.

Are well-known instruments made of the best smooth, round, steel wire. In the United Kingdom they are manufactured chiefly at Redditch, in Worcestershire.—*Faulkner.*

(3926) FISH LIVER OIL. Is prepared chiefly on the Western Coast of India, although some is now made at Madras. The liver of the white shark is that generally used. The mode of preparing the best Cod liver oil, which is equally applicable to "Fish liver" is thus described.

"*Cod Liver Oil.*"—The proper season for preparing this oil is early in January when the livers are plump, firm, large, white, and full of oil—the livers are sometimes found diseased, and are specifically lighter than water, these should be rejected. Good livers should cut smooth, and not tear, when cut none of the substance should flow out in a half liquid state. The quantity of oil produced by livers depends much upon the time of the year. In the beginning of January 1000 livers were found by experiment to yield 37 Imperial gallons, and at the end of February an equal number only gave 23 gallons of oil. In the beginning of January 1000 livers of average size weighed 900 lbs. whilst in the last day of March the same number weighed only 575 lbs. The oil at these different seasons was equally pale, and the livers equally white, although much smaller and more flabby in the latter season. To prepare the oil—Wash the livers very carefully, first removing the gall bladders which adhere to them, and infuse them in rain or other water free from salt. Place them over the fire and never allow the heat to exceed 120 or 130°. On this head especial care must be taken, a higher degree of heat although yielding a larger product, communicates a rank fishy taste and smell and heightens the color of the oil, thereby rendering it disgusting to the Patient.—*M. E. of* 1855.

Medicinal—Seer Liver—Shark Liver and other Fish oils (used in cases of Rheumatism, Atrophy, Phthisis, Glandular swellings and all diseases of a strumous nature) were exhibited, of fine quality, from Mangalore, Tellicherry, Masulipatam and Pondicherry. The Oil is obtained from different fishes. Drawings of these would be interesting. There is an active demand for this article at all the Sea ports of the Western Coast, and the product has become of great importance as the Export Return shows. The preparations of fish oil is chiefly confined to Malabar and the Western Coast, whence it is exported to England in large quantities, the demand is also yearly increasing.

(3927) FISHMAWS.

Poota (large), Sozeelee (small), GUZ. HIND.

A term applied in oriental commerce to the air-bladder, sounds, or swims of certain large fishes, found in the Indian ocean. It is an article of luxury with the Chinese; and forms an important article of export from all the coasts. Small quantities of the superior kind are occasionally sent to England, from which it is supposed Isinglass is made. There are two kinds of fishmaws, distinguished by the terms *Poota* and *Sozeelee*, the difference consisting merely in the size—the latter being about one-fourth the size of the former. See AIR-BLADDER: ISINGLASS.

(3928) FISHING-NET FLOATS. Several light porous woods, such as *Gyrocarpus Jacquini* and *Salmalia Malabarica*; and the fruit of the Baobab are used as floats for fishing nets.

(3929) FISH ROW.

(3930) FISH SALTED. SALSAMENTA.

Curruadoo, TAM. | Kharie mutchie, DUK.
Ains. Mat. Med p. 154.

(3931) FLACOURTIA, the type of the order *Flacourtiaceæ*, was named in honour of Etienne de Flacourt, a director of the French East India Company, and the commander of an expedition to Madagascar in 1648, of which he gave an account. This genus is dicœcious; the staminiferous flowers have their stamens densely crowded, a hemispherical receptacle, and are glandless at the base; the pistilliferous flowers have the calyx 4-5-cleft, deciduous; the stigmas 4-9, each furnished with a longitudinal furrow above; the seeds long. The species are thorny shrubs, with whitish sepals and yellow stamens.

(3932) FLACOURTIA CATAPHRACTA. MANY-SPINED FLACOURTIA.

Panijala. HIND. | Panayala, DUK. BENG.
Taliputrie, BEN. | Talisha, SANS.
Gen. Med. Top. p. 211.

A fruit tree in gardens at Kotah. The *Flacourtia cataphracta* affords a popular medicine in Behar. The small leaves and shoots resemble

rhubarb in flavour, and are used as a gentle astringent in the dose of half a drachm in powder. An infusion of the bark in cold water is also employed as a remedy in hoarseness.—*O'Shaugh. page* 207. The young shoots and leaves of *F. cataphracta*, which have the taste but not the bitterness of rhubarb, are considered astringent and stomachic, and are prescribed in the Circars accordingly.—*Eng. Cyc.*

(3933) FLACOURTIA INERMIS has elliptical crenato-serrated leaves, with short axillary racemes of hermaphrodite flowers. It is an unarmed tree, attaining a height of 30 feet. It has reddish-purple berries of a pleasant acid taste. It is a native of the Moluccas, where it is also extensively cultivated for the sake of its fruit. There are several other species of *Flacourtia*, all of them yielding edible fruits.

(3934) FLACOURTIA RAMONTCHI has roundish ovate acute crenated leaves. This shrub attains a height of 8 feet, and is a native of the island of Madagascar, where it is called Ramontchi. The fruit, which is edible, is about the size of a small plumb, is red when ripe, at length becoming violet-coloured. It has a sweet and acid taste. There is a small island off the coast of Madagascar which is covered with these trees. This island is called by English sailors Plum-Tree Island: by the French, Isle aux Prunes.

(3935) FLACOURTIA SAPIDA, Roxb. FLACOURTIACEÆ. The Paneola Plum.

Pedda Canrew pundoo, TEL. | Bincha, DUK.

Pedda Canrew is the Telingoo name of a pleasant tasted fruit, the produce of a small sized tree a native of the mountainous parts of the Coromandel coast.—*Ainslie, p.* 230. *Flacourtia sapida* has elliptical leaves, serrated, bluntish at both extremities. It is a native of the mountainous districts of the East Indies. The fruit is about the size of a common currant, and of a red colour. The fruit is eaten by the natives, and the tree is called by the Telingese Pedda Canrew.—This fruit tree is generally cultivated about Calcutta, and grows to the size of a common plum: it resembles a gooseberry in appearance, the skin thin and shining and of a purple appearance. The tree is not common on the Western side of India, and only one or two are to be found in Bombay. The fruit there is not so large as in Calcutta, where it is common during the rains; it contains from ten to twelve seeds, and is both palatable and wholesome, and well worthy of more general cultivation. The tree grows to a large size.

(3936) FLACOURTIA SEPIARIA, Roxb.

Canrew pundoo, TEL. | Samla, SANS.

Canrew pundoo is the Telingoo name of a not unpleasant tasted, small fruit, which grows on a thorny, shrubby plant, found in the most uncultivated parts of the Coromandel coast. The Tamool appellation of this fruit is Sottay ela pullum, in Dukhanie it is called Jootay karoonday.—*Ainslie, p.* 222. The infusion of *F. sepiaria* is thought to be useful as a remedy for the bites of snakes.—*Eng. Cyc.*

(3937) FLACOURTIACEÆ OR FLACOURTIANEÆ, *Bixads*, a natural order of Plants belonging to Lindley's parietose group of Polypetalous Exogens. It has from 4-7 definite sepals cohering slightly at the base; the petals equal in number with the sepals, and alternate with them, sometimes wanting; the stamens hypogynous, equalling the petals, or twice as many or some multiple of them, and sometimes appearing as scales forming a nectary; the ovary roundish, distinct, sessile, or slightly stalked; the style absent or filiform; the stigmas equal in number to the valves of the ovary, more or less distinct from each other; the fruit 1-celled, sometimes indehiscent and fleshy, sometimes capsular, 4-5-valved, filled with a fine pulp inside; the seeds few, thick, usually enveloped in a pellicle formed by the withered pulp, the albumen fleshy, somewhat oily, the embryo straight in the axis, with the radicle turned to the hilum, and therefore usually superior; the cotyledons flat, foliaceous. This order consists of shrubs and small trees, with alternate simple coriaceous leaves on short stalks, and axillary many-flowered peduncles. The affinities of this order are with *Samydaceæ*, *Lacistemaceæ*, *Pangiaceæ*, and *Tiliaceæ*. They may be distinguished from all other plants by their unilocular fruit having their inside wholly covered with the placentæ. About 31 genera and 85 species are referred to this order. These plants are natives of the hottest parts of the East and West Indies and Africa. Three of the genera—*Flacourtia*, *Hydnocarpus*, and *Chaulmoogra*—yield plants used by man; few, if any, are cultivated for ornament. *Hydnocorpus* (from ὕδνον, a tuber, and καρπος, a fruit) has diœcious flowers, the staminiferous ones with 5 stamens, 5 sepals, the two outer ones being ovate, 5 petals with villous margins furnished with a scale on the inside; the berry is spherical, terminated by four reflexed tubercles. There is only one species of this genus, which is a tree about 30 feet in height, the *H. venenata* of Gærtner, and *H. inebrians* of Vahl. It is a native of Ceylon and of the Canarese forests. The fruit when eaten produces sickness, giddiness, and a dangerous form of intoxication. It is greedily devoured by fishes, which become stupified, but when taken in this way they produce poisonous effects as food. *Chaulmoogra* (*Gynocardia*) is a diœcious genus; the staminiferous flowers with a 4-5-lobed calyx, 5 petals with a scale at the base of each; the pistilliferous the same, except the stamens, the ovary superior, 1-celled, with numerous ovules, and 5 parietal placentæ, 5 styles; the fruit succulent, dry, 1-celled, many-seeded. *C. odo-*

rata has short-stalked, alternate, bifarious, drooping, lanceolate, entire, acuminate, smooth, exstipulate leaves, ·6 to 10 inches long, 1½ to 2½ inches broad. It is a native of Silhet. The seeds are employed extensively by the natives of India as a remedy for cutaneous diseases. In those cases they are applied externally; the testa being removed from the seed, the perisperm is beaten up with clarified butter into a soft mass, and applied to the part affected three times a day. The Indian names of this plant are Chaulmoogra and Petarkura. [PANGIACEÆ.] Other genera belonging to this order are—*Ryanæa*, named by Vahl after John Ryan, who collected plants in Guyana; *Patrisia*, named after M. Patris, who collected plants in Guyana; *Roumea*, after Phillippe Rose Roume de St. Laurent, an agent of the French government at St. Domingo, who was of great service to Poiteau, who travelled there; *Kiggelaria*, after Francis Kiggelar, a Dutch botanist of the 17th century; *Stigmarota*, *Melicytus*, *Erythrospermum Pangium*, and *Vareca*. (Don, *Dichlamydeous Plants*; Lindley, *Natural System*; Lindley, *Flora Medica*; Burnett, *Outlines of Botany*)

(3938) FLAGELLARIA INDICA, A species of flagellaria is often seen, in Tenasserim and is easily recognized by the tendril it puts forth at the end of its leaves.—*Mason.*

(3939) FLANNEL.

Flannelle, FR.; Flanell, GER.; Looee HIND.

A well-known, slight, loose, wollen, stuff, of various degrees of fineness.—*Faulkner.*

(3940) FLAX, LINSEED, *Linum usitatissium*, *Linaceæ*).

Atasee, SANS.	Mushina, BENG.
Atees, Ulsee, HIND.	Kutan, PERSIAN.

The flax plant is one of those which was cultivated by the earliest of the civilised nations of antiquity, which has continued to be so to the present time, and is becoming every day of still greater importance. We may see from the paintings in the tombs of Egypt, that it was early cultivated in that country; and we can also prove that it was so, from a microscopic examination of mummy-cloth. We read in the book of 'Exodus'[1] [[1] The word Pishtah undoubtedly refers to the Flax plant, of which the preparation for its fibre is so clearly represented in the Grotto of El Kab. The words *bath*, *butz*, and *sheesh*, which occur so frequently in the Scriptures, are supposed to indicate different kinds of Linen. But it has been doubted whether, in a language like the Hebrew, it is probable that so many names are applied to the produce of one plant, or whether it is not more probable that they refer to the products of different plants. Dr. Royle has ventured to think that Linen, Cotton, and Hemp were all known; and are mentioned—Cotton (karpas), in Esther i, 6. *Bad* is very similar to the Sanscrit *pat*. *Shesh* differs only in the aspirate from *husheesh*, which is one of the Arabic names of the Hemp; as Dr. Royle has pointed out in the respective articles in Kitto's Cyclopædia of Bibical Literature.] of the flax and the barley being smitten by the plague of hail in Egypt, and in 'Joshua' of the spies, who had been sent to report on the state of Jericho, being hid with stalks of flax. From many other passages, we know that the spinning and weaving of Flax were common occupations of the people in Palestine. Subsequently, it was much cultivated both by Greeks and Romans. In India, Flax has also been cultivated from very early times, but strange to say, for its seed only, and not on account of the fibre; which everywhere else is the principal object of attention. This is probably owing to India possessing, as one of its indigenous products, the Cotton plant, which requires only the bursting of its fruit to display an elegant and easily spun material, which can be obtained from the Flax only after considerable labour. We have lately seen how important the Cocoa-nut Palm, one of the princes of the vegetable kingdom, is, not only to the countries where it is produced, but also to those into which its products are introduced. The Flax plant, on the contrary, is one of the humblest of those which are cultivated, and yet it is hardly less important, though not particularly useful as an article of diet. Its slender stem, narrow leaves, and beautiful blue flowers, give it an elegant appearance. Its smooth and shining seeds have their external coating formed of much condensed mucilage, while the white kernel is gorged with oil, especially valued for its drying properties; and the refuse or oil-cake affords a nutritious diet for cattle. The fibre or Flax separated from the stem may be made use of for cordage, for coarse fabrics, or for the finest cambrics and lawns. Hence it is a principal object of attention in Russia and Poland, a highly successful culture in Belgium, carried on also in Germany, France, and Italy, the object of frequent legislative enactment in England, and of recent most successful cultivation in Ireland. Hence, also, it was re-established by the late Pasha Mahomed Ali in Egypt. It has been frequently recommended for culture in India on account of its fibre, as it already is in almost every part of that country for its seed. Upon consideration, it will no doubt appear remarkable that this small annual plant should be profitably cultivated over so great an extent of the globe, and in apparently so great a diversity of climate. But the fact is that the winters of these southern latitudes enjoy a temperature which nearly approaches that of the summers of more northern countries. Therefore, in Egypt and India, Linseed is sown in autumn, and the stalks harvested in early spring, even before the seeds have begun to be sown in the more northern places where it is cultivated. This winter culti-

vation of southern latitudes has probably given origin to the autumnal sowings of European latitudes. But this lowering of temperature is not all that the plant requires for the production of fine flax, as we shall immediately more particularly inquire. But the natives of India, who are more ingenious in their devices and more successful in their agriculture than is generally allowed, have adopted methods of culture, such as thin sowing, though intermixed with, or in drills as an edging to, other crops, which ensures them an abundant crop of the produce they desire—that is, the seed—which is large and plump; while the stems remain short, branch much, flower freely, and become loaded with bolls filled with the seeds, which abound both in mucilage and in oil. Notwithstanding the endeavours of successive English governments, the supply of home-grown Flax has never reached the extent required by their manufacturers. At present, it is considered the consumption is equal to 150,000 tons. About 70,000 tons were, for several years, annually imported: or more precisely, in the year 1831 46,820 tons: in the year 1843, about 72,000 tons were imported; but in 1853 no less than 94,000 tons, or an increase of about 31 per cent. in the last decennial period. If the 150,000 tons be valued at an average of forty, or, according to others, at fifty pounds a ton, the amount is enormous. To this must be added "£1,500,000, the value of 650,000 quarters of linseed, used as seed and for crushing purposes; and about £500,000, the cost of 70,000 tons of oil-cake, which England annually imports, in addition to that made at home, for feeding purposes. The quantity of Flax fibre necessary to supply the demand of the United Kingdom would consume the produce of 500,000 acres; while in Ireland, during the year 1852, only 136,000 were cultivated, and probably, not a fourth of that quantity in the rest of the kingdom." (Wilson.) The seed is imported from India, Egypt, Russia, Sicily, Prussia, and Holland; and the oil-cake from France, Germany, and the United States. Mr. Nichols says—"The quantity of Flax which ought to be cultivated in any locality, must, in some measure, be governed by the quantity of labour there obtainable. One acre in a hundred, and one in fifty, have each been named as a suitable proportion to be applied for the growth of Flax. In former times the farmer was by law required to cultivate one acre with Flax, out of every sixty acres occupied." And he further observes: "If the quantity of Flax grown be limited by the labour which can be obtained, so may the amount of obtainable labour be said to indicate the extent to which culture ought to be carried in any locality. It is calculated that an acre of good Flax, as it stands in the field, containing, say about fifty stone of fibre, will afford employment for from twelve to fourteen weeks to a man skilled in the several processes of its preparation." But it is not to men only that the Flax affords employment, but also to women and to children; as it is skill rather than strength that is required for many of the operations. Hence, its introduction is very desirable in suitable localities, where population is abundant. Success in culture will, therefore, depend on many considerations; as it is necessary to have a suitable soil and favorable climate; also, a sufficient population, with facilities for the sale and the transit of the produce. At present, Flax is produced over a very wide area, and there seems no sufficient reason why this may not be still further extended.

The flax plant and its products.—The Flax plant belongs to the natural family of Linaceæ, so named from the botanical name (Linum) of the genus to which it belongs. The species are found chiefly in temperate parts of the world, with a few in tropical regions; most are remarkable for the tenacity of the fibre of their inner bark. The native country of the Flax plant is unknown; but as it was cultivated by the earliest civilised nations, it is probably a native of oriental regions, from which it has travelled southwards into India and northwards into Europe.

Description of plant.—It is an annual, with long and slender but fibrous roots, which penetrate to a considerable distance into the soil, where this is loose and friable. The stem is smooth, simple, and erect; branched, or, as usually cultivated, branching only towards the top; from one and a half to three feet in height. It consists of a pith and woody part, with the layer of bast fibres covered with cuticle on the outside. The leaves are alternate, sessile, linear lanceolate, and smooth. The flowers, of a blue colour, are arranged in a corymbose panicle. The sepals or green outer leaflets of the flower are five in number, ovate, acute, slightly ciliated, nearly equal to the capsule in length. The petals, blue in colour and five in number, are obscurely crenate, comparatively large, and deciduous. The stamens are equal in number to the petals and alternate with them, having their filaments united together near their bases into a kind of ring. The ovary, or young seed-vessel, is divided into five cells, and is surmounted by five stigmata. Capsule, or *boll*, roundish, but rather pointed at the apex, divided into five perfect cells, each of which is again subdivided by an imperfect partition, thus forming ten divisions, each of them containing a single seed. These seeds are oval in shape, flattened or plump, smooth and shining, of a brownish colour externally, but sometimes white; always white internally: the seed-coat mucilaginous, and the kernel of the seed oily and farinaceous. Besides other species of the same genus, such as *L. perenne*, which affords a strong though coarse

fibre, and one difficult to separate from the woody matter, there are some varieties of the true Flax plant known; but these are much fewer than is the case with most other long-cultivated plants. Dr. Lindley, as already quoted by Mr. J. Wilson, in his paper on 'Flax; its Treatment Agricultural and Technical' (in 'Journ. Royal Agric. Soc.,' vol. xiv, p. 188, 1853), describes two different forms: 1. The *Linum humile* or *crepitans* (the Springlein or Klanglein of the Germans), a plant somewhat shorter and more inclined to branch than the other, and possessing larger capsules, twice as long as the calyx, which burst with considerable elasticity when ripe; its seeds, too, are both larger and of a paler colour. 2. The *Linum usitatissimum* or true winter flax (Winterlein of the Germans), which has smaller capsules, scarcely larger than the calyx, not bursting with elasticity, but firmly retaining their seeds, which are of a dark brown colour. The Indian plant, called *ulsee* or *tesee*, may be considered a variety which has acquired certain characters from the peculiarities of soil, of climate, and of long and peculiar culture. It is always short, probably not more than eighteen inches in height, much branched, loaded with bolls, which are filled with large, ovoid, plump seed. That this retains its character even in other situations, appears from a fact, of which Dr. Royle has been informed by Mr. M'Adam, the able secretary of the Society for the Promotion of the Growth of Flax in Ireland. The Society having imported some seed for experiment from India, found that the plant did not grow beyond fourteen or eighteen inches. But that it is also ready to change its habit, is evident from facts to be detailed respecting the experiments which have been made in India. He has also been informed that in a recent experiment made by Mr. Burn, in Sindh, with thick sowing and irrigation, it grew at once to upwards of two feet. He has no doubt that, with a repetition of the process of thick sowing for a few times, the Indian seed would produce plants with tall, straight, and little-branched stems, each with but comparatively few bolls and seeds. A perfectly white variety of Linseed is common in the Saugur and Nerbuddah territories, which was brought to the notice of the Agricultural Society of India by Col. Ousley. Seeds sent by him were distributed to different parts of the country by the Society. Mr. Finch, of Tirhoot, after two years, returned five maunds; and stated that three fourths of his crop were destroyed by caterpillars, while the common Linseed grown in the vicinity of the white, was left untouched by them. The useful products of the Flax plant consist of the seeds and of the fibre or Flax. Linseed, or the seeds of the Flax plant, are oval, pointed in shape, compressed with a sharp margin; brownish coloured, smooth, and shining on the outside, but white internally, and without odour. The outside has a bland, mucilaginous taste, in consequence of the skin of the seed being covered with condensed mucus. The white part, or almond of the seed, has an oily taste, from containing fixed oil, which is separated by expression. These seeds, analysed by Meyer, consist, in one hundred parts, of 15·12 mucilage (nitrogenous mucilage with acetic acid and salts, according to some), chiefly in the seed-coat, 11·26 fatty oil in the nucleus. In the *husk*, emulsin 44·88, besides the wax 0·14, acrid soft resin 2·48, starch with salts 1·48. In the *nucleus*, besides the oil, gum 6·15, albumen 2·78, gluten 2·93, also resinous colouring matter 0·55, yellow extractive with tannin and salts (nitre and the chlorides of postassium and calcium) 1·91, sweet extractive with malic acid and some salts 10·88. The condensed mucus which abounds in the testa of the seed is readily acted on by hot water, and a viscid mucilaginous fluid is formed, in which are two distinct substances; one completely soluble in water, analogous to common gum called Arabine by chemists; the other portion is merely suspended, and is considered to be analogous to the Bassorine, found chiefly in Gum Bussora, and in Cherry-tree Gum. Alcohol produces a white flaky, and acetate of lead, a dense precipitate in mucilage of Linseed. Linseed oil, which we have seen is contained in the kernel of the seeds, is obtained by expression, and may be either cold-drawn, or, as usually obtained, after the seeds have been subjected to a heat of 200°. The former, as in the case of cold-drawn castor oil, is paler, with less colour and taste than Linseed oil prepared with the aid of heat. This of a deep yellow or brownish colour, of a disagreeable smell and taste, specific gravity 0-932, soluble in alcohol and ether; differing from many other fatty oils, especially in its property of drying into a hard, transparent varnish—a peculiarity which is increased by boiling the oil, either alone, or with some of the preparations of lead. "The yield of oil from a bushel of East Indian seed is 14¾ lb. to 16 lb.; of Egyptian, 15 lb; of Sicilian, 14½ lb. to 15½ lb.; of Russian, 11 lb. to 13 lb.; of English or Irish, 10¾ lb. to 12 lb." Linseed oil, according to Sace, is composed of Margarine and Oleine in nearly equal proportions. But the oleic acid of Linseed differs from that of other fatty bodies. The anhydrous acid is composed of carbon 46, hydrogen 38, oxygen 5. The Margaric acid is as usual composed of carbon 34, hydrogen 33, oxygen 3. The Glycerine obtainable from Linseed oil in large quantities, is also similar to that procured from other fats. Linseed, after having had the oil expressed from them, are in the form of a flat mass, commonly called *oil-cake*. This being reduced to coarse powder, forms the Linseed meal which is so commonly employed for making poultices, though these are also formed of the simply

powdered seeds. Here it is evident, from the internal oleaginous and external mucilaginous parts being all ground together, and their properties elicited by hot water, an admirable mixture is produced for making a readily made emollient poultice. From the chemical composition, it is also evident how nourishing the Linseed is likely to be, and, indeed, from experience, is well known to be, for fattening cattle.

Report on the culture of flax in India. "India having at least, for centuries grown the Flax plant, on account of the oil yielded by its seeds (Linseed), the country was naturally been looked to as a source of Flax fibre; the supply of which was so greatly diminished by the war with Russia. [The following formed the substance of a Report prepared by Dr. Royle in August, 1854, and is printed nearly as it was written.] The Belfast Chamber observe, that "as India annually exports nearly 100,000 quarters of seed to Great Britain and Ireland, it has been calculated that the plants which produced this quantity of seed would yield, annually, at least 12,000 tons of fibre—value, say £500,000; all of which now goes to waste." Besides the above quantity of seed, much is also exported to North America and to other countries, and much is consumed in the country in the form of oil, while the cake is in some places employed in feeding their cattle. There can be no doubt, therefore, that the question is one of considerable importance, not only to England which requires such immense quantities of Flax fibre, but to India, which produces such enormous heaps of seeds, and is supposed to waste so much of valuable exportable material. But it does not follow that the production of fibre, is in proportion to that of seed. Indeed, we have often to check vegetation, in order to favour the production of flowers and fruit; while an undue growth of the parts of vegetation, that is, of the stem, branches, and leaves, is often obtained at the expense of the parts of fructification. The subject, however, has not escaped notice. The earliest attempt to produce Flax in India seems to have been made by Dr Roxburgh about the beginning of this century, as at that time, the East India Company having established a Hemp farm in the neighbourhood of Calcutta, he made many experiments on the substitutes for Hemp and Flax. He also cultivated Hemp and Flax in the Company's farm at Reshera, in the neighbourhood of Calcutta. Of Flax, he says, it is very generally cultivated during the cold season in the interior parts of Bengal and Behar. "Samples of the Flax have frequently been procured by the Board of Trade, and sent to England to the Honorable Court of Directors, so that it is from home we may expect to learn its properties. If the Flax has been found good, large quantities may be reared at a small expense, as the seed alone which the crop yields must be more than equal to the charges to render it profitable to the farmer." ('Obs. on Subs. for Hemp and Flax,' p. 17.) Dr. Royle, as long since as the year 1834, stated in his 'Illustrations of Himalayan Botany:' "In India the Flax is cultivated only on account of its seed, of which the mucilage is valued as a demulcent in medicine, and the oil in the arts; but the plant, which in other countries is most valued, is there thrown away; and others, such as *Hibiscus cannabinus* and *Crotolaria juncea*, are cultivated almost in the same field, for the very products which this would yield. It seems, therefore, worthy of experiment whether a valuable product might not be added to the agriculturist's profits, without much additional expense." And again, in the year 1840, the Author called attention to this subject, in his 'Essay on the Productive Resources of India' In the year 1839, moreover, a Company was established, by the influence of Mr. A. Rogers, at one time one of the Sheriffs of London, expressly for the growth of Flax in India. Money was subscribed; a Belgian cultivator and a Belgian preparer of Flax were sent out to Bengal, with both Riga and Dutch seed, and all the tools which are employed in the culture and preparation of Flax in Europe. A pamphlet, moreover, was published, in which full directions were given for the culture and preparation of Flax, and illustrated with figures of the various tools employed for this purpose. The subject was warmly taken up by the Agricultural Society of India, and a small committee appointed of members who took a special interest in the subject. The directions of the Irish Flax Society were printed in their 'Proceedings,' as well as those of Mr. Andrews from the 'Northern Whig.' Translations of plain directions were made into the vernacular languages, which, as well as models of the tools, were distributed. The Gold Medal of the Society was offered for the production of a large quantity of Flax, and smaller prizes for the natives. Experiments were made by several members of the Society, in different parts of the Bengal Presidency, as well as by the Belgian Farmers. Specimens of the Flax produced having been sent to Calcutta, comparisons were instituted between the samples produced by different individuals, and those from European and from indigenous seed. Mr. Deneef, the Belgian farmer, pronounced the samples worth from £44 to £60 a ton; and some that was produced from country seed and heckled, was thought worth £66 a ton. Some of the specimens sent to Liverpool, were valued at from £30 to £45; and those which were forwarded to Dr. Royle by the Secretary of the Agricultural Society, were pronounced by Mr. Hutchinson, of Mark Lane, to be worth from £40 to £45 a ton. The experiments were made chiefly near Burdwan, Monghyr, and Shahabad; but the best native seed was obtained

from the northern station of Saharunpore, and a white Linseed from the Saugur and Nerbuddah territories. A little Flax was also produced by Mr. Williams, at Jubbulpore, under the direction of Mr. Macleod. Mr. Leyburn gave as the result of his experiments near Shahabad, that the expenses of culture of a bigah of land, and the preparation of the fibre, amounted to Rs. 25 1 a. 3 p.; and the profits to Rs. 27 1 a. 5 p., supposing the four maunds of Flax produced to be worth £35 a ton. In consequence of a communication which had been received from the Honorable Court of Directors, Sir T. H. Maddock, at that time Secretary to the Government of India, addressed a letter to the Agricultural-Horticultural Society. In this the Society was requested, in order to assist the Government in determining on the measures proper to be adopted for improving the cultivation of Flax, to supply such accurate, detailed information as they may possess, or as they may be able to obtain. The Society accordingly prepared a report which contained everything that was known at that time on the subject of the cultivation of Flax in India. This was forwarded to the Government, and also published in their 'proceedings' for Nov., 1841. In this report, the Society took a very favorable view of the probabilities of the profitable culture of Flax in India. The Revenue Secretary to the Indian Government, on this, wrote (November 22d, 1841) to the Agricultural Society, that—"The cultivation of Flax can no longer be considered a doubtful experiment, since it appears from your report to have proved in many instances successful; and where successful, to be very fairly profitable. His Lordship in Council is therefore much inclined to doubt whether any bounty or reward from Government is necessary, or would be justifiable." Notwithstanding this favorable inference, the Flax Company did not go on with the cultivation; the various individuals who had taken up the culture did not proceed with their experiments, the several medals offered by the Agricultural Society seem never to have been claimed, and there are no appearances of the culture of Flax on account of its fibre in any of the places where the experiments were made. It is probable, therefore, that the success which appeared sufficient when the experiment was of the nature of garden culture, was not realised when on a greater scale. M. de Verinne, indeed, states that the experiment in the seasons of 1840-41 was a complete failure at Bullea, owing to too little seed having been sown, to the unusually dry weather at the late sowings, and to the improper time (the hot winds) in which the Flax was cleaned. Mr. Wallace, who had carried on the cultivation for three or four years at Monghyr, writes on the 8th July, 1841: "The crop has been in a great measure a failure this year. About one eighth the produce that a favourable season would yield." But in the year 1844, he again forwarded samples to the Agricultural Society, which were improved in cleanness and were also softer than the produce of former years, from the same cultivation. These were portions of several tons that had been grown at Monghyr, and which he intended shipping to Dundee, the port to which his last batch was sent. But Mr. Wallace added, with regret, that after several years' labour, with a view to establish Flax cultivation at Monghyr, and after having taught the art of dressing the article to many parties, the speculation must be abandoned unless the Government gave some encouragement. He therefore requested the assistance of the Society in bringing the subject to the notice of the authorities. It is stated at a subsequent meeting, that the Committee of the Society, after being furnished with further details respecting the cultivation, did not feel inclined to refer the subject to the Government. But neither the details referred to, nor the reasons of the Committee for their decision are given, and, therefore, we are unable to ascertain the real causes of failure after several years' trial. Mr. Henly, an intelligent merchant from Calcutta, having made some careful experiments on the culture of Flax, furnished Dr. Royle with the following account: "I have paid much attention to the fibres during my residence near Calcutta, and, not wishing to conclude from hearsay only, generally cultivated most things myself, having a large piece of ground available. I sent up to Baugulpore (an excellent *Flax seed* district), and obtained a considerable quantity of native-grown Flax straw, after the removal of the seed. I had it collected from various fields, so as to obtain an average. This material was in every instance too *bushy* for the proper production of fibre, and the yield was very trifling, and in fact worthless for manufacturing purposes. The bushiness arose from the practice of the natives, who grow several plants, as you are aware, at once, in the same field. The Flax plants were consequently planted too far apart for fibre-yielding purposes. Not yet fully satisfied on the question, I took a patch of land (three cottahs), the best I could pick out, fine, friable loam, fit for anything—it had been a cauliflower bed, and was therefore deeply spade-cultivated and highly manured—its last crop, cauliflowers, having nothing prejudicial to a Flax crop. I began very early in the season, had it turned up and laid for a fallow; two months after, again pulverized and weeded; and again—four times in all; with the addition of a large supply of fine old cow-dung. I had it now sown in the proper season, with the best Flax seed, very thickly planted, so as to draw it up as free as possible from lateral branches. Everything promised well. The field grew beautifully, and soon attained a height of three feet. I began to collect the crop, first, as

soon as the flower had completed its growth and the seed-vessels began to form; secondly, as soon as the seed-vessels had fully formed, and were filled with green, but immature seeds; and lastly, after the seed was fully ripe. I took great pains in water-retting the samples—generally removing them from the water rather underdone, for fear of occasioning weakness in the fibre from over-retting. In every instance, the quantity of fibre was small and weak, and very inferior to the samples of Flax deposited at the Agricultural Society's Museum, obtained from Jubbulpore, and other upper-country districts. No Indian Flax, however, which I have seen, equals in nerve and general good qualities those of European growths." As the above is no doubt a correct account of what occurs with the Flax plant in the moist climate of Bengal, of which the effects may perhaps have been aggravated by too great richness of soil; it might be inferred, that a different result would take place in the drier climate of the upper or North-West provinces of India. This is certainly the case, but though the product is different, it is not, from the shortness and brittle nature of the fibre, more suitable for the ordinary purposes of Flax. Mr. Hamilton, of Mirzapore, one of the up-country stations alluded to, "sent some bales of the stalks to Calcutta, for the inspection of the Belgians, and was told that the shortness of the stalks would prevent their manipulation." It is evident, therefore, that there is some difficulty in producing good Flax in India. This difficulty is, no doubt, the climate; while the native methods of culture are the most unsuited to the production of good fibre. Mr. M'Adam, Secretary to the Royle Flax Improvement Society, has in his Prize Essay on 'The Cultivation of Flax.' well observed "that a slow, steady growth is requisite for the quality and yield of fibre; also a temperate climate, that between the parallels of 48° and 55° being the best; and a continued supply of moisture from spring till autumn." He also observes that "the hot summers of Russia and of Egypt cause a dryness and brittleness of fibre, and prevent its retaining that elasticity, pliancy, and oilness which characterise the Flaxes of Belgium, Holland, and Ireland." But considered generally, it is not to be expected that a plant which attains perfection in Belgium, and is so successfully cultivated in the vicinity of Belfast, would succeed well in the hot and moist, but sometimes dry climate of Bengal. In fact, if the Flax was not one of those plants which, like the cereal grains and pulses, can be grown in the cold weather months of India, it could not be cultivated there at all. But with this culture, we have the anomaly, of the seeds being sown in autumn, [In Egypt, also, the seeds are sown about the middle of November, in the plains which have been inundated by the Nile, and plucked in about 110 days.] when the climate is still hot and the ground moist, and the plant has to grow while the temperature is daily becoming lower and the soil drier—no irrigation being usually employed with these winter crops, though dew begins to fall as soon as the ground becomes cooled at night. In some places, the crop attains perfection in about ninety days, is collected in January, the coldest month; in others, not until February or March, when the rapid rise of temperature is favorable to the ripening of seeds, but not to the production of fibre. Of all parts of India there are none that appear to Dr. Royle better suited to the growth of Flax than the Saugur and Nerbuddah territories, as the soil is rich and prolific, and the climate a medium between the extreme moisture of Bengal and the dryness of the North-West provinces. The Wheat of this district is considered superior to any seen in the English market, with the exception of what comes from Australia. The Gram (*Cicer arietinum*) and the Linseed are also of finer quality than any produced elsewhere in India; while the suitableness of the climate for the production of good fibre is proved by the length and strength of the Jubbulpore Hemp, as grown by Mr. Williams; as well as by the specimens of Flax which he has likewise grown. The Indian method of culture is certainly not suited to the production of fibre, but the seeds abound in oil. "The yield of oil from a bushel of Indian seed is from 14$\frac{3}{4}$ lb. to 16 lb.; of English or Irish, 10$\frac{3}{4}$ lb. to 12 lb." Therefore, it is evident that the Indian ryut succeeds in his object, as well as the Irish farmer, who grows the Flax plant for its fibre, but neglects to gather the seed: though this is not only a saleable product, but one which abounds in nutritious matter for his cattle, and would further afford the means of fertilising his fields. As it has been found difficult to persuade the Irish farmer to gather the double crop, I believe it would be hopeless to induce the Indian ryut to change a culture which is suitable for his purposes, without the aid of successful example in his neighbourhood. You might make him grow less seed, but I much doubt whether we should get him to produce any useful fibre; and without his co-operation it would be impossible to attain any considerable success. Indeed, the Agricultural Society of India have given it as their opinion, in one of their resolutions,—"That the culture and preparation of Flax in India, so as to be able to compete with the Flax of Belgium or Russia, can only be effected by practical European growers instructing native cultivators in the art; and, further, that an entire change in the mode of cultivation, as well as in the preparation of the plant, is necessary to produce the article in a proper state." It has, indeed, been made a question, whether a good supply of fibre and of seed can be procured from the same crops.

One gentleman, in reply to my inquiry, informed me (London, 4th July) that "it has been found impossible to preserve both seed and fibre, *i. e.*, for the better qualities of each; and that the plan pursued is simply to gather before the seed ripens, when the delicacy and softness of fibre form the desideratum, but to leave the plant standing until the fibre is dried and greatly injured, in order to secure the superior seed fit for sowing;" and this is the result of information collected after a residence of many years in the interior of Russia. Another gentleman replies to the same inquiry, from Belfast, on the 8th July: "It is not only quite practicable to have good seed and good fibre at the same time, but it is the universal rule in all countries except Ireland, where we have only been able to get the more intelligent farmer to abandon the wasteful practice of steeping the Flax stems without removing the seed. The finest Flax in the world is grown in Belgium, yet the seed is saved from it." But as there is no doubt, from the experiments of the Indian Flax Company, and from other more recent facts, such as the production of Flax as far south as on the Shevaroy Hills, at Jubbulpore, and near Lahore, that Flax can be produced in India, it seems desirable to ascertain whether it cannot, by careful culture and improved processes, be produced as a profitable crop in some parts of the country; because, it cannot be thought that that which is done successfully in Egypt, is impossible in every part of India;" and there can be little doubt that, in some places, at least, coarse Flax could be produced, as well as some for the paper-makers. The Messrs. Hamilton, of Mirzapore, propose, in 1854, attempting the culture of Flax, in the tract of land of which they have a grant, in the Goruckpore district, and considered a more favorable locality than any near Mirzapore. Dr. Royle suggested that Mr. Williams, at Jubbulpore, should be requested to make an experiment, to ascertain the quality of the Flax which may be produced in that locality, as well as the quantity obtainable per begah or acre; attempting at the same time to preserve the seed. Mr. Williams has already grown a little Flax, he is accustomed to the preparation of fibre, and the soil and climate are both, he conceived more favorable than in most parts of India. He also recommended that Dr. Jameson, the Superintendent of the Botanic Garden at Saharunpore, should be directed to make a small experiment, both in the plains and in the hills, in order to ascertain the same kind of facts respecting the Flax plant when grown according to European methods for the sake of the fibre. The Agricultural Society of the Punjab have attempted the culture, and the Secretary addressed a letter to the Court, requesting an opinion respecting the quality of the Flax which they produced.

Observations on experiments.—On reviewing the accounts and the results of the Indian experiments, it appears that though abandoned too soon in some situations, they were carried on for a sufficiently long period in others to allow of reliable deductions being drawn from them, if full information on all points had been supplied. The soil does not seem to have been complained of; but though drainage is essential in many parts of Europe, the power of irrigating will be found most useful in the East. The climate is obviously very different from what the plant meets with in Ireland, as not a drop of rain seems to fall from the time of sowing to that of reaping the crop; but heavy dews compensate for this deficiency during a part of the season. But as this dryness of climate prevails over a great part of India during the season of cultivation—that is, from the end of the rainy season to the beginning of the hot weather—it is evident that irrigation is necessary for such cultivation, and must not be too expensive. Perhaps the double monsoon of the Madras Presidency might in some localities afford a suitable climate, if the temperature is not too high. A perfectly appropriate climate, may no doubt be obtained at different elevations on the Himalayas, and in some of the mountainous ranges of the South of India; but European superintendence may not be available and the expenses of transit be too great. The Saugur and Nerbuddah territories appear favorable, from their more moderate climate; while some of the districts of the North-West, of Sindh, and the Punjab, may be found suitable, from the command of irrigation and the prevalence of a moderate temperature. The proportion of seed required having been ascertained by Mr. Deneef, we cannot but observe the unexpected results obtained from the sowing of some native seed—the Flax produced from Saharunpore seed having been considered to be of excellent quality, and, in Liverpool, to be the best of all the specimens sent. American seed was found to be suitable to the country; but it is remarked that when sown in a rich, it did not do so well, as when sown in a poorer soil. The whole question of what is the best seed for the untried soils and climates of new countries is one of considerable difficulty. It does not follow that seed from a rich soil and the most careful cultivation is necessarily the best transference to a poorer soil and drier climate; indeed, the converse would, in many cases, appear to be the more suitable course. But even in the case of Wheats, some from Australia and from the Nerbuddah, pronounced the finest in the English market, have never produced good crops in England, notwithstanding the most careful attention. Indeed, the most advisable course appears to be to grow the best native seed, and as thickly sown as is found to be suitable, for the express purpose of changing the branching nature of the plant, and then making

an exchange with the seed of other districts following the same course; in order to insure that interchange of seeds which is so beneficial for all kinds of crops, and is conspicuous in India in the indigo crops of Bengal being grown from the seeds of the North-West. In the directions for culture in Europe, we have seen that early sowing is necessary to produce good fibre, and late sowing for seed; but in India the reverse course is to be followed, for early sowing, in consequence of the high temperature, induces rapid but, from the dryness of the climate, stunted growth with an abundant production of seed; while later in the autumn the temperature is lower, the growth is slower, but the dews being heavy, there is greater moisture, and this with the slower growth, produces finer fibre. The early sowing is preferred by some, in order to save the expense of irrigation, but this must sometimes be with the sacrifice of the quality of fibre. With respect to the cost at which Flax can be produced in India, we find Mr. Leyburn stating that he gets four maunds of Flax, or 328 lb., from about one third of an acre of land, at a cost of £2 10s., or for about £17 a ton; and that this sold for £28 a ton in London; but we do not find that he proceeded with the cultivation. Mr. Deneef calculated the cost of Flax produced by him to be £32 a ton, with a profit of £8, which would afterwards amount to £14. Mr. de Verinne calculated the cost would be £31 a ton, with an average crop; though he did not get half the quantity. The cost of both is evidently too high, unless the finer qualities of Flax are produced. Mr. Wallace who continued the longest, and produced Flax at the cheapest rate —that is, from £12 to £15—ought to have succeeded, as he states that the expenses of cultivation were paid for by the seed. But we find him, as we have already stated, representing to the Agricultural Society that he should be unable to go on with the culture, from the discouragements he had met with, unless assisted by the Government. Though the difficulties are not specified, they must have been greater than appear from the published accounts, and therefore the facilities and the profit are not so great as they appeared to the Agri-Horticultural Society,—who thus unintentionally induced the Government of Lord Auckland to consider that public aid was not necessary. It is very evident that such experiments can only be made under the superintendence of Europeans, when, if successful, they may be adopted by natives. In repeating the experiments in more favorable situations, it would seem very desirable at first to ascertain as accurately as possible the quantity of produce of ordinary quality obtainable per acre, with good cultivation in a favorable locality, on an average of years, and then to endeavour to improve the quality. The profits of the two kinds of cultivation and preparation are not very dissimilar in Europe. Though manufacturers may require more of the coarser qualities of Flax, planters will of course grow that for which they can get the best prices; though it will be safest at first to reckon only on getting the prices of Russian or Egyptian Flax. We may proceed now to inquire where else Flax may be cultivated in India.

Culture in Saugur and Nerbuddah Territory.—It has been mentioned that the central province of the Saugur and Nerbuddah territories seems well adapted for the culture of Flax, from the nature of the soil and climate. Here, indeed, some Flax has already been grown by Mr. Williams. This being the result of a first experiment, on a small scale, is not, perhaps, calculated to give a fair idea of what is practicable, particularly as we are without any information respecting the mode of culture, or the kind or quality of seed which was employed. But Mr. M'Leod, now Commissioner in the Punjab, mentions in one of his reports, that the growth is very luxuriant there. The Flax is comparatively short, light coloured, and rather dry, and more like Egyptian than any other kind of Flax. It might be objected to the growth of Flax so far in the interior, that land-carriage for so great a distance would be an insuperable obstacle. But, as Mr. Williams finds it suit his purpose to send his now-famed Jubbulpore Hemp even to Calcutta, there seems no reason why Flax should not be equally able to bear the expenses of culture and of transit. In this direction, there is, moreover, an excellent road, described by the Cotton Committee of the Agri-Horticultural Society, 8th January, 1840. "From Jubbulpore to Mirzapore, on the banks of the Ganges, the great cotton-mart of the North-West provinces, a bridged and metalled road of 239 miles in length, equal to any in England, has been made by Government; at all the stations, the means of transport, and on the river, boats of every description, abound." This road is regularly kept up, and a toll levied at the base of the ghauts. The native princes have, however, without contributing to its expenses, diminished its utility by levying extra duties on the goods passing through their territories. (*v.* 'Journ. Agric. Soc.,' vol. viii, p. 115. [See also a letter by Montague Gore, Esq., to the same effect, in 'The Times,' in the summer of 1853.] There is a prospect, however, of these being remodelled. The most important consideration, nevertheless, is that of the climate. According to the concurrent testimony of different observers, as reported in Dr. Royle's work, on 'The Culture and Commerce of Cotton in India,' p. 311, &c., deficiency of moisture is seldom complained of; and there will, probably, be seldom any excess in the season when the Flax would be cultivated—that is, in the cold-weather months. Hence the chief difficulty in India will be diminished, if not entirely escaped.

Culture in the Madras Presidency.—Good Flax has been produced still further south, where elevation produces lowness of temperature accompanied with moisture of the atmosphere, as on the Shevaroy Hills and on the Neilgherries. Dr. Cleghorn, Secretary of the Agri-Horticultural Society of Madras, is well qualified to give the best advice on localities where experiments may most fitly be tried; and Professor Mayer is there, to give the benefit of his chemical investigation of the Flax plant and soil. Mr. M'Ivor, in charge of the Public Garden at Ootacamund, is well situated for making experiments on the growth of Flax in the cool and moist climate of the Neilgherries, if the culture should in other respects appear desirable. Linseed has long been cultivated in the Madras Presidency, though not to any great extent. Dr. Ainslie mentions the seed under the name of *Aliverei*, and states that in the southern parts of the Peninsula, the Moochie men and oil painters make use of Linseed oil. But we now find Linseed among the Exports: in the year 1850-51, there were exported 801 cwt of Linseed from Fort St. George, nearly all to the United Kingdom.

Culture in Bombay Presidency.—In the Bombay Presidency, Linseed is also cultivated, as in all other parts of India, and has of late years been exported in considerable quantities. We observe that in the year 1850-51, 59,076 cwt., and in 1852-53, 162,915 cwt.= Rs 4,86,460, in value, were imported into Bombay from the Concan; and that there were exported to the United Kingdom, in 1850-51, 50,102 cwt., valued at Rs. 170,112, and in 1852-53, 114,309 cwt.=Rs. 342,926 in value. We do not observe that any attempts have been made to grow Flax. It is probable that the low country along the coast may be too hot, and the country above the ghauts to dry; but of this those who are located in these parts can most correctly judge, if it should be thought desirable to make the attempt. Col. Sykes describes Linseed as generally cultivated in the Dukhun. The export of Linseed from Bombay is now estimated at an annual value of about four lacs of rupees, although five years ago it did not exceed one lac. This the Chamber of Commerce ascribes to the improvements on the Thulghaut road, and to the consequent reduced cost of conveyance in carts instead of on bullocks..

Proposed culture in Bundlecund.—An article has lately appeared in the 'Benares Recorder' (15th July, 1854), proposing the culture of Flax and of Hemp in Bundlecund; observing that "with less capital than what English merchants now expend in Russia, India can produce Flax which will not be inferior in fibre or colour to the Riga Flax. In Bundlecund the soil is almost free and unoccupied; and the land rent is also so low, that failure in the cultivation of either of these two products—Flax and Hemp—would be impossible. There are numerous hill streams with clear water, over the whole country, that would admirably serve the purpose of steeping." But the great uncertainty is the climate, which, like the parts of the Gangetic valley which have been alluded to, is very dry during the season of cultivation. But it is certainly worthy of inquiry, by those favorably situated for the purpose, whether, by irrigation, or by the aid of the dew which undoubtedly falls in the cold weather, this dryness might not be sufficiently obviated to allow of the production of good Flax.

Culture in the Northern Doab.—The most northern station from which any Flax was sent during the experiments of the Flax Society was Allygurh, in 27° and 28° of north latitude. Mr. J. Saunders, on the 26th July ('Proceedings,' p. 100) wrote that he had sent a sample of the Flax which he had grown on the banks of the Kote Nuddee. But he described it as prepared with very clumsy tools, and cost him about four rupees a maund for merely breaking; as to scutching, it has had none. The finest seed was, however, obtained from Saharunpore in 30° of north latitude—a locality with which Dr. Royle is well acquainted, but where no Flax is produced, and where the soil and climate are dry during the cold-weather months and season of cultivation; that is, from October to March, with the exception of some rain at Christmas time, often called the *chota bursaut*. The district has, however, enjoyed the advantage of canal irrigation for more than twenty years, under the superintendence of Sir Proby Cautley, greatly to the benefit of the country and people. This would give great facilities for Flax cultivation, and would not be expensive. The experimental culture which has been sanctioned to be made by Dr. Jameson in the Botanic Garden at Saharunpore, as well as in the Himalayas, will no doubt be carried on with his characteristic energy. The experiment will be useful from the information which it will undoubtedly afford for comparison with those which have been made in Bengal and Behar, as Saharunpore is situated near the north-western extremity of the Gangetic valley, and the temperature is such that there is every prospect of the plant being slow in growth, and that, with the aid of canal irrigation, the growth will be such as to insure sufficient length of fibre. Of the temperature in the cold-weather months we may judge from the following, deduced from Dr. Royle's observations while he was Superintendent of the Botanic Garden; from which it will be seen that November would be the fittest month for sowing, and the crop could be gathered in February or March, before the heat becomes great.

Mean Temperature. See Report on the Botanic Garden at Saharunpore, 'Journ. of the Asiatic Society,' vol. i.

Oct.	Nov.	Dec.	Jan.	Feb.	March.	April.
74	64	56	52	56	67	78

In the Himalayas the season of cultivation is the same as in Europe; for there, as here, the winter months are too cold for the growth of plants—but the spring and summer temperature is exactly suited to the growth of an annual like the Flax plant.

Mean Temperature.

March.	April.	May.	June.	July.	August.	Sept.	Oct.	Nov.
53	59	66	67	67	66	64	57	50.

As far as temperature is concerned, there is evidently a long period for cultivation, and different months might be selected for the purpose. But there is a great difference in the moisture of the different months, as the rains come on in the middle of June, and are excessive for three months. But it would be interesting to ascertain the effects of such moisture on the growth of a fibre like that of Flax. It is probable that the plant would require to be supported, to prevent its being laid.

Culture of flax in the Punjab.—The Punjab, so recently acquired, is already as settled as any of the older provinces, in consequence chiefly of the energy and intelligence of the Service being applied to devising methods of Government suitable to the people and country, instead of attempting to introduce English institutions among the foreigners who are unable to appreciate or to take advantage of them. In the Punjab, we see some of those who were fighting against us, now employed in the far East with our own troops; but many being necessarily left without employment, are ready to take to or return to agricultural pursuits. The vigorous measures which have been adopted, while they give security and freedom of communication, will also greatly facilitate agricultural pursuits; especially as some of the public works in course of execution are canals of irrigation. There, the Kote Kangra valley teems with Chinese Tea shrubs, the first of which were planted in the year 1848, that is, immediately after the conquest of these hills by Lord Hardinge; and the Tea which has been prepared from these plants is considered to be of the first class of China Teas, by such excellent judges as the Messrs. Thompson. The culture of Silk has lately been introduced by the Agri-Horticultural Society of the Punjab—the first specimens having been sent to Calcutta and to England, were considered to be naturally of good quality, but very indifferently reeled. Mr. W. H. de Verinne having been sent up by the Government with an establishment of silk-winders and reelers from Morshedabad, and some samples of silk of their winding having been sent to Calcutta and to the India House, the former was pronounced by Mr. E. Kilburn, on 1st September, as "requiring only a little more attention to rank with the product of the best Bengal Filatures," and which would have been worth in May about Rs. 12 8 per factory seer. The specimens sent to the India House were submitted to the Messrs. Durant, who gave a most carefully drawn up report, and pronounced them excellent specimens of Bengal Silk, but requiring a little more care; and worth from 14s. to 15s. a pound in London. Vigorous measures have in consequence been adopted for the prosecution of the culture by plantations of different kinds of Mulberry, besides the kind which is already common in the country, which, in the opinion of Mr. de Verinne, is almost equal to the Bengal Mulberry. It is probable that some difficulties may be experienced from the dryness of the climate in the plains of the Punjab; but there can be none in the hilly districts where the Tea plant is flourishing. Some of the native Wools also having been highly approved of, twenty-five Merino Rams have been imported by the Government from Australia, for the further improvement of the breed of Sheep. That some parts of the district are well adapted for the production of fibres, is evident from the Kote Kangra Hemp proving one of the strongest of known fibres. The Agri-Horticultural Society of the Punjab, therefore, have begun their experimental cultures in a very favorable locality, from the great variety of soil and of climate within the command of their members. If the Geography of Plants and of Animals is attended to, as well as the Principles of Culture in new situations, little doubt need be entertained respecting the success of the above cultures as well as of Flax. Though Linseed is so extensively produced throughout India, we hear nowhere of the fibre being valued and separated. But when we get to the confines of cotton-producing districts—that is, into the Punjab—we find that some Flax, prepared by the natives on their own account, is separated in the neighbourhood of Lahore. For we are told that the stalks of the Linseed plant yield a fibre, which is made into twine, and used for the network of their charpaes or native beds. This information was elicited in consequence of inquiries originated by Mr. Frere, the distinguished Commissioner of Sindh from his desire to promote the culture of Linseed in the province under his charge. The fibre, however, of the Linseed plant is separated in still more northern parts, as some seed of Bokhara Flax sown in England was found to be that of the common Flax. The inquiries made respecting the growth of Linseed in the Punjab elicited the following facts: On the Cis-Sutlej it is stated that three seers to a begah are sown broadcast when alone, or in drills; probably as an edging to other crops. Three maunds of Linseed considered a good crop. The stalks and husks considered refuse and useless. The seeds sell for 18 seers for the rupee to oilmen. A maund of seed yields of oil 10½ seers; of oil-cake 29½ seers. The oil sells for 5 and 5½, and

the oil-cake at 60 to 66 seers for the rupee. In the Jalindhur Doab, Linseed is cultivated, especially in the Khadir or inundated land of the Beas and Sutlej Rivers; but plants always small; seed sells for 20 to 30 seers for a rupee. It is also cultivated in the Sheerwul, or tract of country in which the soil is firm and covered by a deposit from the rains, with the subsoil always moist—ripens before barley, and generally before wheat. Linseed is also cultivated in the rich loamy soils of the Kangra district skirting the Himalayas, but chiefly in the eastern parts, on account of the seed, which sells for 20 to 100 seers for the rupee—Flax itself burnt. In the Punjab, sown with barley and mussoor (or lentils) in Katick (Oct. and Nov.), and is ripe in Cheyt (March and April); usually sown intermixed with the above crops, or in separate patches. Never irrigated, but grown along the Sutlej, in Khadir land, or that which is inundated during the rainy season, but never manured. In the Lahore division, it is grown chiefly about Sealkote and Deenanuggur, and is the only part where the fibre seems to be made use of, as it is stated that the stalks yield a fibre which is made into twine, and used chiefly for the network of their charpaes or native beds. The price of the seed is about Rs. 2 8 per maund. Few localities are stated to be well suited to it, and the seed was in little demand. Twine made of the fibre was sent, but no notice seems to have been taken of its quality. From the above details of cultivation, it is evident that though Linseed is very generally known, it is nowhere extensively cultivated, as is evident from the price of the seed, which is dear in comparison with that of Wheat. Some of the uses are well known; for instance, the oil is used as a drying oil, and the bruised seed, mixed with flour, is described by Major Edwardes as given as a strengthening food for cattle, and the oil-cake is no doubt employed for the same purposes; while the fibre is sufficiently valued to be separated in some, though burnt in most other places. It would seem much in favour of the production of good fibre that the growth is much slower than in the southern provinces of Bengal. The Society began some experiments on the culture of Flax, in the cold weather of 1853, with seed obtained from Saharunpore; that is, the same place from which the best seed was obtained in the experiments in Bengal and Behar, and which produced such good Flax. (*v.* p p. 176 and 182.) The samples were prepared under the superintendence of Corporal Keenan, of H.M.'s 10th Regiment. Of the opinion formed of these samples when sent to Calcutta, Mr. Wood, Secretary of the Chamber of Commerce, writes: "7th June, 1854. The general opinion regarding the Flax is very favorable. It is considered the finest that has been ever grown in the country; and that the cultivation of it might be encouraged." Some of the Special reports are as follow: Mr. Stalkartt writes:—"This Flax is decidedly the best specimen of this country's growth, and I should say a good merchantable article. It is very difficult to give a thorough report upon it, as we have none from Europe to compare it with. From the test it did not appear very strong, and from its smell I should say that oil had been used in the preparation; perhaps with an improved method it would have greater strength, as oil, generally speaking, deteriorates greatly the strength of Hemp and Flax. I would like to see it in greater bulk; a handful is not a fair sample." Report from Mr. Haworth.—"Although I am not a member of the Flax and Hemp Committee, I am glad to have had the opportunity of examining the sample forwarded to the Society by Mr. Cope. On the whole, I think, its preparation does great credit to Corporal Keenan; any shortcoming is owing to the finer heckles not being ready. I think the length of fibre is good; the colour of the greater part is bright and healthy—that portion shows good strength; there is, however, a small part of the sample of a dark dull colour, which, I think, is caused by over-retting, and that portion of the sample is, as might be expected, weaker than the rest. If the natives of this country could produce such Flax as this specimen under notice, from the immense fields now grown in Bengal for seed only, what an enormous amount would be added to the value of our exports." Mr. Stalkartt is a rope-maker, of the firm of Messrs. Harton and Co., of Calcutta, and wished ten maunds to be sent to him by the quickest transit—bullock-train and steam-boat—in order to see what he could do with it in his own business. He wished also for "a couple of maunds of the two," as he thought "it might be useful for the railway." Mr. Stalkartt's remark about oil being used in the preparation, is referred to by the Secretary of the Society, and contradicted, "as no oil was used." It is probably an accidental testimony to the softness of the fibre, which, in most of the Flaxes from warm countries, is found to be dry and hard. The Sub-Committee appointed by the Society to draw up a proposition for Flax arrangements, submitted the following—

Suggestions regarding the improvement in, and increase of, the cultivation of Flax, or Linseed plant, for the sake of its fibre.

1st.—It is to be made generally known that a premium, of Rs. 500, has been sanctioned by the Supreme Government of India, to be given for the largest area of land that may be appropriated, in the Punjab and the Cis- and Trans-Sutlej States, to the culture of Flax, during the seasons of 1854-55, being not less than 25 acres in any one village.

2d.—A second premium, of Rs. 350, has been similarly authorised, for the next largest area so

cultivated, being not less than 20 acres, in any one village, and—

3d.—A third premium, of Rs. 200, is to be granted for the third largest piece, being not less than 15 acres in any one village; that is to say, the Government will award the first premium to any one land-holder, or village community of land-holders, who may, in his or their own village, cultivate, for the production of Flax fibre, ground aggregating, in the whole, 25 acres, or as much upwards as the owners may choose. Moreover, the Government of India have sanctioned the purchase, on behalf of the Society, of the entire crop of merchantable Flax, including the fibre, if of the required length, that may be produced in the Punjab, and to pay for it at the current market rate of the Flax seed, with 25 per cent. added for the fibre. It is to be a condition that not less than sixty Company's seers of Flax seed, be sown on each begah, cultivated with a view to competition; and that the growers be informed that Government is prepared to purchase the whole of the seed, and likewise the fibre, if of the proper quality, on the terms above stated, but that the authorities be instructed not to purchase such produce unless it measure, in in the stem, three and half feet in length or more; that it be well dried, and the seed just on the point of ripening, but not so ripe as to allow of its falling out of the pod by the way.

The directions for cultivation are as follow: If the following instructions are strictly attended to, here is no doubt that the Flax will all be of the required length of staple. Not less than sixty seers of Flax must be sown, broadcast, that is with the hand, on each begah, as the thicker it is sown the longer will be the plant, and the more free it will be from branches, which are very injurious. The land must be thoroughly freed from weeds by repeated ploughings previous to sowing; it must be well manured with the richest manure procurable, such as is given to land for tobacco; be smoothed, and divided into beds as for wheat. The seed must be sown between the 1st and 5th November, but not later. The Flax land must be watered as frequently as wheat-land; and the fields must be kept perfectly free from weeds until the Flax is six or seven inches high. After that, no more weeding will be required. The land selected should be light loamy soil; Khadir land is the best. When the seed begins to show signs of ripening, the Flax must be pulled gently by the root, and laid on the ground to dry in rows. When thoroughly dry, it must be tied up in the bundles as large as a man can conveniently span with both hands, and it can thus be easily measured. The seed can be stripped off (rippled) on arrival of the consignment at Lahore, and the final price be arranged according to the current rate of Linseed in the Lahore market. That is, if the successful, or any other, competitor (all

Flax will be bought that is of the required length, whether a premium have been awarded for it or not), who may deliver Flax, yielding 125 maunds of Linseed, will, if, as at present, the nerik be Rs. 2 8 a maund, receive Rs. 312 8 for the seed, and 25 per cent., or Rs. 78 2, additional, as compensation for the fibre, or Rs. 390 10 in all. It is to be understood that successful competitors are to be paid for their crop as well as others; but that no cultivators are bound to sell, should they wish to dispose of their crop in any other manner. It might be explained to the ryuts, that those who are not successful in growing Flax of the required length, will find a ready market for the seed in Mooltan, whence it will be conveyed to Sindh for export to England. It is further strongly recommended, as a new feature in the proposed measures, for improving the cultivation of this important staple, that the Society be authorised to hire, on behalf of Government, from 30 to 40 begahs of land, in the immediate vicinity of their garden, for the cultivation of Flax, during the coming season, so as to admit of a comparison being drawn between the Flax grown by the zumeendars and the plant reared under probably more favorable circumstances. The seed required for each begah, the purchase of which, it is hoped, the Government will also sanction, will be one maund and a half (at a cost of about Rs. 4), and the land is obtainable at Rs. 20 per begah; for which the cultivators undertake to perform all agricultural operations, such as ploughing, watering, weeding, sowing, and reaping, *for one year*—a plan by which the grower can ascertain the expenses of his crop to a rupee. It is strongly recommended to the Meeting that, in confident anticipation of the sanction of the authorities to this measure, which anticipation they venture to rest on the past liberality of Government, and the great importance of the subject, and also on account of the advanced state of the season, the Secretary be, at once, empowered to make arrangements for obtaining land. The vigorous proceedings of the Agri-Horticultural Society of the Punjab, and the ready patronage of the Government, including the purchase of the produce, ought to produce some decisive results, if the soil and climate are found to be favorable; and of this there can be little doubt, from Flax having been produced there in 1853 and from the description given of it by the members of the Hemp and Flax Committee of Calcutta. The specimens stated to have been forwarded to the India House have not been received. But while the best method of culture will be ascertained by the Society in their own cultivation, it is to be feared that the length of stem required (three feet six inches) will exclude much of what may be grown by the ryuts. The extension of the culture will no doubt reduce the price of the seed,

and enable it to be sold at such rates as to allow of its becoming an article of export to Europe. The Society having included in these recommendations an application for some tons of the best Linseed (mentioning especially the Belgian) as well as some tools, to be sent them, this was approved of, and forwarded by the Indian Government, in August, 1854; but as it was obviously too late for any large quantity of seed to be sent in time for the sowings of this year, small quantities were sent out by the overland route for the sake of comparison with the native seed, and also some tools as specimens. But as it is extremely doubtful what kind of seed will answer best in the soil and climate of the Punjab, it has been thought preferable to send the seeds of different kinds—as Riga, Dutch, American, English and Irish.

(3941) *Culture of Flax in Sindh.*—The province of Sindh, about 360 miles in length, extending from 23° 37 to 28° 32 N., consists of a delta of extensive alluvial tracts, intersected by numerous canals and water-courses, which enable cultivation to be carried on by irrigation; thus making up for the deficiency of rain. Though the temperature of a great part of the year is high, it is probable that that of the cold-weather months may be sufficiently low to allow of the successful cultivation of Flax and Linseed, at the same time with the Wheat, Barley, and Oil-seeds which form the Rubbee or cold-weather crops of Sindh, as of most parts of India. Indeed Mr. Frere, the enlightened Commissioner of Sindh, wrote to the Board of Administration of the Punjab, to have inquiries made throughout that territory on the extent and nature of the Linseed cultivation therein—the result of which inquiry has been given in the preceding pages. A commercial gentleman, to whom were referred the specimens of the Punjab Linseed, and the prices at which it was sold, observes "that there as in Sindh, the culture of it is altogether upon so limited a scale as barely to supply local wants and judging from the Rs. $5\frac{1}{2}\frac{1}{2}$ per maund quoted as its sale price in Lahore, with cost of carriage to Kurrachee, 800 to 1000 miles, would stand us higher than the ruling rates in Bombay." "The quality of the Linseed" he considered "good and such as would command the highest prices in Mark Lane, which average about 48s. per quarter." Upon this, Mr. Frere justly remarks that "the present prices of an article, which is at present grown in small quantities merely for local consumption, afford no means of judging of the price at which it can be profitably grown in large quantities for exportation; and, looking at the way in which it usually flourishes in wheat-land in India, at the present prices of wheat, I feel little doubt but that it can be grown very cheaply in many parts of the Punjab and Sindh. The facilities which exist for water-carriage down the Indus will render its transport cheap; while great and constant demand exists for it in Bombay. "I think, therefore, that it is an article to which attention may be profitably directed in any district where it is desirable to discover articles of produce adapted for exportation." The Bombay Chamber of Commerce observe: "Linseed of the quality described as the growth of the Punjab would, under all ordinary circumstances, command a ready sale in this market, at from Rs. 3 4 to Rs. 3 8 per cwt. of 112 lb.; and during the greater part of the past year the price has been as high as Rs. 3 12." Dr. Royle has been favoured with a letter (dated 19th August, 1854) from Mr. Frere, in which he states that—"For the last two seasons attempts have been made, with very satisfactory results, to introduce the culture of Linseed into Sindh. It grows well in the ordinary wheat-lands, and under every disadvantage, there has been no failure traceable to soil or climate. I have no doubt but that, in a few years, it will become one of the staple articles of export." He also states that attention has begun to be directed to the fibre, and that Mr Harvey, who was in early life practically engaged in Flax farming in Ireland, and who has now been some years resident in Sindh, has commenced some experiments, and hopes to be able this season to send to this country some specimens of Flax grown in Sindh. In a previous page it was mentioned that Mr. Burn, who had been some years in Sindh, had seen some thick-sown Flax, growing there luxuriantly and of which he had no account of the seed. Some Europe seed, for the sake of comparison with the native seed, and some heckles which Mr. Harvey wished for, have been, at Mr. Frere's request, forwarded, by order of the Court of Directors, by the overland route to Kurrachee. There seems no doubt of success to at least the same extent as in Egypt, if the culture is persevered in until the proper methods of cultivation and of preparation have been carefully ascertained.

Exports of Linseed from India.—The large exports of Linseed from India have frequently been mentioned. It is desirable, therefore, to give some of the details. By these we may observe, that though comparatively a recent trade, the article is already known to other countries besides England. The first Export of Linseed was made from Calcutta by Mr. Hodgkinson,

In the year	1832,	to the extent of	10 bushels, and increased
„	1833	„	2,163 maunds.
„	1834	„	2,826 „
„	1837	„	32,327 „
„	1839	„	167,601 „
„	1850	„	765,496 „

As the details of this export may be interesting, we subjoin the following table of the Im-

ports of Linseed and Linseed Oil into, and Exports from, the three Presidencies:

Linseed Oil Imported (1850-51)	Into Calcutta.	Into Fort. St. George.	Into Bombay.
From United Kingdom ...	Rs. 7,984	—	—
„ Amsterdam	805	—	—
Linseed Imported—			
From Concan	—	—	Cwt. 59,076
Value	Rs. 8,739	—	Rs. 201,035

Linseed Exported (1850-51) from	Calcutta	Fort St. George.	Bombay.
To United Kingdom,	Ms. 298,005	Cwt. 797	Cwt 50,102
„ North America,	421,407	—	—
„ France,	44,986	—	—
„ Guam,	56	—	—
„ Rotterdam,	500	—	—
„ Mauritius,	60	—	—
„ New South Wales,	74	—	—
„ Trieste,	384	—	—
„ Penang,	24	—	—
„ Ceylon,	—	4	—
„ Concan,	—	—	10
Total	Ms. 765,496	Cwt. 801	Cwt. 50,112
Value	Rs. 1,530,902	Rs. 2,271	Rs. 170,539

But the commerce of Linseed has since then much increased; amounting in 1852-3, for Bombay, of Linseed imported, to 162,015 cwt., and of exported, to 114,379 cwt.

Quality of Linseed Oil of India.—It may appear remarkable that Linseed Oil should be imported into Calcutta, when so much Linseed is exported for the express purpose of yielding its oil. This is in consequence of the Linseed Oil of India being considered as not possessed of the full drying properties of the oil prepared in Europe. But there is no doubt, this is owing entirely to the Indian Linseed being expressed before the Mustard seed has been separated, with which it is commonly mixed, in consequence of the two plants being often grown together. Mr. Bowen informed the author that, when connected with one of the lighthouses in India, he had at one time under his charge some plate glass. This he made use of to separate the two seeds, by placing it on a slope: the round seeds of the Mustard rolled off, while the Linseed merely slipped down. These, when expressed, yielded as good drying oil as any he ever obtained from Europe. The same fact is confirmed by the following statements. In a report from Mr. W. Ewin, Branch Pilot, to Capt. W. Hope, Master-Attendant at Calcutta, he acknowledges the receipt of five gallons of Linseed Oil, made at the Gloucester Mills, situated below Calcutta. "I beg leave to say I painted my boat inside green with the above oil, without the assistance of turpentine, and it dried within the space of twenty-four hours; and do not hesitate to say, if the above oil agreeable to the master, be given, that it is equal to the Linseed Oil received from the Honorable Company's

Marine Yard, said to be Europe. "Sandheads, H.C.P.V. *Sea Horse*, 2d January, 1837." So Mr. W. Clark, commanding H.C.F.S.V. *Hope*, writes, 14th Dec., 1836: "I have to report, for the information of the Master-Attendant, in reply to his letter (No. 39) of the 7th ult., that I have painted the *Hope*, outside, with the Gloucester Mill oil on one side, and that supplied by the Naval Store Keeper on the other,—both laid on at the same time; and of the two I must give the preference to the former, in drying and bearing a better gloss."

Account of the quantities of Flax, Tow, and Linseed, imported into the United Kingdom during the year 1851, *distinguishing the countries whence they were imported, and the quantities brought from each.* (*M'Culloch's 'Com. Dict.'*)

(3942) FLEABANE, PURPLE.

Kalee-zeeree, Duk. Guz
Buckchee, Hind.
Kanana-iraka, Sans.
Caat-siragum, Tam.
Adavie zeela kara, Tel.

Are small dark-coloured, and extremely bitter seed, which are considered as powerfully anthelmintic; and are also an ingredient of a compound powder prescribed in snake bites by native practitioners. An infusion of seed is also given for coughs, and against flatulency.—*Ainslie.* These seeds are procurable in all Indian bazars.

(3943) FLINDERSIA, possesses a volatile oil. *F. Australis* is a native of Australia, and its wood is said to be not inferior to mahogany. *F. Amboinensis* is a native of the islands of Hitu and Ceram. The spiny part of the fruit is formed into rasps. It was on this account called by Rumphius *Arbor radulifera.*

(3944) FLINTS.

Pierre a fusi, Fr.
Feuerstein, Ger.
Chuchmuck, Guz. Hind.

A mineral composed almost entirely of silica. Few parts of the world are without it. It is used, when calcined and ground, in pottery; also for gun-flints, for which purpose the yellowish-gray flints are preferred.—*Waterston.*

(3945) FLORIKIN, OR FLOYERKIN.

Warroogoo koli, Tam.

This beautiful, speckled, greyish colored bird

which is common in almost every part of the Peninsula, is considered as a species of Bustard; it is reckoned, when dressed, a great delicacy by Europeans and gets its Tamool name from being usually found in the Warroogoo (Paspalum Frumentceum) fields.—*Ainslie's Mat. Med. p.* 297.

(3946) FLOUR.

Tringoo-pittay, CYNG.	Farina, LAT.
Bloem, DUT.	Flor de farine, PORT
Fleur de farine, FR.	Godhuma pishta, SANS.
Feines mehl, GER.	Flor, SP.
Atta. GUZ. HIND.	Godum-bay-mao, TAM.
Fiore, IT.	Godumapendie, TEL.

The meal of wheat finely ground, and sifted. —*Faulkner.*

(3947) FLOWERS.

A select list of popular Flowers cultivated at Madras.

A.
Ageratum.
Aster.
Allamanda.
Angeloen.

Jaffrey.

In addition to the above flowers, &c. we may add the fragrant smelling Maroodanie or Iveny (Lawsonia spinosa); the beautiful purple and fragrant Padriepoo, (Bignonia chelonoides) which is also a Pagoda flower; the sweet smelling Mara Malliepoo, (Millingtonia hortensis,) the produce of what is improperly called in English the Cork tree; and the Vatte Cheddie, (Justicia picta), a shrub admired for its beautiful, variegated, green and white leaves.—*Ains. Mat. Med. p.* 165. Mr. Fortune speaking of Foo chow foo says the celebrated fingered-citron, so common in the shops throughout China seems to be cultivated in great perfection in this part of the country, in fact, it appears to be its natural locality. The district round Foo Chow-foo seems to be the great Camellia garden of China, and in no other part of the country did he ever see these plants in such perfect health or so beautifully cultivated. The Ixoras and Hydrangeas are also particularly well grown and handsome, the latter invariably producing flowers of the deepest blue, much deeper than he had ever seen them in England. They are grown in a fine rich loam, which contains some chemical ingredient, and whichis the cause of their deep colour.—*Fortune's Wanderings, p.* 382. Early in spring the hill sides were covered with a beautiful Daphne with lilac flowers (Daphne Fortuni Lindley): Azalea ovata Lindl., certainly one of the finest and most distinct plants of this kind which he has introduced, also grows wild on the hills, and was in full bloom at this period. A fine new Buddlea (B. Lindleyana) had a most graceful appearance, as its long spikes of purple flowers hung in profusion from the hedges on the hill sides, often side by side with the well known Glycine senensis. Another plant, certainly one of the most beautiful shrubs of northern China, the Weigela rosea, was first discovered in the garden of a Chinese mandarin near the city of Tinghœ on this island. This spring, it was loaded with its noble rose-coloured flowers, and was the admiration of all who saw it, both English and Chinese. I have great pleasure in saying that all these plants and many others natives of Chusan are now growing in our gardens in England.—*Fortune's Wanderings, page* 317. In the hedges the last fading blossoms of the beautiful spring flowering Forsythia viridissima were still hanging on the bushes, with several species of wild roses, Spiræa Reevesiana, clematises, and Glycine sinensis, were just coming into bloom. But look a little higher up to that gorgeously painted hill-side, and see those masses of yellow and white flowers, what are they? The yellow is the lovely Azalea sinensis, with its colours far more brilliant and its trusses of flowers much larger, than they are ever seen in any of our exhibitions in Europe. The white is the little known Amelanchier racemosa. Amongst these and scattered over the hill sides, are other azaleas having flowers of many different hues, and all very beautiful.—*A Residence among the Chin. page* 27.

(3948) FLOWER BATTEN (76). A very hard, fine, close-grained heavy Ceylon-wood. Its polished surface shows a pleasing mottled pattern.

(3949) FLUOR SPAR, Derbyshire Spar, Native Fluoride of Calcium. A mineral found in great beauty and abundance in Derbyshire and other places. It is procured in cubic crystals of various colours, and in the Odin mine in detached masses, from an inch to more than a foot in thickness. This variety admits of being turned in the lathe into vases and other ornaments. Fluor-spar is also sometimes used as a flux for promoting the fusion of other minerals.—*Waterston. Foulkner.* Mr. Mason has a small specimen of bluish crystals of fluor spar, which the Burman, who brought it, said was found in the northern part of Province Amherst. As the mineral is often found in connection with lead, it is probable they will be found together in the Tenasserim Provinces.—*Mason.*

(3950) FLUGGEA VIROSA, Hamilton. *Syn.* Phyllanthus virosus, *Roxb.* p. 659. A middle sized tree in the Circar mountains, a large shrub in the plains; bark a strong astringent, intoxicates fish if thrown into the waters they inhabit. —*O'Shaughnessy, page* 552.

(3951) FŒNICULUM, a genus of Exogenous Plants belonging to the natural order *Umbelliferæ* to which the common herb called Fennel belongs. It was formerly considered a species of *Anethum*, but since the remodelling of the natural order *Apiaceæ* by Koch, it has been universally looked upon as a distinct genus. *Anethum* in fact belongs to the sub-division *Peucedaneæ*, with thin flat fruit, while *Fœnculum* forms part of *Seselineæ*, the fruit of which is tapering or very little compressed, and by no means flat. *F. vulgare*, is a biennial plant with leaves cut into hair-like segments, yellow flowers, and glaucous stems. The fruit is ovate, not quite two lines long, pale bright-brown, smooth, the ridges sharp with but little space between each, the lateral ones rather the broadest, terminated by a permanent conical disc. Common on chalky cliffs in the southern parts of England, and everywhere cultivated for the sake of agreeable aromatic quality of its leaves. Oil of fennel is obtained from the fruit. —*Eng. Cyc.*

(3952) FŒNICULUM DULCE, (Sweet fennel.) Seeds also afford a valuable essential oil, much used in medicine.—*O'Shaughnessy, p.* 360.

(3953) FŒNICULUM PANMORIUM.

Panmuhori, HIND.

Indian fennel seeds.—*Ben. Ph.* 208. *F. Panmorium* is cultivated in various parts of Bengal, under the name of Panmuhuree, or Mudhoorika in Sanscrit. Its fruit has a warmish very sweet taste, and aromatic smell, and is much used by the natives with their betel and in their curries. The root is white, nearly fusiform, and almost simple; the stem is erect, branched from the base to the top, from 2 to 4 feet high, the branches erect, round, and smooth, with a uniform pale-glaucous tinge and not striated. The umbels are terminal, rather concave, but not regular; the flowers small, bright deep-yellow, the petals long, ovate, with their points rolled in. The stamens longer than the petals. The fruit is used medicinally in India as a warm aromatic and carminative.—*Eng: Cyc.*

(3954) FŒNICULUM VULGARE, (Common fennel.) Europe. *Syn.* Anethum Fœniculum.

Shohie-keeray, TAM.

An essential oil is prepared in large quantities from the seeds. The odour of the entire plant is strong and persistent, that of the roots disappears on drying. The *essential oil of fennel* is clear yellow, easily frozen, lighter than water; sp. gr. 990. Fennel, used as seasoning by the natives, and by Europeans in garnishing is common in gardens, raised from seed.—*O'Shaughnessy, page* 360. In compounding *Confection of black pepper.* in India, forelecampane root (inula helenium), Dr. O'Shaughnessy recommends the substitution of the goonch root, Abrus precatorius. The Edinburgh Pharmacopœia uses liquorice root: and for the fennel seeds of the London preparation, the seeds of Panmuhori, or Sonf, (Fœniculum panmorium) are an adequate substitute.—*Beng. Phar. page* 273.

(3955) FOOD. The materials taken into the system of organised beings, and by which their functions are maintained, and out of which their bodies are formed, are called Food. Food in its widest sense is the raw material out of which plants and animals are manufactured. We shall confine ourselves here to the consideration of the food of animals, and of man in particular. The great cause of the necessity of a constant supply of new matter or food to the body is the waste of the materials of which the blood and organs are composed, during the performance of their functions. The result of this waste is seen in the form of the various excretions which are thrown off from the body by the skin, liver, kidneys, and bowels. We shall find, then, that the food, the blood, and the excretions, represent each other, that they contain substances of the same nature, and are all composed of the same ultimate elements. If we take a portion of human flesh or blood, and seek for its ultimate elements, we shall find that, on accurate analysis, they will yield the following elements:—

Carbon.	Potassium.	Aluminum.
Hydrogen.	Sodium.	Copper.
Nitrogen.	Calcium.	Chlorine.
Oxygen.	Magnesium.	Fluorine.
Sulphur.	Iron.	Silicon.
Phosphorus.	Manganese.	

Few or none of these elements occur in the human body in their pure form, but are combined variously with one another, forming compounds having very different physical properties and chemical relations. These elements may be divided, for physiological purposes, into two classes; the first four, carbon, hydrogen, oxygen, and nitrogen, being called Organic, whilst the remainder are called Inorganic elements. The first are called organic elements because they are found universally present in plants and animals, and because no animal cell and no vegetable cell can grow unless the whole of these elements exist. Hence, as they lie at the foundation of all organic existence, they are properly designated by this term.

The substances belonging to this group which enter into the food of man are cellulose, starch, sugar, and oil. Cellulose forming the external membrane of the cells of all plants is found in all food derived from the vegetable kingdom. It

has a composition almost identical with starch, but differs in being insoluble and indiffusible in water. There can be little doubt however that it is taken up extensively into the system in the food of the lower animals, especially of the *Herbivora*. When cells are very thick with cellulose they are indigestible, and this will account for many articles of food as carrots, turnips, radishes, uncooked vegetables, &c., not being readily digested. Cellulose is converted into starch by the addition of sulphuric acid, and it is not improbable that some change of this sort may take place when it is taken into the stomach. It is however seldom taken by human beings alone, although recommended by no less an authority than Benjamin Franklin, who showed by example that saw-dust pudding might be used as an article of diet. Starch enters very largely into the diet of man, and of the lower animals. It is distinguished from cellulose by its ready diffusibility in water. On this account it appears to be much more readily absorbed from the stomach or converted into the forms in which food is taken up into the system. Its property of uniting with water and forming with it at a high temperature a gelatinous mass, explains the change which takes place in boiling the flour of the grains in which it is contained. Starch is found in some plants in greater quantities than in others; it is however very generally found in perennial roots and rootstocks, in the stems and in the seeds of plants. There are few or no vegetables or parts of plants that are eaten that do not contain starch. It is found in turnips, carrots, potatoes, cabbages, parsnips, beans, peas, wheat, barley, oats, and the rest of the *Cerealia*; in chestnuts, walnuts, hazel-nuts, and all other seeds; in the apple, the pear, the plum, and cherry, and all other fruits. In many of these things however it is not the distinguishing alimentary ingredient, but it is often separated, and is used pure as an article of diet. The substances in which it occurs pure are arrow-root, sago, and tapioca. What is sold under the name of arrow-root, proper, in the shops, is a form of starch procured from the rootstocks of various species of plants belonging to the family *Marantaceæ*. See ARROW-ROOT. Although there is much difference in the price of arrow-root, its composition is always the same. Even the substance used to adulterate arrow-root, as potato and sago starch, are of the same composition; and though the appearance and flavour of the arrow-root may be impaired, its ultimate dietetical action is the same. Although arrow-root, sago, tapioca, and potato starch, are all composed of the same constituent, their flavour is very different; hence the preference given to arrow-root as an article of diet. This flavour depends on some peculiar principle which is produced in the plant from which the starch is obtained, and by very careful preparing can be entirely got rid of. Arrow-root is used for making cakes, puddings, and a thick gelatinous fluid in great request in the sick room. It is a property of starch to combine with water at a temperature of 180, and form a gelatinous compound. This property of starch renders it very useful in cookery, and seems to increase the digestibility of the starch itself. Arrow-root is frequently regarded as nutritious; but it will be seen that it is not nutritious in the proper sense of that word. Those foods can alone be called nutritious that contribute to the building up of the fabric of the body by adding those materials to the tissues which are being constantly removed by the wear of the body. Now starch does not perform this function, and is entirely consumed in the body in maintaining its animal heat. Arrow-root however and the other forms of starch, are frequently mixed with nutritious matters, such as milk and bread; and in this way the food into which they enter becomes nutritious. Another form of starch is Sago. It is starch obtained from the inside of the trunks of palms, and other trees. Many plants yield starch in their stems, which, on being prepared, is called sago by Europeans. The sago which is sold in the shops of England is principally imported from the islands of the Indian Archipelago, and is the produce of a palm called the true Sago-Palm, or *Sagus lævis*. There is however another palm belonging to same genus the *S. Rumphii* (the prickly Sago-Palm,) which yields the sago that is consumed by the natives of India. Sago is not generally so carefully prepared as arrow-root, and it is a much cheaper article of diet. Its ultimate action is perfectly the same as arrow-root. It is now often employed by starch-makers to procure the finer kinds of starch used by manufacturers. When thus prepared, it is used to adulterate arrow-root. Tapioca is another form of starch. It is brought to Europe from South America, and is the produce of a plant known to botanists by the name of *Janipha Manihot*. It is poisonous plant, and the Indians in the countries where it grows extract a posion from it, which they use to poison their arrows, before they obtain the starch. Cassava, which is eaten by the natives, is procured from the same plant, but is prepared in a different way from tapioca. The starch of tapioca does not differ in chemical composition from that of sago and arrow-root, and it is used in the same way, and for the same purposes. There are many other well-known plants which owe their dietetical properties to the starch they contain; amongst these we may mention the potato, the carrot, the turnip, the parsnip, the cabbage, the Jerusalem artichoke. From any of these starch might be prepared. The roots of *Arum maculatum*, though acrid, contain much starch. When cooked, the acridity of the plant is got rid of, and they are eaten with impunity.

These roots are employed in making the substances called Portland sago, which is the starch separated from the rest of the matter of the plant. This sago is used for the same purposes as the other kinds of sago. The roots of *Orchis mascula*, which is a common plant of our meadows, form the substance called salep. When it is boiled, it forms an agreeable article of diet, which, before the introduction of tea and coffee, was very generally used in this country. It is now almost entirely disused in Great Britain. Starch differs in some of its chemical and physical properties according to the plants whence it is obtained. In this way chemists have distinguished several kinds of starch. Inuline is a form of starch obtained from the *Inula Helenium*, a plant not uncommon in the English fields. Lichen-starch is another form, which is found in almost all kinds of *Algæ* as well as Lichens. This starch has the same power of thickening water at a high temperature as arrow-root and tapioca; and hence, when any of these plants are boiled in water, they form a thick mucilaginous decoction. The thickness of the fluid thus obtained, under the erroneous notion of its being nutritious, has led to the use of many species of sea-weeds and lichens as articles of diet. One of the plants of this kind, which has been used most extensively and is still largely employed, is the Iceland-Moss (*Cetraria Islandica*). It belongs to the family of Lichens, and is a native of the northern parts of the world. This and other lichens probably contain other dietetical secretions besides starch, as we find they are capable of supporting animal life. The Rein-Deer-Moss (*Cenomyce rangiferina*) is an instance of this. In the northern parts of the world as well as in mountainous districts this lichen grows in great abundance, and during the winter season is the principal support of the rein-deer. In spite of the extreme cold to which it is subjected this plant grows with vigour, and the rein-deer, in order to obtain it as food, is obliged to remove with its nose the snow with which it is sometimes covered for many feet. The Cup-Moss (*Cenomyce pyxidata*) of English moors belongs to the same genus as the rein-deer-moss, and is also used as an article of diet in the same way as the Iceland-moss. The tripe de Roche is another of these lichens which has been used as an article of diet. It has a melancholy interest attached to it, as it has so often formed the chief article of diet of our arctic navigators. Two species of lichens, the *Gyrophora proboscidea* and *G. erasa*, afford the Tripe de Roche. Although they are said to be nutritious, they are described as having bitter, nauseous, and purgative properties. Amongst the sea-weeds which have been used as articles of diet none is better known than the *Chondrus crispus*, which under the name of Carrageen-Moss, Irish Moss, and Pearl-Moss has been for a long time used in Europe. It grows on the rocky sea-shores of Europe; and when washed and dried, and then boiled with water, makes a mucilaginous decoction, which, like the same preparation of the Iceland-moss, has been recommended in consumption, coughs, diarrhœa, and other diseases. It has however no bitter principle, and is probably less tonic than the lichen. This and other sea-weeds have been occasionally had recourse to by the poor inhabitants of the sea-shores of Europe, more especially Ireland, when the ordinary corn or potato crop has failed. They contain however but little nutritious matter, and persons soon famish who live upon nothing else. There are certain forms of sea-weed which are often eaten as an addition to other kinds of food. There is in all of them a certain flavour of the sea, arising probably from the saline matter they contain, which renders them very objectionable to some persons as articles of food, and which will probably always form an objection to their general use. Of those which are eaten in various parts of England we may mention:—1. Laver, Sloke, Slokam (*Porphyra laciniata*). It is on all those sea-shores; and when employed as food is salted and eaten with pepper, vinegar, and oil. 2. Green Laver, Green Sloke, Oyster-Green (*Ulva latissima*). The *Ulva* is not so good to eat as the *Porphyra*, and is only had recourse to when the latter is not abundant. 3. Tangle, Sea-Ware, Sea-Girdles, Sea-Wand, Red Ware (*Laminaria digitata*). It is cooked by boiling for a long time, and adding pepper, butter, and lemon-juice. Cattle are fed on it when young in some parts of the British Islands. 4. Badderlochs, Hen-Ware, Honey-Ware, Murlins (*Alaria esculenta*). The part of the plant which is eaten is the thick middle rib which runs through the frond. It is sometimes called the Eatable Fucus. 5. The Dulse of the south-west of England is the *Iridea edulis* of botanists. It is eaten by the fishermen of the south-west coasts of England, who before eating it pinch it between red-hot irons. In Scotland it is cooked in the frying-pan. It is said to resemble in its flavour roasted oysters. 6. Dulse of the Scotch, Dellisk, Dellish, Duileisg, Water-Leaf (*Rhodomenia palmata*). The Highlanders and the Irish, before the introduction of tobacco, were in the habit of drying this weed and using it as a masticatory. The Icelanders use it as an article of diet under the name of the Sugar-Fucus. In the islands of the Mediterranean Archipelago it is employed as an ingredient to flavour soups, ragouts, and other dishes. Several other sea-weeds have been employed as food, but these are the principal that are at present used in Britain. In China the people are very fond of sea-weeds, and many kinds are collected and added to soups, or are eaten alone with sauce. One of these, the *Plocaria tenax*, is sometimes brought to England under the name of Chinese Moss. The de-

coction it makes is so thick that it is used as glue. The Corsican Moss, which has a reputation in medicine as well as a diet, is the *Plocaria Helminthocortos*, and is found on the coasts of the Mediterranean. Another sea-weed was recently imported into London under the name of Australian Moss; but although affording a very thick jelly, it tastes too strongly of the sea to be rendered pleasant by any kind of cooking. The next dietetical substance of which we have to speak is Sugar. Sugar is distinguished readily from starch by many properties. Sugar is soluble in water, whilst starch is only diffusible through it. Sugar is susceptible of fermentation, and of being converted into alcohol, which starch is not. Sugar has a peculiar sweet taste, whilst starch is insipid. It is on account of the solubility of sugar that we never, or very seldom, find it in plants in a solid condition. It is always dissolved in the water naturally contained in the plants in which it exists. Sugar is not so frequent a product of vegetable change as starch; but is, nevertheless, very generally found during some period of the growth of the majority of plants. Sugar, like starch, is not nutritious, but is taken into the system with the object of maintaining animal heat. Persons may even get fat on sugar, but the living tissues are not nourished by any of the carbonaceous productions of plants. It is true, that in countries where the sugar-cane is grown, slaves and their children, during the period of its gathering, partake of it in large quantities, and are nourished upon it; but the sap of the sugar-cane, and the cane itself contain other alimentary principles besides sugar, which assist in the nutrition of the body. Although there are various kinds of sugar, having a different composition, they seem all to act dietetically in the same way upon the system. The most common form of sugar in plants and that which is most frequently eaten in diet, is Cane-Sugar, so called from its being yielded by the sugar-cane. It consists of—

	Atoms.
Carbon	12
Hydrogen	9
Oxygen	9
Water	2

The other kinds of sugar which are eaten, are milk-sugar, $C_{24}H_{18}O_{18}+5HO$; and grape-sugar, $C_{12}H_{12}O_{12}+2HO$. It will be seen that cane-sugar resembles starch in its composition, and it is probably formed in the plant from that body. Although cane-sugar is found in the sugar-cane, the beet, and the maple, it is not so frequent in plants as grape-sugar, which is the form in which sugar is found in the fruits and other parts of plants which may be sweet. The sources of sugar, as an article of diet, are of course very various; it is only separated however from a limited number of plants. Of these the principal is the sugar-cane (*Saccharum officinarum*.) The sugar eaten by the inhabitants of France is principally obtained from the Beet (*Beta vulgaris*). In tropical countries it is obtained from the juice of palms, as from the Jaggary Palm (*Caryota urens*), the Cocoa-Nut Palm (*Cocos nucifera*), and others. It exists in the stems of all grasses, and is prepared in America from Maize (*Zea Mays*). The Birch (*Betula alba*) in England. and the Sugar-Maple in America (*Acer saccharinum*), also yield it in their sap. Grape-sugar, also called Glucose, is found in the fruits of most plants. It seems to act on the system in precisely the same way as cane-sugar. The result of the fermentation of grape-sugar is the production of Alcohol, which does not differ much in composition from sugar. The following is the decomposition:—

	C.	H.	O.
2 Atoms of Alcohol... ...	8	12	4
4 Atoms of Carbonic Acid.	4	0	8
2 Atoms of Water ...	0	2	2
One Atom of Grape-Sugar	12	14	14

Alcohol is taken as an article of diet in the forms of beers, wines, and spirits. Although resembling sugar in its composition, its effects on the system are very different. It acts on the nervous system as a stimulant and narcotic, and might perhaps be regarded as one of the medicinal forms of food. A question has arisen amongst physiologists as to the action of this substance on the system. Liebig, and with him many others, maintain that like starch and sugar and oil, the elements of the alcohol unite with oxygen in the system, and thus by combustion assist in maintaining animal heat. On the other hand Dr. Carpenter, and those who repudiate the use of alcohol in diet, maintain that it is not destroyed during respiration, and consequently does not promote animal heat any further than as it stimulates the heart's action. Alcohol when taken as an article of diet not only acts upon the nervous system, but on account of its chemical action on albumen exerts an injurious influence when taken in large quantities upon the mucous membrane of the stomach. It is thus that when indulged in, it becomes a source of indigestion, and lays the foundation of serious diseases. Taken in small quantities in the form of wine or beer, it seems to exert a favourable influence on the digestive function, and to belong to that class of foods to which spices and condiments are referred. Taken medicinally it is often capable of exerting powerful effects, on account of its rousing action upon the vascular system. It does not seem to be necessary to health, as there are many nations that never use it, and individuals, in countries where it is habitually taken as an article of diet, find their health not materially injured by debarring themselves from its use. The quantity of alcohol contained in fermented be-

verages varies very much. With regard to wines, when the juice of the grape contains large quantities of sugar in comparison with the water, and the fermentation is complete, then the alcohol is abundant, and strong wines are produced; whilst, when the sugar is in small quantities, or the fermentation is incomplete, weak or thin wines are the result. Ports and sherries are strong wines, whilst those of the Rhine are generally weak. Sweet wines are those in which all the sugar is not converted into alcohol. This is mostly the case with wines made from other fruits besides grapes. Hence the well-known sweetness of what are called British wines. This does not however arise from an imperfect fermentation, but from the acid contained in other fruits not being tartaric acid. One of the most remarkable properties of tartaric acid is that it forms an insoluble salt (the cream of tartar) with potash, which is generally found in fruits; and in wines made from the grape this salt falls to the bottom of the cask, forming the tartar or lees of the wine. But other acids, as citric, malic, and oxalic acids, are not thus precipitated from their solutions, and they remain in wines, giving them a very acid flavour, which would render them unpleasant, unless sugar was added to cover the acidity. Sweet wines are objectionable as articles of diet, on account of the sugar they contain, which, when held in solution in wine, seems more likely to decompose, and thus prove injurious to the system, than when taken in its pure form. In wines made from other fruits besides grapes, the acid is also liable to objection. Effervescing wines are those which are bottled before the fermentation is complete, so that a large quantity of the carbonic acid, which would be otherwise got rid of, is retained in solution in the wine, and escapes when the bottle is uncorked. Such is champagne. Effervescing wines are more liable to disagree with delicate stomachs than others, on account of their imperfect fermentation rendering them liable to further change in the stomach; and this state of change is probably communicated to the substances used as food contained in the stomach. The skins and stalks of the grapes, if not the juice, contain tannin. This substance is a powerful astringent, and its presence seems to be the cause of the astringent character of many red wines, as port, claret, and others. There is also a difference in the quantity of free tartaric acid contained in wines; and those which have the largest proportion of this constituent have an acid flavour. Some of the wines made from grapes are so sour as to be very unpalatable: this is more especially the case with the poorer white wines of the Rhine. The quality in which wines differ from each other most is what is called their bouquet, or flavour. It differs in wines made from different kinds of grapes, and differs in the same grape in different districts and in different seasons. It is well known that the vintage of one year produces a better or worse wine than that of another, and this depends on the development of the peculiar flavour of the wine. Liebig says that the bouquet is dependent on an acid which he calls œnanthic, and which, combining with the alcohol, forms an ether which gives the odour and flavour to wines. The quantity of alcohol contained in wines differs very much. The ports and sherries consumed in England contain the largest quantity. But then much of this is added. It is added in the form of brandy. Brandied wines keep best, but are not the best to drink. Unless wines are naturally strong, they will not keep without the addition of alcohol. Clarets, hocks, and Moselles, are seldom brandied. Some of the hocks do not contain more than seven per cent. of alcohol, whilst port and sherry contain twenty-five per cent. Ardent spirits, distilled liquors, differ from wine in their having been submitted to distillation after the fermentation, which produces the alcohol. Brandy is distilled from wine; and beech-kernels, or other vegetable matter containing oil of bitter almonds, are added to give it a flavour. All the parts of the plants belonging to the division of the order *Rosaceæ*, called *Amygdaleæ*, contain oil of bitter almonds. Rum is distilled from molasses or treacle in the West India Islands, and pine-apples are added to give a peculiar flavour. Gin is distilled in Holland, from rye; in this country from wheat, the grains of which are allowed to become saccharine, and then fermented. Juniper berries are employed to give the peculiar flavour to gin. Whiskey is distilled from wheat, barley, or oats, treated in the same manner as for gin. Nothing is added to flavour it; but the smoke of the peat, by the aid of which the distillation is effected in both Ireland and Scotland, gives a characteristic flavour to this liquor. Liqueurs belong to this division; they are distilled spirits containing large quantities of sugar, and are flavoured with all kinds of substances, as celery, bitter almonds, gentian, wormwood, &c. Beers, Ales, and Porters, differ from wines in the addition of a bitter principle, most frequently the hop, to the fermented liquor. The saccharine matter for fermentation is obtained through barley. The grain of barley is steeped in water, and allowed to germinate. When the starch of the grain is converted into sugar, it is submitted to heat, and malt is formed. The malt is placed in boiling water, and hops added; when cooled, the process of fermentation is allowed to take place, and the beer is completed. When the malt is slightly charred during the process of drying, it gives a dark colour to the beer. It is then called porter. These fluids vary much in strength and bitterness, according to the quantity of malt and hops employed. Beer is the safest of these beverages for habitual use; but even this may be indulged in too freely, and

disease may be the result. Of the various kinds of beer, that which is to be most commended, is the weak form of bitter ale, which is now so generally employed in the households of London and its neighbourhood. Beer acts as a tonic on account of its bitter principle, as well as a stimulant, and is frequently, on this account, found to be a valuable addition to the ordinary diet. The Oleaginous Group of foods is somewhat peculiar. They are taken in various forms from both the vegetable and animal kingdoms, and are known under the name of butter, oil, lard, suet, fat, &c. The following formula will express the composition of this class of bodies :—

Carbon	11
Hydrogen	10
Oxygen	1

It will be seen that the oxygen is in considerably less proportion than in the foregoing substances of this group, and we may consequently conclude that the hydrogen as well as the carbon is consumed in the system in maintaining the animal heat. This is an important point, as it frequently happens that the value of the heat-giving group of foods is estimated by the quantity of carbon alone. That oil has more power in maintaining animal heat than sugar or starch, is seen in the fact that it is eaten in larger quantities by men who live in cold regions than by those who live in the warmer parts of the earth. Just as we pass north or south from the tropics, man adds oil to his food according to the degree of cold to which he is exposed. Oil seems also to be deposited in the tissues of man and other animals as a course of combustible materials when these fail in their natural food. Thus the *Ruminantia* get fat in summer to supply them with their winter's store of fuel. Hybernating animals, which are fat when they commence their sleep, wake up quite thin. Their fat has been exhausted in maintaining their animal heat during hybernation. Oil performs another function in the system. It is very evident from its general presence in every tissue of the body that it has an action in connection with the development of the proteinaceous tissues. It seems to assist their development, to act as a kind of preparation for their growth. In this way its curative action in certain forms of disease may be explained. There is no doubt of the beneficial action of cod-liver oil in scrofulous diseases, and its action can only be explained on the above supposition. In connection with the use of cod-liver oil it may be stated that animal oils appear to be in a different physical condition of aggregation from vegetable oils, and are certainly more readily digested and appropriated by the system. The vegetable oils chiefly used as food are those obtained from the Olive (*Olea Europæa*) and the Almond (*Amygdalus dulcis*). Many seeds, as the Cocoa-Nut (*Cocos nucifera*), Almond (*Amygdalus*), Chestnut (*Castanea*), Walnut (*Juglans*), Hazel-Nut (*Corylus*), Brazil-Nut (*Bertholletia*), contain oil. The fat of animals is the great source of oleaginous food from the animal kingdom. We now come to speak of the Nutritious, Proteinaceous, or Nitrogenous articles of diet. The substance called Protein is the basis of these. It is the first element that appears in the development of the vegetable cell. It is consequently universally present in plants. It also constitutes the chief material of the tissues of animals. It assumes in both kingdoms various forms, and is called albumen, fibrine, and casein, according to its physical and chemical properties. Some animals derive this constituent of their bodies directly from the vegetable kingdom, as all the herbivorous and gramnivorous creatures; others derive it indirectly from the plant through the animal, as the various forms of *Carnivora*. Man obtains his supply of protein from both sources. As a sect has arisen of persons who deny the propriety of man's taking animal food, it may be well to examine the evidence on which his claim to be regarded as a flesh-eating animal rests. We shall dismiss the sentimental objection, that life ought not to be taken as unworthy of serious refutation, as every one must feel that for carnivorous animals to prey upon lower animals is a natural law. It will be gathered from the foregoing general remarks that food may be divided into two great classes—the heat-giving and the flesh-forming; and we now present a table of some of the more ordinary kinds of food, in which one or the other, or both, of these classes of substances are found mixed :—

Table of Composition of Food in 100 *parts.*

Food.	Quantity of Nitrogenous Flesh forming Ingredients.	Quantity of non Azotised Heat giving Principles.	Quantity of Mineral Matter.	Quantity of Carbon.
Milk	4·50	7·90	0.60	6·94
Butcher's Meat free from bone	22·30	14·30	·50	21·56
Bacon, Pork...	8·36	62·50	0·50	53·92
Fish	14·00	7·00	1·00	9·15
Flour	17 00	66·00	0·70	45·50
Barley Meal	14·00	68·50	2·00	40 50
Oatmeal	13·60	70·30	3·30	44·10
Indian Meal	10·71	72·25	1·04	36·41
Peas	23·40	60·00	2·50	35·70
Rice	5·43	84·65	0·52	36·00
Potatoes	1 41	22·10	1·00	12 20
Carrots	1·48	11·61	0·81	5·40
Turnips	1·64	10·00	1·62	5.20
Parsnips	2·10	17·70	0·80	8·68
Mangel Wurzel	1·60	12·26	1·14	5·50
Cabbage	1·75	4·05	2·20	2·65
Cocoa (nibs)...	9·56	85·76	2·70	68·56
Sugar	0·00	100·00	0·00	42·58
Suet, Fat, Butter... ...	0·00	100·00	0·00	79·00
Bread	6·83	48·65	1·51	25·19
Cheese	31·02	25·30	4·90	36·30
Beer	·85	9·17	0·20	4·33
Vinegar...				

Such a table as this will be found useful in constructing dietaries for large institutions, which are very often erroneously constituted, and a large waste thereby entailed. The table on the next page contains examples of dietaries, drawn up by Dr. Lyon Playfair, from various sources. This table accompanied an abstract of a lecture by Dr. Lyon Playfair on the 'Food of Man,' delivered at the Royal Institution in May 1853. The following extracts from this lecture will explain some of the valuable results obtained by Dr. Playfair:—"It was now admitted that the heat of the body was due to the combustion of the unazotised ingredients of food. Man inspires annually about 7 cwt. of oxygen, and about 1-5th of this burns some constituent and produces heat. The whole carbon in the blood would thus be burned away in about three days unless new fuel were introduced as food. The amount of food necessary depends upon the number of respirations, the rapidity of the pulsations, and the relative capacity of the lungs. Cold increases the number of respirations and heat diminishes them; and the lecturer cited well-known cases of the voracity of residents in arctic regions, although he admitted, as an anomaly, that the inhabitants of tropical climates often show a predilection for fatty or carbonaceous bodies. He then drew attention to the extraordinary records of arctic dietaries shown in the table, which, admitting that they are extreme cases even in the arctic regions, are nevertheless very surprising. "Dr. Playfair then alluded to the second great class of food ingredients, namely, those of the same composition as flesh. Beccaria in 1742 pointed to the close resemblance between these ingredients of flesh, and asked, 'Is it not true that we are composed of the same substances which serve as our nourishment?' In fact the simplicity of this view is now generally acknowledged; and albumen, gluten, casein, &c., are now recognised as flesh-formers in the same sense that any animal aliment is. "The old mode of estimating the value of dietaries, by merely giving the total number of ounces of solid food used daily or weekly, and quite irrespective of its composition, was shown to be quite erroneous; and an instance was given of an agricultural labourer in Gloucestershire, who in the year of the potato famine subsisted chiefly on flour, consuming 163 ounces weekly, which contained 26 ounces of flesh-formers. When potatoes cheapened he returned to a potato diet, and now eats 321 ounces weekly, although his true nutriment in flesh-formers was only about 8 or 10 ounces. He showed this further by calling attention to the six pauper dietaries formerly recommended, to the difference between the salt and fresh meat dietary of the sailor, &c., all of which, relying on absolute weight alone, had in reality no relation in equivalent nutritive value.

"Taking the soldier and sailor as illustrating healthy adult men, they consumed weekly about 35 ounces of flesh-formers, 70 to 74 ounces of carbon, the relation of the carbon in the flesh-formers to that of the heat-givers being 1 : 3. If the dietaries of the aged were contrasted with this it would be found that they consumed less flesh-formers (25—30 ounces), but rather more heat-givers (72—78 ounces); the relation of the carbon in the former to that of the latter being about 1 : 5. The young boy about 10 or 12 years of age consumed about 17 ounces weekly, or about half the flesh-formers of the adult man; the carbon being about 58 ounces weekly, and the relations of the two carbons being nearly 1: 5½. The circumstances under which persons are placed influence these proportions considerably. In workhouses and prisons the warmth renders less necessary a large amount of food fuel to the body; while the relative amount of labour determines the greater or less amount of flesh-formers. Accordingly it is observed that the latter are increased to the prisoners exposed to hard labour. From the quantity of flesh-formers in food we may estimate approximately the rate of change in the body. Now, a man weighing 140 lbs. has about 4 lbs. of flesh in blood, 27½ lbs. in his muscular substance, &c., and about 5 lbs. of nitrogenous matter in the bones. These 37 lbs. would be received in food in about eighteen weeks; or, in other words, that period might represent the time required for the change of the tissues, if all changed with equal rapidity, which is however not at all probable. "All the carbon taken as food is not burned in the body, part of it being excreted with the waste matter. Supposing the respirations to be 18 per minute a man expires about 8·59 ounces of carbon daily, the remainder of the carbon appearing in the excreted matter."

When human milk is examined, it gives the following results in every 1000 parts:—

Water	870
Butter	52
Sugar	63
Casein	10
Salts	5
	——1000

These five constituents of milk may be regarded as typical of all kinds of food, whether obtained from the animal or vegetable kingdom. Hence, we may class alimentary substances according as they are represented by one or other of these constituents of milk.—*English Cyclopædia.*

FOOD PLANTS.

(3956) FOOD PLANTS. With a rapidly increasing population in all parts of the world, the production of bread is obviously an object of the first importance, to all classes and the vegetable substances, from which man derives his principal sustenance, necessarily occupy the main attention of the cultivator, while their products form a most important staple of domestic and foreign commerce. In the four years ending 1852, the annual quantity of corn, of various kinds, imported into the United Kingdom, exclusive of flour, and meal, rice, sago, &c. averaged 8,085,903 quarters. The flour and meal imported, omitting sago, arrowroot and other starches, averaged in the same period 4,143,603 cwts. annually.—The following lists of cereal grains and pulses, will give the names of the food plants cultivated in the Madras Presidency.

Botanical Name	*English Name.*	*Hindustanee Name.*	*Tamil Name.*
Hordeum hexastichon,	Barley,	Jow,	.....
Triticum aestivum,	Wheat,	Gihoon,	Goodoomay.
Eleusine coracana,	Raggy,	Natchnee ragee,	Kavaroo.
Oryza sativa, varieties,	Common rice, Black, Red,	Chawul, Paddy, &c.	Areesee,
Setaria italica,	Italian millet,	Kala-kangnee,	Tenney,
germanica,	German millet,	Kora kang.	
Panicum miliaceum,	Common millet,	Sawee, cheena warree,	Varugoo.
Pencillaria spicata,	Spiked millet,	Bajree,	Cumboo.
Sorghum vulgare	Great millet,	Jowaree,	Cholum.
Zea mays,	Indian corn,	Mukka Jowaree Boota,	Muka cholum.

PULSES CULTIVATED IN MADRAS AS FOOD FOR MAN OR BEAST.

Botanical Name	*English Name.*	*Hindustanee Name.*	*Tamil Name*
Medicago sativa,	Lucern,		
Trigonella fœnum graecum,	Fenugreek,	Maitee or meetee kee bajee,	Vendium.
Psoralea corylifolia,	Hazel-leaved psoralea,	Bawurcheen,	Karpooga Arisee.
Cicer arietinum,	Chick pea Bengal gram,	Chenna,	Cadalei.
Ervum lens,	Lentil,	Mussoor,	Mussoor purpoo.
Pisum sativum,	Common pea,	Buttani,	Puttani.
Phaseolus vulgaris,	French bean,	Bakla,	French beansoo.
Phaseolus lunatus,	Duffan bean,		
—— radiatus,	Green gram,	Haree moong,	Putcha payroo.
—— mungo,	Moong or monash	Marh,	Oolandoo.
Dolichos uniflorus,	Madras gram,	Kooltee,	Kolloo.
—— sinensis,	Chinese dolichos,	Suffeed lobeh,	
Lablab vulgaris,	Bullar,	Saim ka puttee,	Motchay cottay
„ „ var.		Suffed,	Vellay mochay.
Psophocarpus tetragonolobus,	Winged pea,	Pank ke mutur.	
Canavalia gladiata,	Sword bean,	Lal kudsumbah,	Segapoo Thumbetten
Cajanus indicus,	Pigeon pea,	Toor dhal,	Thovaray purpoo.
„ var,	Dholl,	Lal thour,	Segapoo Thovaray.
„ „		Pad ka thour,	Malay.

Exports from Madras, of Food Substances for 1853-54.

Plants cultivated for Food, Oil, &c., in Pegu.

Esculent Vegetables.

Solanum melongena, brinjal. Khayan.
Solanum lycopersica, tomato or love apple. Thayan-myai-bone
Amaranthus polygamus, green Bajee, for vegetable curry.
Amaranthus atropurpureus, purple ditto.
Ocymum vilosum, mint for ditto. Penzeing.
Hibiscus sabdariffa, red sorrel or roselle for curry. Chin-boung.
Hibiscus longifolius, another variety for ditto. Kazoon-o-u.
Batatas edulis, sweet potatoe. Myouk-nee.
Dioscorea purpurea, purple yam.
Dioscorea glabra, the smooth ditto.
Dioscorea rubella, the red ditto.
Dioscorea anguina, the snake ditto.
Jatropha manihot, the Cassava yam.
Hedysarum tuberosum, the Batraj ditto.
Arachis hypogea, the earth nut. Myai-bai.
Dolichos catjang, long or French bean.
Dolichos lablab, the Indian ditto.
Raphanus sativa, or radish. Moue-lah.
Trichosanthes anguina, the snake gourd. Pailin-moay.
Momordica charantia, or small ditto. Kyet-bin-ga.
Luffa pentandra, the five-cornered ditto. Tha-boot.
Luffa decandra, the ten-cornered ditto. Tha-boot-khawai.
Lageneria vulgaris, the cuddoo or bottle ditto. Boo-shin-sway.
Lageneria pipo, the pumpkin.
Lageneria melo-pipo, or squash.
Arum furfaraceum, scaly yam.
Cucumis usitata, large cucumber. Tha-khwa-gyee.
Cucumis sativus, common ditto. Tha khwa.
Cucumis citrullis, or water-melon. Hpayai.
Allium cepa, the onion. Kyet-thoon.
Capsicum purpureum, red pepper. Gua-yoke.
Capsicum minimum, small or bird's eye pepper.
Andropogon esculentum, or lemon grass.
Cannabis sativa, or bang. Baing.
Nicotiana, tobacco. Hsai.
Piper betel. Koon.

Oil Seeds.

Sinapis dichotoma. Moung-ugyeen.
Sesamum muralis. Huan.

Grains and Pulses.

Phaseolus mungo, green gram. Pai.
Eleusine corocana.
Zea mays, or Indian corn. Pyoun-boo.
Oriza sativa, or rice of numerous kinds. Htson.—*McClelland.*

(3957) FORESTS OF TIMBER IN INDIA. A vast extent of Forest land in Oude, situated on the East side of the Kowreala river, was described by Dr. Royle, as holding out the prospects of very valuable supplies by the year 1850, provided that means were adopted for preventing wanton destruction, and of allowing the young plants to grow up, and supply the place of those which are cut down; but what has been the result, is not known. Among the forests in our own provinces, Dr. W Wallich adverts particularly to those occupying the Islands of the Gogra, commonly called Chandnee Choke. He represents them as extremely important, and in every way deserving of being preserved for the

exclusive use of Government, and especially of being emancipated from the destructive depredations which are annually committed. The Sissoo and Saul forests of the Deyra Doon are also recommended to be preserved for the use of the service; though from these the facility of transportation is represented as not equal to that from the other quarters previously mentioned. But they are nevertheless as important for the stations in the north-west of India, as the forests of Oude and Gorukpore are for those in the south. The Coast of Malabar has long been famous for its forests, especially those of Teak, of which the timber has always been remarkable for its superiority to that of other places, and with which the dock-yards of Bombay, as well as of Calcutta, have been long supplied. The quantity, however, has of late diminished, from the forests being partially exhausted, and pains not having been taken to keep up a supply. The Teak was also long ago pointed out by Dr. Roxburgh as abounding on the mountainous parts of the Coromandel Coast and on the banks of the Godavery, above Rajamundry. It extends also far into Central India, though there it is very dwarfish in size. It was planted in the Calcutta Botanic Garden, and plantations were established at several places in the interior of the Bengal Presidency. A new supply was, however laid open, on the acquisition of the territories along the East Coast of the Bay of Bengal. The forests to the eastward of the Saluen river, in Martaban, when visited by Dr. Wallich, were very favourably reported on, for the supply of splendid Bamboos as well as of Teak, for the extent of forests, the size of timber, and the facility of procuring it, as the timber could be procured within two miles of the river. Teak is not generally considered of so good a quality as that of Malabar, probably owing to its being produced on an alluvial soil, while the former is the produce of a mountain range.—*Royle's Productive Resources of India.*

Forests of Pegu and Tenasserim, White Wood.—Eighty-five species are soft and useless, being only fit for fuel. Many of them however are valuable, either for their fruit, gums, oil-seed or spices; others, for their close and compact structures, are employed in the manufacture of small ware, as a species of *Nauclea* used for making combs, and two species of *Erythrina* yield the light charcoal employed in the manufacture of gunpowder. These light woods useless as timber, belong to the families of *Urticaceæ* (including more than twenty species of *Ficus*,) and *Sterculiaceæ*, *Laurineæ*, *Rubiaceæ*, *Myristicaceæ*, *Anonaceæ*, *Spondiaceæ* and *Bignoniaceæ*, with odd species from other families. The remaining white woods, twenty-five in number, valuable for their strength and closeness of grain, demand a more extended notice. Seventeen of these are fit for house-building, and eight, from the hardness and fineness of their grain, render them valuable as fancy woods for cabinet making.

Red-colored woods.—These are twenty-five in number, seven of which, from their strength and solidity, are adapted for the various purposes of house-building; seven, from the elegance of their grain and colour, are suited to the various purposes for which mahogany is used, and eleven are suited to the finer purposes of fancy cabinet work.

Yellow Woods.—These are three in number, hard and fine grained, and suited to fancy purposes.

Dark-brown Woods.—These are twelve in number, and are all valuable. Eleven are adapted for house-building, and probably for ship-building, and one for special purposes requiring great strength and hardness.

Black Woods.—These consist of four different kinds, all of which are valuable for their strength and hardness.

Light-brown Woods.—There are seven varieties of this colored wood, embracing all the timber of most value in the Province, exclusive of Teak. (*McClelland.*)

(3958) FORMICA, a genus of Insects belonging to the family *Formicidæ*. It is distinguished by having the foot-stalk of the abdomen composed of a single joint, the mandibles triangular, and denticulated at the edge. The females are destitute of a sting. This genus comprises about a dozen British species, the largest of which is the Hill-Ant or Horse-Ant, *F. rufa*. The neuters in this species are about one-third of an inch long, of a black colour, with the thorax, abdominal scale, and a large part of the head, red. It makes its large conical nest in the open ground in woods, &c., amassing together large quantities of sticks, straws, &c.—*Eng. Cyc.*

(3959) FORMICA INDEFESSA, an exotic species, is described by Colonel Sykes as being an extraordinary instance of the operations of instinct in so low a form of animal life. The fondness of these insects for sweet substances is very great, and their attacks on such things were resisted in every possible manner, yet although the table, on which the confectionary and sweets were, was placed with its legs in water and removed a short distance from the wall, they succeeded in reaching them, to the great astonishment of all, until the mode of access was discovered. Colonel Sykes says, "I observed an ant upon the wall about a foot above the level of the sweets; it fell, and instead of passing between the wall and the table and alighting upon the ground it fell upon the table." Others followed its example with similar success; and it was no longer a matter for doubt as to how they continued to swarm in such numbers about their favourite food, however carefully guarded.—*Eng. Cyc.*

(3960) FORMICIDÆ, an extensive family of Hymenopterous Insects, belonging to the section

Aculeata, and to the sub-section *Heterogyna* of Latreille, comprising the Linnæan genus *Formica*, or the numerous tribes of ants. The family is distinguished by the wingless state of their abortive females, by the great length of the basal joint of the antennæ in the females and the neuters, in which they are elbowed at the extremity of this joint, and by the first or the first and second joints of the abdomen being knotted; the upper lip of the neuters is large, horny, and perpendicular, falling between the jaws; the eyes are rounded, or oval and entire; the jaws are large in many of the species, the form of these organs varying greatly in many of the species. In their structural character the *Formicidæ* resemble the *Tiphiæ* and *Doryli* belonging to the section of the Sand-Wasps. The neuters are smaller than the males, and these are smaller than the females; the abdomen in the first and last of these sexes is composed of six segments, in the male of seven. The females and neuters are furnished with a sting in many of the species. Those species which have stings emit an irritating fluid into the wounds which they make, while the stingless species discharge a red transparent fluid on to the skin, causing painful blisters. The various genera of this family, according to Latreille, are:—*Formica*, *Polyergus*, *Ponera*, *Myrmica*, and *Atta*. This last genus differs from *Myrmica* only in having very short palpi; the head of the workers is generally very thick. *Acephalota* is the Visiting Ant of the West Indies. [ANT; FORMICA; POLYERGUS; PONERA; MYRMICA and ATTA.]

(3961) FORGET ME NOT.—Myosotis.

(3962) FOSSIL COPAL was first found in the Blue Clay at Highgate, near London; it occurs also at Wochlow in Moravia and on the Western coast of India. It occurs in irregular pieces or small nodular masses. Its colour is yellowish or dull brown; nearly opaque. Lustre resinous. Fracture conchoidal. Specific gravity 1·046. When heated it yields an aromatic odour, and melts into a limpid fluid; it burns with a yellow flame and much smoke. When strongly heated in contact with the air it is totally dissipated.—*Eng. Cyc.*

(3963) FOURCROYA GIGANTEA. Nearly allied to the Agave, is the Fourcroya or Seemay, Cathalay, this fibre is of 5 or 6 feet in length a little finer than the Agave fibre, but possessed of similar properties. Good samples were exhibited by Mr. Jaffrey from the Horticultural Garden; by the Bangalore Local Committee; the Madura Local Committee; and the Madras School of Arts. The plant is one of the largest of its class, the leaves often attaining the length of 10 feet, but it is not so abundant as the Agave, though as easily propagated.

(3964) FOX. The Fox of the Himalaya, makes a near approach to the European Fox, though considered to be of a different species.

(3965) FRAGARIA, ROSACEÆ. The Strawberry.—This plant multiplies itself from runners and suckers; the old plant, after it has ceased bearing, throwing them out. As soon as the rains have set in, these runners may be removed into a nursery bed, for their being more easily looked after, and should have the space of nine or ten inches allowed between them; they will throw out other runners, the whole of which may be separated and transplanted at the proper season. They thrive best in a light soil with good old stable and vegetable manure at first, and as soon as they show a disposition to flower, may have old goats' or sheep's manure added around each plant, a couple of double handsful being sufficient. In no part of the Deccan, should the plants be put out for fruiting before the close of the rains, the latter part of September being quite early enough. Suckers I planted for experiment at the commencement of August, grew to a good size, and did nothing for ten or twelve weeks but throw out suckers, which were continually removed, and after all fruited badly: the finest and most prolific crop were got from suckers put out in the beginning of October. Some strawberries were gathered in November from the plants put out in August, but they were so few as in no way to induce a trial of the experiment again. Varieties can only be procured from seed; and to procure the seed, select the finest ripe fruit, rub it on a sheet of paper, and dry it. When the rains commence, soak the seed in water, reject all that float, the remainder sow in baskets in a light loam, when they will be fit to remove in about six weeks, and should be put in other baskets four or five inches apart, and taken care of until ready to be transplanted into beds, where they are to remain. As these plants throw out suckers very fast, they must be constantly looked after, and removed unless you have a scarcity of plants. They will commence bearing in six months from the time of sowing the seed. You may, as soon as the rains have ceased, put your suckers that have rooted into square beds, each not less than one foot apart, five in a row: this will give you twenty-five in each bed—as many as can be easily looked after and gathered without trampling on the bed and thereby injuring the plants. When the earth is of a clayey consistence, Dr. Riddell has seen the strawberry cultivated on ridges. Some think this is a good plan, but he prefers the beds: however, it can be easily tried. It is sometimes necessary, in consequence of flooding the beds, to put tiles under the fruit to keep it clean, but it also attracts the notice of the birds: if straw or grass be used, then the chances are that white ants destroy your plants. This it is that makes some persons prefer the ridge system of growing, as they say the fruit is cleaner in consequence: all he knows is, that fine fruit may be grown either way; and if on ridg-

es, the same distance must be allowed between the plants as in beds—and even in the latter the plants may be put on raised cones of earth. The common vegetable manure is all that is required at first until near flowering, when a handful or two of goats' or sheep's dung should be put round the plant, opening the earth and scraping it together. Water during the evening and very early in the morning.—*Riddell.*

(3966) FRANCOA. FRANCOACEÆ. *Francoa Appendiculata.*—These are beautiful plants when in flower, and may be planted out in the open garden, they can be only cultivated by seed.

(3967) FRANKINCENSE, Species of Boswellia Serrata. Roxb.

Koondricum, TAM.	Coondoor, DUC.
Encens, FR.	

Frankincense, a resinous substance, the produce of the *Abies excelsa* (De Candolle), the *Pinus abies* (Linn.), Common Spruce-Fir, from which it either exudes spontaneously or more abundantly from incisions of the bark. When it first flows out it is liquid, but on exposure to the air concretes, and is collected during autumn and winter. It occurs in two states, in tears (*Thus*, or *Olibanum sylvestre*), and in large irregular lumps or compressed cakes. When recent the colour should be white, or only inclining to yellow, subdiaphanous, soft, tenacious and glutinous: by the action of time it becomes hard, and even friable, the colour having deepened into an orange hue. By the heat of the hand it softens, and by a higher temperature liquifies. It possesses a turpentine-like odour and taste. It is insoluble in water, but completely soluble in alcohol with the aid of heat. It consists of two kinds of resin mixed with oil of turpentine. By melting it in water, and straining it through strong cloths, it is deprived of much of its oil, when it is termed Pix Arida, or Burgundy Pitch. For the genuine Thus, or Frankincense of the ancients, see Boswellia; also Olibanum, as the substances distinguished by this name (derived from the Arabic Looban) were of different kinds, and procured probably from Africa and Arabia, as well as from India.—*Eng. Cyc.* The substance called Koondricum by the Tamools is very common in the Indian bazars, and is used as an incense in religious ceremonies, equally by the Hindoos and Portuguese Christians, being, though not quite of so grateful an odour, cheaper than Benzoin. It is supposed by the Mahometan Doctors, to be a species of Olibanum and they give the name of Coondoor to both; but it is very unlike Olibanum in its appearance; being always seen in pretty large, agglutinated masses, composed of light brown and yellowish tears, and having a strange stony kind of hardness when pressed betwist the teeth, whereas the Olibanum is in separate small roundish balls, or large grains which do not give the same sensation on being chewed, nay even stick to the teeth. The Koondricum is generally brought to this country from Madagascar from the coast of Borneo, and also from Pedir on the Island of Sumatra. The Vytians prescribe it when mixed with ghee in cases of Vullay (Gonorrhœa) they use it also in a certain bowel affection called Ritta Kaddapoo, which corresponds with our Flux when accompanied with blood.—*Ain's Mat. Med. p.* 16. The Frankincense of India, is the produce of a species of Boswellia.

(3968) FRAXINUS. The wax insect tree, of China, says Mr. Fortune, is a species of ash (fraxinus). It grows abundantly on the banks of ponds and canals in the province of Chekiang; and a small quantity of wax is also produced in this province. I was indebted to Mr. McCartee of Ningpo, for some beautiful specimens of the fresh insect upon the branches of this tree. This insect has been named *Coccus pela* by Mr. Westwood. When fully developed on the trees it has a most remarkable appearance, they seem as if covered with flakes of snow. The wax is an article of great value in Chinese commerce, and a small portion is exported.—*Fortune's Residence, page* 140.

(3969) FRAXINUS, FLORIFERA, *Syn.* Ornus florifera, Flowering ash Tree, mountains of the South of France. To these two species rotundifolia and F. florifera and probably also to other species, we owe the manna of the European druggists.—*O'Shaughnessy, p.* 434.

(3970) FRAXINUS ROTUNDIFOLIA. *Syn.* Ornus rotundifolia, round leaved manna ash tree, a native of Calabria and Sicily.—*O'Shaughnessy, paye* 434.

(3971) FRENCH BEANS from the Government Gardens Ootacamund. It is well known that the French Beans form the principal food of the French peasants and soldiers. These beans contain more nutritive matter than any other known vegetable product, and on that account are most desirable for the supply of troops. In France they are sold at from 2½d to 5d per lb. according to colour, the white kinds bringing the highest price. They could be produced on the Neilgherries, if grown in large quantities at about half the abovementioned price. Exhibited in order to call attention to this fact.—*Mr. McIvor.*

(3972) FRENCH POLISH consists of a resin or a gum-resin dissolved in spirit, and used for polishing flat surfaces. For this purpose it is made more fluid than the hardwood lacker, used in polishing turned surfaces, in order that it may spread easily and dry less rapidly; because the friction being derived entirely from the motion of the hand, more time is required than in polishing turned works. The recipes for making French polish are innumerable. Indeed, it is seldom

prepared in the same manner by two different makers. Some prefer it very thin, others tolerably thick; some, of one colour; some, of another; while others make it colourless or nearly so. The simplest method is to dissolve 1½ lb. of shell-lac in 1 gallon of spirits of wine without heat. Copal, sandarac, mastic, and gum arabic are sometimes used in various proportions, according to the fancy of the preparer. Some recommend 12 ounces of shell-lac, 6 ounces of gum arabic, and 8 ounces of copal, to 1 gallon of spirits of wine. A dark-coloured polish is prepared with 1 lb. of shell-lac, ½ lb. of benzoin, and 1 gallon of spirits; or 1½ lb. shell-lac, 4 ounces of guaiacum, and 1 gallon of spirits. Dragon's blood may also be used to give the required tint. The hardest and most durable polish is made with shell-lac and spirits without any other ingredients. It is usual to make the varnish thicker than is required for use, and to thin it down with spirit when being used. A tough polish is said to be produced from 1½ lb. of shell-lac, 4 oz. of seed-lac, 4 oz. of sandarac, and 2 oz. of mastic to the gallon of spirit; or 2 lbs. of shell-lac and 4 oz. of thus to the gallon. A light-coloured varnish may be made with bleached or white lac; but this darkens by exposure to light.—*Tomlinson.*

(3973) FRITILLARIA. Liliaceæ. *Fritillaria Imperialis.* These are bulbous rooted plants with very showy flowers, growing well in any light garden soil, the colours are various. They are increased by off-sets.

(3974) FROGS are eaten in China, by all classes. They are caught in a curious manner by tying a young and tender jumper, just emerged from tadpole life by the waist to a fish-line, and lobling him up and down in the grass and grain of a rice field, where the old croakers are wont to harbour. As soon as one sees the young frog, sprawling and squirming in the grass, he makes a plunge at him and swallows him whole, whereupon he is immediately conveyed to the frog-fisher's basket, losing his life, liberty, and lunch together, for the bait is rescued from his maw, and used again as long as life lasts.—*William's. Middle Kingdom. Vol. 2. p.* 48.—Frogs says Fortune, are in great demand in all the Chinese towns, both in the north and south, wherever I have been, and they were very abundant in Nantsin. They abound in shallow lakes and rice fields, and many of them are very beautifully coloured, and look as if they had been painted by the hand of a first rate artist. The vendors of these animals skin them in the streets in the most unmerciful and apparently cruel way which I have already described.—*A. Res. among the Chin. p.* 343. Frogs seemed much in demand. They are brought to market in tubs and baskets, and the vender employs himself in skinning them as he sits making sales. He is extremely expert at this part of his business. He takes up the frog in his left hand, and with a knife which he holds in his right chops off the fore part of its head. The skin is then drawn back over the body and down to the feet, which are chopped off and thrown away. The poor frog, still alive, but headless, skinless, and without feet, is then thrown into another tub, and the operation is repeated on the rest in the same way. Every now and then the artist lays down his knife, and takes up his scales to weigh these animals for his customers and make his sales. Everything in this civilised country whether it be gold or silver, geese or frogs, is sold by weight.—*Fortune's Residence in China, p.* 45.

(3975) FRUITS. In few natural products is India more prolific than in its fruits. The pine-apple, mango, mangosteen, jambo, tamarind, &c., are amongst the best known, besides an infinite variety of smaller fruits partaken by the natives, either dried or in their curries. To the north, and in the hill-districts, peaches, grapes, figs, &c., are both abundant and of good quality. In the south and central parts of Hindustan the fruits and vegetables in general use amongst the people are melons, gourds, cucumbers, water-melons, plantains, guavas, jujubes, custard-apples, and figs. In some of the hill-districts the wild raspberry and a species of gooseberry are found in great abundance and of good quality.

Fruits and seeds dried and used as Food in India.

Almonds, both *sweet* and *bitter*,	N. W, India and Bombay.
Apricots, (Khobanee,)	N.W. India, from Kunawur and Caubul.
Plums, (Aloo Bokhara)	N. W. India, from Caubul.
Raisins, (Monukka Kishmis Bedana,)	N. W. India, from Istaulik, &c.
Figs, (Unjeer)	N. W. India, from Caubul.
Dates, (Choohara,)	Bombay, from Persian Gulf.
Pistacio Nuts, (Pista)	N. W. India, from Caubul, &c.
Pine Nuts, (Neoza Chilghozal,)	Do. do. do.
Walnuts, (Ukrot,)	Do. and Himalayas and Cashmere.
Cocoanuts, dried Kernels, (Copra,)	Bombay, from Malabar Coast.

Dr. Faulkner observes, as, indeed, Dr. Royle has also observed, that large quantities of Apples, Pears, and other fruits are annually imported into all the North-Western parts of Hindoostan from Cabool and Cashmere. It admits of little doubt that these fruits could be cultivated to perfection in the Himalayan mountains, at altitudes of from six thousand to seven thousand feet above the sea, and an advantageous traffic in them established in the hills.—*Royle, Pro. Res.*

Wild Fruits of Pegu.—These are more numerous than the cultivated fruits, and may be considered under two heads, namely, green fruits, employed rather as esculent vegetables, and sub-acid fruits. Of the first, the fruit of the

Dillenia speciosa. Theet-foe.
Xanthochymus pictorius. Ny-an-gyee.

Sandoricum indicum Yan-sa.
Randia oliginosa. Wambula.
Mangifera attenuata. Kyain.
Soneratia apetala. Than.
Ficus macrophylla, F. glomerata, F. lanceolaria. Oung.
Calamus, Borassus, Cocus.

are used as an addition to curries. The sub-acid wild fruits, eaten only in their ripe state, are the berry of *Flacourtia cataphracta*, with much of the appearance and flavor of a plum.

Pierardia Sapoa, which resembles the *loquat*, but which grows in bunches like the *leechee*. It is equal to either of those fruits and might be greatly improved no doubt by cultivation. It is very plentiful in the Rangoon market from the end of April to the Middle of May. Kanuo-kuzza *Burmese.*
Garcinia Cowa, or wild mangosteen. Toun-thalai.
Spondias acuminata, or long Plum.
Spondias mangifera, the fruit is said to be pleasant, with a flavor like the mangoe. Kwai.
Ziyziphus jujuba. Hzee.
Mangifera oppositifolia, or wild mangoe Tan-thayet
Syzigium balsamicum, a purple berry, with a pleasant flavor.
Psidium pomiferum, a large yellow berry. Malaka.
Phyllanthus embelia, a large green berry, found in a dry state in the bazars. Hzee phoo.
Antidesma paniculata, small sour plum. Kyet-tha-hen.

To which may be added the albuminous seeds of *Morinda bracteata*, the bean of *Inga doneean*, the acorn of *Castanea indica*, and the seed of the *Jack*, which when roasted are articles of food; while an infusion of the fruit of *Elaeodendron orientale* is drunk by the Burmese as tea.—*McClelland.*

Table Fruits.—There is a great variety of fruits indigenous and exotic in the Tenasserim Territories, and to a native, who while a child eats a raw sweet potatœ with as must zest as a European would an apple, they are no doubt considered unsurpassable. The ancient Celts eat acorns, and the modern Californians still use acorn bread, and the Burmese and Karens eat fruits which are but little superior to an acorn. Some however, are thought to be delicious and are held in high repute; but in general they are much inferior to the fruits of temperate climates.—*Mason.* The only trees to the cultivation of which the Chinese pay any attention, are the fruit-bearing kinds; and in some places there are very fair orchards containing the Mango, Leechee, Longan; Wangpee, Orange, Citrons, and Pumelows. *Fortune's Wanderings, page* 22. There are, however, two fruits cultivated in Chusan which are of considerable excellence, the one is called *yangmai*: it is a scarlet fruit, not unlike an arbutus or strawberry, but having a stone like a plum in the centre, the other is the Kum-quat, a small species of Citrus, about the size of an oval gooseberry, with a sweet rind and sharp acid pulp. This fruit is well known in a preserved state by those who have any intercourse with Canton, and a small quantity is generally sent to England as presents every year. Preserved in sugar, according to the Chinese method, it is excellent. Groves of the kum-quat are common on all the hill-sides of Chusan. The bush grows from three to six feet high, and when covered with its orange-colored fruit, is a very pretty object.—*Fortune's Wanderings, page* 69.

The shaddock, plantain, and persimmon, are common, and several varieties are enumerated of each; the plantain is eaten raw and cooked, and forms no inconsiderable item in the subsistence of the poor. The pomegranate, carambola or tree gooseberry, mango, custard-apple, pine-apple, rose-apple breadfruit, fig, guava, and olive, some of them as good and others inferior to what are found in other contries, increase the list. The *whampe*, *lichi*, *lungan*, or "dragon's eyes," and *loquat*, are the native names of four indigenous fruits at Canton. The first resembles a grape in size. and a gooseberry in taste; the loquat (*Eriobotrya*) is a kind of medlar. The lichi looks like a stawberry in size and shape; the tough, rough red skin incloses a sweet watery pulp of a whitish color surrounding a hard seed. Grapes are plenty and tolerably good but the Chinese have not yet ascertained that they contain wine; at least none is made. —*William's Middle Kingdom, Vol* II, *page* 45.

(3976) FUCUS. Agar-agar is the Malay name for a species of marine alga, the Fucus sacchari-nus of botanists; growing on the rocky shores of many of the Malayan islands, and forming a considerable article of export to China by junks. It is esculent when boiled to a jelly, and is also used by the Chinese as a vegetable glue.—*Crawfurd Dic: page* 6.

(3977) FUCHSIA. ONAGRACEÆ. *Fuchsia hybrida.*—This is a beautiful genus of plants, and can only be cultivated during the rains and cold season, as they die off with every care taken, during the hot weather, they grow freely from slips, procurable at the Neilgherries, and may be sent to a great distance if packed either in a tin case, or bamboo, surrounded with damp moss, the soil in which they strike best is a light sandy loam, the slips until they have thrown out strong shoots, and leaves must never be exposed to the sun, and even then only early in the morning.—*Riddell.* It is much to be regretted that this splendid family of plants will not succeed on the plains.—*Jaffrey.*

(3978) FULLER'S EARTH.

Terre a foulon, FR. | Walkererde. GER.

A soft, dull, greasy kind of clay, usually of a greenish-brown colour. It is used in the fulling of cloth, from its property of absorbing oil and greasy matter. It is found in various parts of the South of England. Two kinds are distinguished; *yellow earth*, the best, employed for the finer cloths of Wiltshire and Gloucestershire; and *blue earth*, principally used in fulling coarser cloths in Yorkshire.—*Waterston. Faulkner.*

(3979) FUMARIA from the Latin *fumus*, smoke, in allusion to the unpleasant smell which it exhales; the French, with the same meaning,

call it Fumeterre, and hence our English word Fumitory), a genus of plants the type of the natural order *Fumariaceæ*. It has 4 petals, the upper one spurred at the base, 2 sepals, diadelphous stamens, fruit indehiscent and 1-seeded. There are about 12 species of *Fumaria*, which are smooth slender herbs, with small racemose white or purplish flowers.—*Eng. Cyc.*

(3980) FUMARIA OFFICINALIS, OR FUMITORY, is used as a bitter tonic, and diaphoretic in Europe. Ainslie under the head F. officinalis, gives the following synonymes—*Shatra*, Pers. and Duk.—*Pit-papra*, Hind. *Bucklutul-melic*, Arab. He states he found the dried plant in a druggist's shop in Trichinopoly, and that the Hakeems consider it diuretic. Among European practitioners, it was long regarded as a valuable tonic and alterative.—*O'Shaughnessy, page* 184.

(3981) FUMARIA PARVIFLORA has ovate sepals as broad as the corolla and about two-thirds shorter. It greatly resembles *F. officinalis*, but is smaller in all its parts. The flowers are of a pale-red colour. It is found in Kent, and is also very common in the East Indies, where it is used as a medicine. The leaves have a bitter taste, and Dr. Whitlaw Ainslie mentions it in his 'Materia Medica of Hindostan.' The Mohammedans employ it as a diuretic, and in maniacal cases. The plants of this order have watery juice, are common in the Himalayas from Nepal to Cashmere, and contain a bitter principle.—*Eng. Cyc. O'Shaughnessy.* Fumaria parviflora, (PITPARA), is considered to be identical with the χαπνος of the Greeks; it is much used in the Upper Provinces, mixed with black pepper, in the treatment of intermittent fevers.—*O'Sh.*

(3982) FUMITORY.

Bucklut ul-melic. ARAB.	Pit-papra, GUZ. & HIND,
Shahtra, DUK,	Shahtra, PERS.
Fumeterre, FR.	

This plant is a tonic, and is supposed to be useful in leprous affections. It is a common weed in English corn-fields; and like many other medicines, has had its day of good repute. It is procurable in most Indian bazars.

(3983) FUNGI.

Kana kuchoo, HIND.

Under this name botanists comprehend not only the various races of mushrooms, toadstools, and similar productions, but a large number of microscopic plants forming the appearances called mouldiness, mildew, smut, rush, brand, dry-rot, &c. Notice has been occasionally taken of these plants under their respective heads; in this place some general account will be given of them as a large natural order. The common field mushroom, the morel and truffle, are the species of this order most usually eaten. But several poisonous fungi so closely resemble the common mushroom, that the utmost caution is necessary in their use. No test whatever, whether botanical or chemical, can be relied on to distinguish the dangerous from the wholesome kinds. Special cultivation is the only sure mode of procuring the mushroom of invariably good quality—*O'Shaughnessy, page* 673. Dr. Hooker says that in conclusion, I shall beg to add a few words on the Fungi of the Himalayas, so far as they have at present been investigated. As regards these there is a marked difference, as might be anticipated from the nature of the climates between those parts of Tibet investigated by Dr. Thomson, and the more southern regions. The fungi found by Dr. Thomson were but few in number, and for the most part of very ordinary forms, differing but little from the produce of a European wood. Some, however, grow to a very large size, as, for instance, *Polyporas fomentarius*, on poplars near Iskardo, exceeding in dimensions anything which this species exhibits in Europe. A very fine *Æcidium* also infests the fir trees (*Abies Smithiana*), a figure of which has been given in the "Gardeners' Chronicle," 1852, p. 627, under the name of *Æcidium Thomsoni*. This is allied to the Hexenbesen of the German forests, but is a finer species and quite distinct. *Polyporus oblectans, Geaster limbatus, Geaster mammosus, Erysiphe taurica*, a *Boletus* infested with *Sepedonium mycophilum, Scleroderma verrucosum*, an *Æcidium*, and a *Uromyces*, both on *Mulgedium Tataricum*, about half-a-dozen Agarics, one at an altitude of 16,000 feet above the Nubra river, a *Lycoperdon*, and *Morchella semilibera*, which is eaten in Kashmir, and exported when dry to the plains of India, make up the list of fungi.—*Hooker's Himalay. Journal, Vol.* II. *page* 381. The region of Sikkim is perhaps the most productive in fleshy fungi of any in the world, both as regards numbers and species, and Eastern Nepal and Khasia yield also an abundant harvest. The forms are for the most part European, though the species are scarcely ever quite identical. The dimensions of many are truly gigantic, and many species afford abundant food to the natives. Mixed with European forms a few more decidedly tropical occur, and amongst those of East Nepal is a *Lentinus* which has the curious property of staining every thing which touches it of a deep rhubarb yellow, and is not exceeded in magnificence by any tropical species. The *Polypori* are often identical with those of Java, Ceylon, and the Philippine Isles, and the curious *Trichocoma paradoxum* which was first found by Junghuhn in Java, and very recently by Dr. Harvey in Ceylon, occurs abundantly on the decayed trunks of laurels, as it does in South Carolina. The curious genus Mitremyces also is scattered here and there, though not under the American form, but that which occurs in Java. Though *Hymenomycetes* are so abundant, the

Discomycetes and *Ascomycetes* are comparatively rare, and very few species indeed of *Sphæria* were gathered. One curious matter is, that amongst the very extensive collection which have been made there is scarcely a single new genus. The species moreover in Sikkim are quite different, except in the case of some more or less cosmopolite species from those of Eastern Nepal and Khasia : scarcely a single *Lactarius* or *Cortinarius* for instance occurs in Sikkim, though there are several in Khasia. The genus *Boletus* through the whole district assumes the most magnificent forms, which are generally very different from anything in Europe.—*Hooker Him. Jour. Vol.* II. *page* 382.

(3984) FURNITURE. The natives of India have been long celebrated for the great patience and fidelity with which they imitate the most elaborate details either of art or manufacture, but they are generally deficient in design, and the articles exhibited prove that much may still be done to infuse artistic taste and boldness of execution when the better principles of art are brought to bear upon this branch of industry. The following is a Tabular View of the woods used for furniture in Madras contributed by Dr. Cleghorn.

Common Furniture.	Carved and Ornamental Furniture.
1 Chitagong wood.	1 Ebony.
2 Teak wood.	2 Blackwood, *or* East Indian Rosewood.
3 Toon.	3 Satin wood.
4 Jack.	5 Kiaboca wood.

1. *The Chittagong wood* (*Chickrassia tabularis*) is more used at Madras in the making of furniture than any other wood. It is light, cheap and durable.

2. *The Teak* (*Tectonia grandis*) is probably the most durable of all timbers, it is very hard, and very heavy. It is extensively used for bullock trunks and for house and camp furniture, for which it is well adapted, as it does not split.

3. *The Toon* (*Cedrela toona*) resembles its congeners, chittagong wood and mahogany, and is very much used for furniture all over the Peninsula.

4. *The Jackwood* (*Artocarpus integrifolia*) is an excellent timber, at first yellow, but afterwards brown, when made into tables and well kept it attains a polish, little inferior to mahogany. In England it is used as well as satin wood for making backs of hair brushes, &c.

1. *Black Ebony* (*Diospyros melanoxylon*). This well known and much admired wood, lignum nigrum, non variegatum ? is very hard, heavy, and susceptible of a high polish. It is seldom obtained of great size.

2. *East Indian Blackwood or Rosewood*, is an excellent heavy wood, suited for the best furniture. It can be procured in large quantities, and of considerable size, the wood contains much oil. In large panels it is liable to split.

3. *Satin wood* (*Swietenia chloroxylon*) is hard in its character and when polished it is very beautiful and has a satiny lustre, it is much used for picture frames, rivalling the birds eye maple of America. It is occasionally used by cabinet makers for general furniture, but it is liable to split.

4. *Sandal wood* (*Santalum album*) is found in abundance in Mysore and Canara ; it is chiefly remarkable for its agreeable fragrance, which is a preservative against insects. It is much used in making work boxes, walking sticks, penholders, and others small articles of fine ornament but cannot be procured of a large size.

5. *Kiaboca wood* (*Pterospermum indicum.*) Is imported from Singapore It is beautifully mottled, of different tints, evidently produced by excrescences from the tree. The wood is chiefly used for inlaying or for making desks, snuff boxes, puzzles, &c.—*M. E. of* 1855.

(3985) FURS. Are the skins of different animals, covered, for the most part with thick fine hair ; the inner side being converted by a peculiar curing process, into a sort of leather. Furs, previously to their undergoing this process, are termed *Peltry*. The fur of the flying squirrel (Pteromys petaurista) is of such a very fine description, that we doubt not that it would excite much interest at home.

(3986) FUSTIC.

Gheelhout, Dut.	Legno giallo de Brasilio, It.
Bois jaune de Bresil, Fr.	Palo del Braasilamrillo, Sp.
Gelbholz, Fustick, Ger.	

A dye-wood, the produce of a large tree, (*Morus tinctoria*), Maclura tinctoria, a native of the tropical parts of America, and the West Indies. The wood is of a sulphur colour, and the yellow dye which it affords, though extremely durable when in combination with an aluminous base, yet being dull and muddy, is chiefly employed in compound colours. Fustic is obtained from Maclura tinctoria, or Broussonetia tinctoria, Kunth, a large and handsome evergreen tree, growing in South America and the West Indies. The wood is extensively used as an ingredient in the dyeing of yellow, and is largely imported for that purpose. Fustic, dye-stuff, the *bois-jaune* of the French, is the wood of the *Morus tinctoria*, a large tree growing in Brazil, Jamaica, and most of the West Indian islands. A concentrated decoction of fustic, deposits, on cooling, a yellow crystalline matter named *morine*. 1 part of fustic boiled in 10 of water for 15 minutes, gives a yellow decoction, which gradually deposits morine. The decoction is inodorous, slightly astringent and bitter, and precipitates gelatine. With protochloride of tin, and with alum, it gives yellow precipitates ; orange-coloured with acetate of lead ; yellow-brown with

acetate of copper, and dark olive with persulphate of iron. With sulphuric acid, it gives an orange-coloured precipitate, soluble in excess of the acid. It is reddened by nitric acid, and rendered paler by oxalic and by acetic acid. The yellow of fustic is said to produce several greens with indigo, with which it unites well. By the new tariff, fustic is admitted into the United Kingdom free of duty.—*Tomlinson.* The name appears to be derived from Fustet, the French name of a yellow dye-wood, the produce of Venetian sumach. A wood similar in colour and uses, but larger in size, having been subsequently imported from the New World, had the same name applied to it with the addition of Old, while the other, being smaller, is called Young Fustic; but these, so far from being the produce of the same tree at different ages, do not even belong to the same genus. Young Fustic, or as it is sometimes called Zante Fustic, is the produce of *Rhus cotinus* (*Anacardiaceæ*), a native of Italy, the South of France, and of Greece; much of it is exported from Patras in the Morea; and it also extends into Asia. It is supposed to be the *Cotinus* of Pliny, being still called Scotinoo near Valcimara. in the Apennines, where it is cultivated on account of its uses in tanning. The root and the wood of this shrub are both imported, deprived of their bark, and employed for dyeing a yellow colour approaching to orange, upon wool or cottons, prepared either with alum or the nitro-muriate of tin with the addition of tartar. The colour is a beautiful bright yellow, and permanent when proper mordants are employed. Only small quantities of this kind of Fustic are imported. Dr. Sibthorp was of opinion that *Rhamnus infectoria*, or *R. oleoides*, of which the berries are called French and Persian Berries, yielded the Fustic of commerce, and informs us that its yellow wood is called by the Greeks 'chrysoxylon.' He also thought that it was the *Lycium* of Dioscorides, but this has been shown by Dr. Royle to be a species of *Berberis*, of which genus all the species have yellow wood. Old Fustic, the 'Bois Jaune' of the French, is on the contrary the produce of a large tree, *Morus tinctoria*, the Dyer's Mulberry, of the natural family of *Urticaceæ*, a native of Tropical America and the West India Islands. The tree attains a height of 60 feet; the wood is yellow-coloured, hard, and strong, but easily splintered, and is imported in the form of large logs or blocks. The yellow, colour which it affords with an aluminous base, though durable, is not very bright. M. Chaptal discovered that glue, by precipitating its tannin enabled its decoctions to dye yellow almost as bright as those of weld and quercitron bark. The Fustic from Cuba is preferred, and fetches the highest price, varying from 8*l.* to 9*l.* 10*s.*, while that from Jamaica or Columbia varies from 5*l.* 10*s.* to 6*l.* 10*s.* per ton. The tree is figured by Sloane, and noticed by Maregrave and Piso. Browne describes it as a native of Jamaica, and deserving the attention of planters, as it is only propagated by birds, who are fond of its sweet roundish fruit. The several countries from which Fustic was imported, and the respective quantities received from each, were in 1836—

	Tons.
Italy and the Italian Islands ...	4
Ionian Islands	72
Morea and Greek Islands ...	18
British North American colonies	103
British West Indies	2053
United States of America ...	226
Mexico	172
Columbia	1913
Brazil	356
Total	4917

The quantity entered for home consumption in the United Kingdom was 1,731 tons in 1847, 1,653 in 1848, and 1,842 tons in 1849. Ninety one tons were shipped from Montego Bay, Jamaica, in the first six months of 1851. In 1850 the quantity imported into Liverpool was 9808 tons, of this 1771 tons were re-exported. (Simmonds, *The Commercial Products of the Vegetable Kingdom*, *page* 485). Of Fustic England imports from 1,500 to 2,000 tons annually. We derive our supplies from Brazil, Tampico, Puerto Cabello, Cuba, and Jamaica. The best is obtained from Cuba, for, while the common white fustic from Jamaica and the Spanish Main fetches only £5 10*s.* to 6£ 10*s.* the ton, that of Cuba realizes from £8 to £9 10s. the ton. *Simmonds, page* 446.

(3988) GAB. Fruits of Dyospyros embryopteris, the size of a small orange; deep green, with a rusty dust; strongly astringent and mucilaginous.—*Irvine, Med. Top.*

(3989) GÆRTNERA RACEMOSA, Branching Gærtnera. Maltilata, Hind.

A fine specimen runs over some trees in the Dowlet bagh at Ajmeer. This is a fine and

fragrant flowered creeper, and very hardy.—*Gen. Med. Top. p.* 192. Wight in Icones, gives also G. Konigii.

(3990) GAILLARDIA PICTA. These flowering plants are chiefly from North America, grown in any garden soil, and may be increased by dividing the roots, common everywhere, the scent of some of the species is unpleasant.—*Riddell.*

(3991) GAJUBA. Leaves and triangular stalks of a small succulent plant, brought from Bombay, heating, and used as a purge.—*Gen. Med. Top. p.* 135.

(3992) GAJUR. Daucus Carota :—Carrot.

(3993) GALANGAL.

Colenjun, Guz. Hind. | Galgant, Ger,
Galanga, Fr. |

A brown tuberose root, with a faint aromatic smell, and pungent taste, like a mixture of pepper and ginger. Galanga, or Galangal, is usually supposed to have been introduced by the Arabs, but it was previously mentioned by Ætius. The Arabs call it Kholingan, which appears to be derived from the Hindoo Koolinjan, or Sanscrit Koolunjuna, indicating the country whence they derived the root, as well as the people from whom they obtained their information respecting its uses. The plant which yielded this root was long unknown, and it was supposed to be that of a Pepper, of an Iris, of *Acorus Calamus*, or to be the *Acorus* of the ancients. *Kæmpferia Galanga* was so called from its aromatic roots being supposed to be the true *Galangal*. The tubers of *Cyperus longus* were sometimes substituted, and called English Galangal. Two kinds, the large and the small galangal, are described; these are usually considered to be derived from the same plant at different stages of its growth, but Dr. Ainslie, in his 'Materia Indica,' insists upon the greater value of the lesser, as this is warmer and more fragrant, and therefore highly prized in India. It is a native of China, and the plant producing it is unknown. Dr. Ainslie does not prove that it is the *Galangal minor* of Europe. The Greater Galangal has long been known to be the produce of a Scitamineous plant, the *Galanga major* of Rumphius ('Herb. Amb.' 5. t. 63), which is the *Alpinia galanga* of Wildenow, and a native of China and the Malayan Archipelago. It is fully described by Dr. Roxburgh, in his 'Flora Indica,' vol. i. p. 28, ed. Wall. The roots, perennial and tuberous, like those of the ginger, were ascertained by Sir Joseph Banks and Dr. Comb to be identical with the *Galanga major* of the shops. This is cylindrical, often forked, thick as the thumb, reddish-brown externally, marked with whitish circular rings, internally lighter coloured, of an agreeable aromatic smell, and a hot spicy taste, like a mixture of pepper and ginger, with some bitterness. The stem is perennial, or at least more durable than those of herbaceous plants. When in flower, about 6 or 7 feet in length; its lower half invested by leafless sheaths. The leaves are two-ranked, lanceolar, from 12 to 24 inches long, and from 4 to 6 inches broad. Panical terminal, crowned with numerous branches, each supporting from two to five pale greenish-white and somewhat fragrant flowers in April and May in Calcutta, where the seeds ripen, though rarely in November. Several species of this genus have roots with somewhat similar properties. Thus *Alpinia alba* and *A. Chinensis* are much used by the Malays and Chinese; the former has hence been called *Galanga alba* of Kœnig; and the latter has an aromatic root with an acrid burning flavour. The fragrant root of *Alpinia nutans* is sometimes brought to England, according to Dr. Roxburgh, for *Galanga major*. Its leaves, when bruised, have a strong smell of cardamoms, and the *Cardamomum* plant is frequently placed in this genus, but has been described under Elettaria.—*Eng. Cyc. p.* 912. According to Dr. Honigberger (p. 278) the natives of Lahore are of opinion that the root of piper Betel (Pankejer) is what the Persians call Koolian, which is the Indian Galanga. Galanga root is a good deal used in China, and forms an article of commerce, fetching in the London market from 12s. to 16s. per cwt. in bond. Its taste is peppery and aromatic. Externally the color of the root-stocks is reddish brown, internally pale reddish white. 1,286 cwt. of Galangal root, valued at 2,880 dollars, was exported from Canton in 1850.—*Simmond's Comml. Product, p.* 418.

(3994) GALBANUM.

Barzud; Arab. | Galbanum; Lat.
Galbanum; Fr. | Beerzud Pers.
Mutterharz; Ger. | Khelbenah, Hebrew,
Bireeja; Hind. | χαλβανη Greek.
Galbano; It. |

Galbanum occurs in agglutinated plastic masses, mixed with seeds and fragments of leaves, of greasy aspect, adhering strongly to the fingers, by which it is quickly softened; white, brittle tears occur in the mass resembling pine resin; in odour this drug is analogous to ammoniacum; its taste is hot, acrid, and bitter. The essential oil is colourless, but becomes yellow by keeping it distilled from water; of a deep blue if distilled by direct heat. Water dissolves about a fourth of this drug, but deposits the greater part again; weak alcohol dissolves it altogether. Its properties are the same in kind as those of asafœtida, but it is much less powerful.—*O'Shaughnessy, page* 367. Though the drug called by this name is one of those which have been the longest known, the plant which yields it still remains undetermined, though it is stated by old writers to be a native of Syria. The Greek name Chalbane (χαλβάνη) is evidently the same as the Hebrew Chelbenah, by which the same substance is supposed to be al-

luded to in the book of Exodus. Arabian authors describe it under the name Barzud. The Persians call it Birzud, and give Birceja as its Hindoo synonym. That the same substance is intended, is evident from Khulyan and Metonyon as stated by Dr. Royle ('Illustr. Himal. Bot.,' p. 23), being given as its Greek synonyms, which are evident corruptions of Chalbane and Metopion, the names of this substance in Dioscorides. The plant yielding this substance is called Kinneh and Nafeel by Arabian and Persian authors, by whom it is described as being joined, thorny, and fragrant. Under the first name it is noticed in the original of Avicenna, but omitted in the Latin translation. D'Herbelot ('Bibl. Orient.') however states, that the plant yielding Galbanum is called Ghiarkust in Persia. These names are interesting only as showing that both the plant and gum-resin appear to have been familiarly known to both Arabians and Persians, and that therefore the former is probably a native of these countries, though usually stated to be only a native of Syria. But if so, it could hardly have escaped the notice of the numerous travellers who have visited that country.—*Eng. Cyc.* According to Dr. Royle, Galbanum is supposed to be the same substance as the *Chelbenah* of Scripture (v. Cycl. of Biblical Lit.), as this word is very similar to the χαλβανη of the Greeks, which was known to Hippocrates, and is described by Dioscorides, who gives μετωπιον as an additional name. Theophrastus had long previously stated that it was the produce of a *Panax*, Dioscorides of a *Ferula* of Syria. But this word had a wide geographical signification in ancient times. Arabic and Persian authors seem to have been well acquainted with the plant, as they give *kinneh* and *nafeel* as its names, and *barzud* as that of the gum-resin. D'Herbelot states that this is the same as the *pirzed* of the Persians, who call the plant yielding it *giarkhust*. But whatever the plant may be, it is unknown to botanists. Lobel attempted to ascertain it by sowing some of the seeds which he found attached to Galbanum, and obtained *Ferula Ferulago*, a native of North Africa and of Asia Minor, but which is not known to yield Galbanum; while *Bubon galbaniferum*, which is sometimes adduced, is a native of the Cape of Good Hope. The late Professor Don having found some seeds sticking to Galbanum, named the plant yielding them, though yet unknown, *Galbanum officinale*, belonging to the tribe *Silerinæ*, which is admitted in the London Pharmacopœia. But these fruits may, or not, be those of the Galbanum plant. Dr. Lindley has in consequence suggested another plant, of which he received the fruits from Sir John Macneil. This grows at Durrood, near Nishapore, in Khorassan, and yields a gum-resin of which a specimen seen by Dr. Pereira did not correspond with any known gum resin. Dr Royle has several such in his collection. Dr. Lindley has named the plant which is admitted into the Edinburgh Pharmacopœia. *Opoidia galbanifera*, tribe Smyrneæ. But there is equal uncertainty about all.—*Royle.* One plant, often described as yielding this long-known gum-resin, is *Bubon galbanum*, a native of the Cape of Good Hope, which Hermann describes as yielding spontaneously, by incision, a gummy, resinous juice, similar to Galbanum; but Mr. Don has observed that this plant possesses neither the smell nor the taste of Galbanum, but in these particulars agrees better with fennel; and its fruit has no resemblance whatever to that found in the gum. The fruit, commonly called seed, was early ascertained by Lobel to be that of an Umbelliferous Plant, broad and foliaceous, which he picked out of *Galbanum*, and having sowed, obtained a plant, which he has figured under the name of *Ferula galbanifera*. This has been lost or become confounded with other species; but it is probable that it was the plant yielding Galbanum, as Mr. Don has recently obtained fruit in like manner, and something similar, which he has determined to be allied to the genus *Siler*, but differing in the absence of dorsal resiniferous canals, and the commissure being furnished with only two. The carpels are about 9 lines in length and 4 lines broad, flat internally and somewhat converse externally. As the plant is still unknown, it is well worthy the investigation of travellers in the East, who might otherwise suppose, from the name, assigned from the seed, having been adopted in the 'London Pharmacopœia,' that the plant was as well known as its product.—*Eng. Cyc.* Galbanum is imported from India and the Levant, having probably been brought down the Persian Gulf. It is usually met with in masses of a brownish-yellow colour more or less translucent and shining, sometimes in small tears which are of a paler or even yellowish colour.—*Royle.* Three sorts of Galbanum are distinguished:—1. Galbanum in grains or tears; 2. Galbanum in masses; and 3. Persian Galbanum. The two former come from Africa, especially Æthiopia: the third sort from Persia. Galbanum in tears is most likely the spontaneous exudation from the plant; and that in masses, obtained by incisions. The first sort occurs in irregular generally oblong grains, mostly distinct, but sometimes agglutinated together, about the size of a lentil or small pea, of a colour verging from whitish into yellowish-brown, more or less diaphanous, opaque, or shining with a resinous lustre. The odour is strongly balsamic, and disagreeable. The taste is resinous, sharp, bitter, and disagreeable. Specific gravity, 1·212. It is partially soluble in alcohol, and the solution, as well as the strong white smoke which is evolved when Galbanum is melted in a platinum spoon, reddens litmus paper. It consists chiefly of resin, gum, volatile oil, and a trace of malic acid. Galbanum in masses consists of irregular

pieces of a yellowish or dark brown colour; the odour is stronger than that of the preceding kind, which, in its general characters, it much resembles, except that it can be procured only during the low temperature of winter. Geiger says that when this variety is pure, it is not to be reckoned inferior to the former. Persian Galbanum, being very soft and tenacious, is sent in skins or chests. It often contains many fragments of plants. Galbanum, like other umbelliferous gum-resins, is anti-spasmodic, expectorant, and externally rubefacient. It is inferior in power to assafætida, but usually associated with it in pills and plasters.—*Engl. Cyc. Vol.* II. *pp.* 911 *and* 912. Dr. McClelland says that the plant affording this article is not well known, but Dr. Ainslie, as quoted by Dr. Royle, states its Hindustani name to be *Kinneh-ke-gond*, and the latter author observes that a gum resin, known in India under the name of *Kinneh-ke-gond*, is afforded by an exudation from the bark of *Odina wodier*. Now this tree constitutes probably a larger proportion of the forests both in the Prome and Tharawaddy districts than any other, and if found to afford *Galbanum*, might be rendered an important addition to the resources of the Province.—*McClelland.*

(3995) GALEDUPA ARBOREA AND GALEDUPA TETRAPETALA. Both of these yield an oil expressed from the seed, called in Bengal *Kurunga ka-tel*, which is used for burning, as well as medicinally for external use as an embrocation. In Tenasserim and Pegu, they are both very common trees, more especially in the Prome district. The seed is large and might be collected in any quantity.—*McClelland.* Wight in Icones, gives also G. elliptica and G. piscidia.

(3996) GALEDUPA INDICA, PONGARHEED.

Kurmeja or Kenja, HIND; Ganaga, TEL.

A pretty large timber tree, from forty to fifty feet high, common all over the Indian Peninsula, in Bengal &c. Leaves deciduous at the end of the cold season, and in about a month are succeeded by the new foliage. It flowers during the hot season, and the seed ripens toward the close of the year. The wood of this tree is light, white and firm; it serves for a variety of economical purposes. Branches stuck in the ground grow readily, grass and almost every thing else grows well under its shade. The seeds yield an useful oil.—*Rohde M.S.S.*

(3997) GALEDUPA TETRAPETALA. The flowers of this yield a fine red dye.—*McClelland.* See G. ARBOREA.

(3998) GALEGA ORIENTALIS, LEGUMINOSÆ. These are tolerably ornamental plants, and as they form a bush of small size they require room when planted out, the colours are mostly blue and white.—*Riddell.* Wight in Icones gives Galega Heyneana, 388; incana, 371; pentaphylla, 370; spinosa, 372.

(3999) GALENA, LEAD GLANCE, LEAD ORE, SULPHURET OF LEAD.

Plomb sulfure, FR. | Bleiglanz, GER.

The richest ore of lead, and from which that metal is chiefly obtained. As met with in commerce it is in heavy, shining, black, or bluish lead-coloured cubical masses; having a great resemblance to the sulphuret of Antimony (*Guz. Hind.* Soormah), for which it is very frequently mistaken. Localities, the lead hills in Lanarkshire, and other places.—*Faulkner.* At the Madras Exhibition of 1857 a rich ore of Argentiferous Galena was exhibited from Martaban by Dr. Brandis, granular, or in minute crystals, with silver passing through it in thready veins. This ore assayed by Dr. Scott contains about 80 per cent of silver lead. The quantity of silver was found to vary in the portion examined from 70 to 300 ounces in the ton of ore. It is impossible therefore to say what its commercial value may be, unless an average sample were obtained, but if the ore exists in any quantity and of the same quality as that examined, it is a most valuable one, and would be well worth working by Pattenson's mode for separating the silver, as the process proves remunerative where only 7 ounces of silver can be obtained from a ton of metal. This is probably the ore referred to by the Rev. Francis Mason, A. M. in his publication on the natural productions of Burmah. Where he says the limestone of the Provinces probably contains large quantities of lead. In the valley of the Salwen there is a rich vein of argentiferous galena, which is reported to appear on the surface. A specimen that Dr. Morton sent to England for analysis, was said to be a very valuable Mineral, and destined to make a fortune for some one. Professor Mitchell in the certificate that he furnished Dr. Morton of the analysis, says it contains Lead, Sulphur, Silver, Gold, (traces) Lime, Magnesia, Iron, Silica, and Carbonic Acid. It is a sulphuret of lead or galena. The quantity of lead and silver appears to be considerable, but there was not sufficient of the mineral to estimate either." The ore is seen in the limestone precisely as galena is found in the limestone of the Mississipi, one of the richest known deposits of lead in the world. In a small hand specimen from Martaban, the amount of silver was found to vary in different portions of it, the per centage of lead being about 75. In the first trial the silver was found to amount to about 70 ounces to the ton of ore; bnt in the second to not less than 300 ounces in the ton, or a little less than 1 per cent. Mr. O'Reiley states that the carbonate of lead exists near the head waters of the Hoimgdaram. Another locality from which Galena is exhibited is the Dhone Talook Kurnool, from which Galena in very large blocks has been obtained; one piece measured about 18 inches in diameter and

weighed upwards of 3 Cwt. This ore carefully tested by Dr. Scott some years ago, was then found to contain from 53 to 70 per cent. of lead but no silver; it was also tried at the Mint and yielded a large per centage of Lead. It has been used for some years at the Madras School of Arts for glazing Pottery and answers well for that purpose, though it is found to succeed better when reduced to the form of minium, and then ground with Felspar and an Alkali. It was brought to notice by Captain J. G. Russell and occurs in large quantities and in blocks of great size in the vicinity of Kurnool. Its history is interesting. It was discovered accidentally by the late ex-Nawaub of Kurnool, in digging a well. He was at the time making warlike preparations and considering the discovery of much importance he surrounded the excavation with a wall for the purpose of concealing it and placed a guard over the entrance of the enclosure. The pit has now however been choked up as since the Kurnool territory has fallen into the hands of our Government, no outlay has been sanctioned to ascertain the extent of the lode and whether it would be worth while working it. The galena has been used in large quantities in the School of Arts for glazing common pottery and has been found of excellent quality. The reexamination of the first specimen of the Kurnool ore proved it to contain upwards of 1 per cent of silver, or 574 ounces in the ton, the quantity of lead and silver together being only 45 per cent which was occasioned by there being a considerable quantity of gangue disseminated through the portion examined. Another specimen, given by Colonel Cotton and also said to be from Kurnool, was found to contain 175 oz. 3 dwts. in the ton. Dr. Scott observes, "some years ago I examined a specimen of the Kurnool Galena and found it to be free of silver; and I have been consequently, until the present time, under the impression that it contained none. But the examination of the specimens in this year's Exhibition reveals the fact that at least some portions are very rich in the precious metal and this accords with the recent researches of Malagah and Durochet who have found that when Sulphide of Silver is associated with the Sulphides of other metals, it is *always* unequally distributed. It would appear therefore from the above facts that it would be quite impossible to calculate, with any approach to accuracy, from the examination of any given specimen, what would be the average yield of silver in a silver lead mine, until it is actually worked for the separation of that metal, considering however that nearly one half of the silver now in circulation in Great Britain is recovered from silver lead ores similar to the above, and seeing that it is found to be advantageous to separate the precious metal where it exists to the extent of only 6 ounces in the ton, it becomes evident that these ores must be of great value, provided they can be found in sufficient quantity. From recent information obtained from Kurnool it would appear that the Galena there occurs abundantly in all probability; therefore it would prove to be highly remunerative to work this mine, both for the lead and silver contained in the ores. Among the metallic ores holding the promise of being marketable, are a rich ore of galena or sulphuret of lead from Jungumrazpillay in the vicinity of Cuddapah. This ore is rich in silver, and is worked by the Natives on this account, but all the lead is wasted and the silver is obtained by a tedious, clumsy, and expensive process. Mr. H. L. Pattinson's new process for separating the metals by careful, slow-cooling and crystalization, is applicable to this ore.—*M. E. of* 1857.

(4000) GALEOPITHECUS, a genus of *Mammalia*, having relations to the *Lemuridæ* and *Cheiroptera*. It is often formed into a family, and is then called *Pleuroptera* or *Galeopithecidæ*. They are commonly known by the name of Flying Lemurs, and are sometimes called Flying Cats and Flying Foxes. They are generally arranged under the order Carnassiers, and some authors place them in the division *Cheiroptera*; but they differ from the Bats inasmuch as the toes of their anterior extremities, which are all furnished with sharp claws, are not more elongated than those of the hind feet, so that the membrane which occupies the interval between the extremities to the sides of the tail can hardly operate in executing more than the functions of a parachute. The dental formula is as follows:—incisors, $\frac{4}{6}$; Canines, $\frac{2}{2}$; Molars, $\frac{6}{6}\frac{6}{6}=34$. This is the formula given by M. Lesson; but Cuvier, in his 'Regne Animal,' states that the canines are dentilated and short like the molars. He states that the two upper incisors are also dentilated and much separated from each other; and that the six lower ones are split into narrow strips like combs a structure peculiar to this genus. Three species have been recorded;—1. *Galeopithecus rufus*, Geoff., Audubon (*Lemur volans*, Linn.); 2. *Galeopithecus variegatus*, Cuv., Geoff.; 3. *Galeopithecus Ternatensis*, Geoff.: but the general opinion seems to have been that one only, the *Lemur volans* of Linnæus, had been satisfactorily made out. In October, 1838, some specimens of Flying Lemurs were upon the table at a meeting of the Zoological Society of London; and in reference to them Mr. Waterhouse pointed out certain characters which appeared to him to indicate the existence of two species in those specimens. He remarked that in systematic works three species of the genus *Galeopithecus* are described, founded upon differences of size and colour. As regards the latter character, he had never seen two specimens which precisely agreed; and with respect to size, the dimensions given of two out of the three species are, he observed, evidently taken from extremely young

animals. Mr. Waterhouse then proceeded to distinguish the two species on the table, and proposed for them the specific names of *Temminckii* and *Philippinensis*. The first and larger species measured about two feet in total length, and its skull was 2 inches 11½ lines in length. The anterior incisor of the upper jaw is broad, and divided by two notches into three distinct lobes; the next incisor on each side has its anterior and posterior margins notched; and the first molar (or the tooth which occupies the situation of the canine) has its posterior edge distinctly notched. This tooth is separated by a narrow space, anteriorly and posteriorly, from the second incisor in front and the second molar behind: the temporal ridges converge towards the occiput, near which however, he observed, they are separated usually by a space of about four lines. This is probably the *Galeopithecus volans* of authors; but the identity cannot be said to be certain.—The second species, *G. Philippinensis*, was described by Mr. Waterhouse as being usually about 20 inches in length, and its skull as measuring 2 inches 7 lines in length. He observed that this species may be distinguished from *G. Temminckii* by the proportionately larger ears and the greater length of the hands. The skull too he described as narrower in proportion to its length, the muzzle as broader and more obtuse, and the orbit as smaller. The temporal ridges, he observed, generally meet near the occiput, or are separated by a very narrow space. The anterior incisor of the upper jaw is narrow, and has but one notch; the next incisor on each side is considerably larger, longer, and stronger than in *G. Temminckii*, and differs moreover in having its edges even: the same remark applies to the first false molar. In this species the incisors and molars form a continuous series, each tooth being in contact with that which precedes and that which is behind it. But Mr. Waterhouse concluded by observing that the most important difference perhaps which exists between the two species in question consists in the much larger size of the molar teeth in the smaller skull, the five posterior molars occupying a space of ten lines in length, whereas in *G. Temminckii*, a much larger animal, the same teeth only occupy nine lines. Several minor points of distinction existed besides those here mentioned. ('Zool. Proc.,' 1839; and see further 'Zool. Trans.,' vol. ii. p. 335.)—*Eng. Cyc.*

(4001) GALEOPSIS (from γαλῆ, a weasel, and ὄψις, sight, aspect, the mouth of the corolla gaping like that of a weasel), a genus of Plants belonging to the natural order *Labiatæ* or *Lamiaceæ*. It has the anthers approaching in pairs, opposite cells bursting by two valves transversely; the upper lip of the corolla arched, and the lower lip 3-lobed, unequal, with two teeth on its upper side; a tubular 5-toothed calyx, with equal teeth, or the two upper ones longest. The nuts are rounded at the end. The species of this genus are annual divaricately branched erect herbs, and rarely decumbent at the base. The flowers are red or cream-coloured, or varied with both these colours. This genus may be easily recognised by the peculiar formation of its anthers, which differs from any other of the *Labiatæ*.

(4002) GALEOPSIS TETRAHIT, the Common Hemp-Nettle, has a hipsid stem, thickened below the joints, with oblong, ovate, acuminate, serrate leaves. The calyx has tubular teeth, and a tube nearly equal. The tube of the corolla is as long as the calyx, and has an ovate upper lip. It is a native of cultivated ground throughout Europe and middle Asia.—*Eng. Cyc.*

(4003) GALIACEÆ, *Stellates*, a natural order of Exogenous plants called *Stellatæ* by Linnæus, and merged in *Cinchonaceæ* by the School of Jussieu. It consists of herbaceous usually square-stemmed plants, with a scabrous surface, verticillate leaves, and monopetalous flowers, with an inferior didymous fruit inclosing a couple of seeds containing an embryo lying in a great quantity of horny albumen. Some yield a dyeing substance in their roots, as the various species of Madder, but the greater part are useless weeds. One common British species of *Galium*, namely, *G. Verum*, is astringent, and was formerly used by farmers to curdle milk.—*Eng. Cyc. Vol.* II. *page* 916.

(4004) GALLINÆ, Gallinaceous Birds, the fifth order of the class *Aves*, according to Linnæus, who thus characterises it:—Bill (a reaping sickle, 'Harpa colligens') convex; the upper mandible arched over the lower; nostrils overarched by a cartilaginous membrane. Feet formed for running; the toes rough below. Body sebaceous, muscular, delicate (purum). Food: grain collected on the earth and macerated in the crop (ingluvies). Nest artless and placed on the ground; eggs numerous; food pointed out to the young by their parent. Polygamous. Analogous to the order *Pecora* in the class *Mammalia*.

(4005) GALLINSECTA. [Coccidæ.]

(4006) GALLS.

Afis, Arab.	Gallæ, Lat.
Masaka, Cyng.	Mazu, Pers.
Mayphul, Duk.	Galhas, Port.
Noix de Galles, Ger.	Mayuphul, Sans.
Gallapfel, Ger.	Agallas, Sp.
Maya, Majoophal, Guz. Hind.	Machakai, Tam.
Galla, It.	Machikai, Tel.

Galls are the Gemmæ morbidæ, the diseased buds or excrescences, formed by Diplolepis (or Cynips) Gallæ Tinctorum, on Quercus infectoria, *Oliv.* The Gall-Oak. Galls were known to Hippocrates, and are described by Dioscorides (i. c. 147) under the name κηκις, which the Indo-Persian writers have converted into *fikees*. They are the *afees* of the Arabs, and well known

in India by the name of *majoo-phul*. Galls are imported into England from Smyrna, being produced in Asia Minor; also from Aleppo, the produce of the vicinity of Mosul in Kurdistan. They are also imported into England from Bombay (sometimes to the extent of 1000 cwt.) having been first imported there from the Persian Gulf. Mr. Wilkinson, of the house of Wilkinson and Jewsbury, informs us that formerly, when he paid much attention to this trade, he observed that whenever the prices were low at Smyrna, the Galls came from Bombay, and *vice versa*; but the supply was never abundant from both sources in the same year. They are imported into Bombay from Basra (Bussorah), which is not a great deal farther from Mosul than is Aleppo. They are therefore most probably the produce, like Aleppo Galls, of Kurdistan and of other Persian provinces. Dr. Falconer, when travelling in the Punjab, was informed that Galls were produced on the Balloot Oak, *Quercus Ballota*. —*Royle*. In the Tenasserim Provinces, Oak galls can always be obtained of the native druggists, but they are all imported, although there are several species of oak indigenous.—*Mason*. A kind of gall has lately been imported from China. Dr. Pereira describes it in the 'Pharmaceutical Journal' under the name of Woo-pei-tze; they are of very irregular shape, more bulky than the common galls, and hollow, the external shell being only about $\frac{1}{32}$ of an inch in thickness, very brittle, and of a brownish-yellow colour. Mr. Doubleday says that the producing insect in this case is one of the *Aphis* tribe. They are extremely astringent, but have not yet been used in dyeing.—*Eng. Cyc.* Galls originate in the puncture of an insect, *Cynips gallœtinctoria*. The puncture is effected by the ovipositor of the insect, and an egg is at the same time deposited. An interruption in the ordinary functions of the tissues of the plant takes place at the spot where the egg is inserted; the consequence is an excrescence of vegetable matter, principally tannin, formed round the egg, which furnishes a nidus for the grub or larva when hatched. When this takes place the grub eats its way out through the side of the gall. Galls are produced on different species of Oak, as well as on some other plants, as the Tamarisk; Aleppo Galls, by the female of the above Diplolepis piercing the buds of *Q. infectoria* with its ovipositor, and there depositing its eggs. These producing irritation, cause the juice of the plant to flow towards the wound, and the subsequent enlargement of the part into the form of galls round the larva. This, when fully developed, escapes by a hole which it perforates in the gall after which the vitality of the excrescence either decreases or ceases altogether. The surface has irregular elevations or lines, with the interspaces generally smooth. Galls are devoid of smell, but have a disagreeably bitter taste, with a powerfully astringent action. The whole of their soluble matter is yielded to forty times their weight of boiling water; ether dissolves about half their weight, alcohol considerably more. They yield a fine black colour with any of the salts of iron, and are used in the preparation of writing ink. The quantity imported is annually about 700 tons. The infusion possesses all the valuable properties of the gall, as does an alcoholic tincture; but decoction is an objectionable preparation. For internal use the infusion is preferable to the powder, which, like all substances containing much woody fibre, irritates the stomach. Galls may be employed in powder to form an ointment, which with opium and camphor is of great service in painful hæmorrhoids. As a tonic in intermittent fever, and as an astringent in hæmorrhagic or other discharges, galls are occasionally employed. But the most extensive use is made of them in the arts, and as a chemical test. *Quercus infectoria*, now generally acknowledged to be the species producing the Galls of commerce, is a small tree or shrub, with a crooked stem, not above 6 to 8 feet high. Leaves on short stalks, 1—$1\frac{1}{2}$ inch long, ovate-oblong, with a few coarse mucronated teeth on each side; apex bluntly mucronate, rounded, and rather unequal at the base, smooth, shining on the upper side. Acorn solitary, obtuse, 2 or 3 times longer than its hemispherical scaly cup.—A native of Asia Minor; found by Capt. Kinnier in Armenia and Kurdistan.—Nees von E. t. 94. St. and Ch. 152. Besides the names applied from the places whence they are obtained, Galls are distinguished by their physical characters, as into Blue and White Galls. The Blue Galls vary in size, and are of a bluish-grey colour. They are gathered before the insect has become perfect, or worked its way out. Some of these are larger, and are called Green Galls from being of a greenish colour. They display on their otherwise smooth surface a number of bluntly-pointed tubercles, which would appear to be the apices of leaves stimulated into unnatural growth. The best are heavy, hard, shining, and break with a short flinty fracture. White Galls are so called from being of a lighter colour than the others, but still of a greyish or yellowish hue. They are distinguished by being perforated with a small round hole, that by which the insect had escaped. They are usually less heavy than the others, have a larger internal cavity, and are not so astringent. Both are easily reduced to powder, which is without odour, but with a simple powerful astringent taste. They yield their properties to water, which is the best solvent; also to Proof Spirit, and slightly to Alcohol and Ether. From 500 parts Sir H. Davy obtained 185 parts of matter soluble in water, of which he states 130 were Tannin, 31 Gallic acid with a little Extractive, 12 of Mucilage, &c. and 12 of saline and calcareous salts, the insoluble matter,

consisting chiefly of Lignin. But a larger portion of Tannin has been obtained by other chemists, as from 30 or 40 to 60, instead of the above 26 per cent. The little colouring matter in Galls makes them particularly valuable to tanners. *Tannin, or Tannic acid*, is usually described with Galls, as existing in them in large quantity, being generally obtained from them, though a constituent of many other astringents, as Oak bark, Catechu, &c. It is the type of astringents. Ordinary Tannin is amorphous, brownish-coloured, and consists of impurities united to the Tannic acid. Pure Tannin, or Tannic (being so named because its solution reddens Litmus and effervesces with Carbonates), is sometimes white, but usually with a yellow tinge, spongy, shining, without odour, but extremely astringent. It is most easily obtained from Nutgalls by the action of Ether. It is very soluble in water and in weak Spirit. When heated, it swells up, is decomposed, leaving bulky charcoal. It precipitates Gelatine from its solutions, and combines with the gelatinous part of skin, and thus forms leather. It forms precipitates (Tannates), most of which are nearly insoluble, with most metallic oxides, and likewise with alkalis and their Carbonates, including vegetable alkalies. The mineral acids, combining with the Tannic, also form precipitates in concentrated solutions. With Sesqui-salts of Iron it is well known to form a black precipitate (ink); the Tannin of Sumach, Catechu, &c., as has been frequently mentioned, forms a very dark green precipitate with the same salts: no effect is produced on the Proto-salts. Tannin is composed of $C_{18}H_5O_9$—3HO. *Gallic acid.* Though Galls are stated by Sir H. Davy to contain about 6 per cent. of this acid, a much larger quantity may be obtained from them, because it is formed by the conversion of the Tannic into Gallic acid by the absorbing of Oxygen from the atmosphere, Carbonic being given off. It is colourless, with an acid and astringent taste, and is usually seen in the form of a grey crystalline powder. It has an astringent taste, but is of no use in tanning. Galls are powerfully astringent; seldom given internally: Dr. Royle frequently prescribed from 10 to 20 grs. of the powder several times a day, or in infusion, in the obstinate chronic diarrhœas of the natives of India. The natives themselves prescribe them in intermittents. Its tincture is much used as a test for the salts of Iron. An infusion may be employed as a Gargle, Wash, or Injection, or as an antidote to poisoning by vegeto-alkalis; but the diluted Tincture affords a more ready antidote. —*Faulkner, Royle. Tomlinson. Eng. Cyc. Mason.*

(4007) GALMENDORA. A rather hard, very fine, but not close grained, heavy Ceylon, wood.

(4008) GAMBIER; UNCARIA. (Syn. NAUCLEA) GAMBIR. (*Roxb. Fl. Ind.* i. 517. *As. Res.* xi. 187.) See CATECHU.

Gambir, Mal.

Gambier is the Malayan name of the terra-japonica, and of the plant that yields it, the Uncaria gambier of botanists. It is a native of the islands of the Indian Archipelago, cultivated in the Calcutta Garden.—*O'Shaughnessy, page* 398. The plant is a straggling shrub, from eight to ten feet high, and an object of extensive cultivation. A gambier plantation generally extends to about 30 acres, and, when full grown, has the appearance of a coppice. The drug is the inspissated juice of the leaves, obtained by boiling to the consistence of a syrup, which is poured into moulds, and, when dry, cut into cubes of an inch and a half to a side. The leaves are pulled three or four times a year, and the plantation is exhausted in fifteen years, when it is abandoned, and new land had recourse to. In Singapore, where the cultivation was established on its first occupation, in 1819, there are 800 plantations; but the culture has been largely extended to the neighbouring continent. It is, however, carried on to a much greater extent in the islands of Batang, Bintang, and Linga. Although originally a Malay manufacture, it is at present almost wholly carried on by the Chinese, who conduct the cultivation of gambier in combination with that of black pepper, the refuse leaves of the former being found an useful manure for the latter. The gambier plant appears to be a native of all the countries on the shores of the straits of Malacca, but especially of the numerous islands at its eastern end. From the last, it has been immemorially exported to Java and the islands east of it, to be used as a masticatory, being one of the ingredients in the betel preparation. It does not seem to be a production of any of the islands of the volcanic band. Gambier contains from 40 to 50 per cent of pure tannin, and hence it has been of late years largely imported into Europe, to be used in the purposes of dying and tanning, the quantity imported yearly into England being not less than 6000 tons. This is one of the striking results of the freedom of commerce, and the progress of the arts among us.—*Crawfurd, Dict. page* 142. *Gambier* is an important article in commerce, and was formerly called Japan earth in Europe. Roxburgh quotes a description of its preparation and properties by Dr. Campbell of Bencoolen, to the effect that the Malays use the gambier with betel and areca, as *kuth* or catechu is employed in India,—that the young roots and leaves are sliced and bruised in water for some hours until a feculum is deposited, this is inspissated before the sun to a proper consistence and cast in moulds of a circular form. Dr. Roxburgh adds, that in other parts the extract is made by decoction of the leaves, and evaporation by fuel and solar heat, the product dried being cut into small thin cakes. Eight species of *Uncaria* are described by Roxburgh,

and twelve of *Nauclea*. The Gambier extract is described by M. Fee as the true or Indian kino. It is but little soluble in cold water or in boiling water; it is almost entirely dissolved by boiling spirit. It gives a rose-coloured precipitate with gelatine, and a deep permanent green with the salts of iron. It is rich in the tannic, but contains no gallic acid. Its uses in the arts and in medicine depend altogether on the presence of the tannic acid. Mr. Pereira on strong grounds denies that the gambier is one of the kinos of the druggists; Ainslie regards it as the *cutlacumboo*, one of the varieties of catechu of the Indian bazars; *cashcuttee* he considers to be the produce of the betel nut tree. In 1837-38, there were imported into Calcutta from Singapore, Penang, and Pegu, 3677 maunds of gambier, at a valuation of 15,916 rupees.—*O'Shaughnessy, p.* 398. The Gambier plant (Uncaria Gambier, Roxburgh, Nauclea Gambier, Hunter), was described by Rumphius under the name of Funis uncatus. Simmonds tells us it is a stout, scandent, evergreen shrub, which strongly resembles the myrtle. It is generally cultivated in the same plantation with pepper, as the leaves and shoots, after undergoing the process by which their juice is extracted, to furnish a kind of catechu, are found to be an excellent manure for the pepper vines. The leaves and young shoots of the gambier plant are collected as soon as they have attained a sufficient size, and boiled in iron pans until the juice acquires the consistence of treacle. The decoction is poured out into narrow troughs, dried, and afterwards cut up into small cakes, and packed in baskets for exportation. The gambier extract, which is of a yellowish brown color, and has the consistence of hard cheese, is much esteemed by the Malays for mixing with the preparation of betel, which they are in the habit of chewing; and considerable quantities have lately been imported into Britain where it is used for dyeing colours, and for tanning leather. The demand for gambier there is on the increase; and when better known to chemists, it will probably be found applicable to many other purposes than those to which it is at present applied. There were, in 1850, 400 gambier and pepper plantations on the island of Singapore; each measures or occupies on an average an area of 500 fathoms square, and employs eight to ten hands to cultivate and manufacture the gambier and pepper. There are some pepper plantations in addition, and they have been found to answer very well without any gambier being cultivated with them. Gambier cultivation is generally a losing undertaking, but it is adopted to obtain the refuse of the leaves for manuring the pepper vines, and also to employ the people in the plantations; it besides affords the proprietors the means of getting monthly sums to carry on the cultivation of pepper, which affords two crops yearly. There were formerly 600 plantations in Singapore, but the reasons already assigned, and the formation of spice plantations contiguous have caused the abandonment of all those near the town. Each plantation must have an equal extent of forest land to that cultivated with gambier and pepper, to enable the manufacture of the gambier to be carried on, and each gambier plantation, of 500 fathoms square, contains about 3,500 pepper vines, which yield on an average two catties per vine, or 70 piculs of pepper, and about 170 piculs of gambier annually;—a good plantation will, however, yield sometimes as much as 120 piculs of pepper, and 200 piculs of gambier, and a bad one as little as 40 to 50 piculs of pepper, and 60 to 80 piculs of gambier. Were it not for the enormous commission charged by the agents of these plantations, from whom the cultivators get all the advances, it would prove a profitable cultivation. The rates of commission charged generally are as follows:—Per picul of gambier, fifteen to twenty-five cents; per picul of pepper, thirty to forty cents; and if the price of the former is below one-and-a-half dollars, and the latter below three-and-a-half dollars per picul, a small reduction is made in the rates of commission. On every picul of rice supplied to the planters twenty to twenty-five cents commission is charged; this includes the interest of money advanced, which is never charged. A gambier and pepper plantation is valued or estimated at about 400 dollars on an average. The following is supposed to be a correct estimate, on an average, of the yearly expenditure and returns of a gambier and pepper plantation of 500 fathoms square, viz:—

EXPENDITURE.

	drs.	c.	men.	drs.	c.
Eight men at 3½ dollars and 7 Java rupees per month, wages for headman and labourers respectively	22	70	12	272	40

PRODUCE.

170 piculs of gambier, valued at 1 dollar 45 cents per picul, less 15 cents commission chargeable, nett	221	30	—	
70 piculs of pepper, at 4½ dollars, less 40 cents per picul commission, nett	287	0	508	0

Yearly profit, 73 dollars, or about £15.

Several gambier and pepper plantations have been abandoned in Singapore, partly from the ground being impoverished, but more particularly from the exhaustion of the forests adjacent to their estates. The exhaustion of the trees by yearly consumption deprives the planters of the necessary firewood which is used for the boiling down of the gambier. A gambier plantation gets exhausted in fifteen years, either from the want of firewood or the land getting impoverished. There are about 200 plantations at Johore, and the produce of gambier for the season of 1851 was calculated at 30,000 piculs. This shrub was, at one period, cultivated with success at Pinang

and other places to the eastward, but as Java was the principal market for the produce, and the Dutch had levied a duty of twelve Java rupees per picul on it, the cultivation at the former island did not repay its cost, and it was accordingly abandoned. Prices have been lately advancing, and the Chinese are talking of trying it again. The plant is partial to hilly land or slopes at the skirts of hills. Two hundred plants are usually placed on one orlong of land, being six feet asunder. They are raised from seed, and are topped to eight or ten feet, when the gambier is to be prepared. The Chinese dry the seed slightly, and sow in rainy weather. The seeds vegetate in forty days, and are planted out in the second or third month afterwards. At the expiration of fourteen months, the first cutting of the branches, with the leaves on, is made. These are put into a boiler, and when the juice has been extracted, the branches and refuse are thrown away, and the boiling is continued until the liquor has obtained the proper consistence, when it is put into shallow troughs, dried, and cut into slices for sale. The second cutting takes place eight months subsequently to the first. The plant now grows strong and admits of frequent cropping, and it will endure for twenty years. No manure is used, but the plantation is kept clean. Estimated cost of cultivating ten orlongs, about 13 acres, according to Colonel Low :—

	Spanish dollars.
Value of cleared land, ten orlongs... ...	200
Six laborers per annum	360
Quit rent	7

Second year	397
	1,064

The six laborers on the plantation will, after the above period, be constantly employed in cutting and preparing the gambier: the average product will be 15 piculs monthly, which, at two dollars per picul, will be 30 dollars monthly, or 360 dollars per annum. This is the account obtained by collating different Chinese statements. The *Nauclea gambir* is placed by Jussieu under the natural order *Rubiaceæ*; it is a shrub attaining the height of six to eight feet, branchy; the leaves are ovate, pointed, smooth, waving, distinctly veined transversely underneath, of dark green color, and, when chewed, they have a bitter, astringment taste, leaving however, afterwards, a sweetish taste in the mouth, not unlike liquorice; the flower are aggregate, globular, composed of numerous florets, crowded on a globular naked receptacle: tubes of the corolla of a pinkish color; the upper part of the corolla fine, cleft, and of a greenish yellow color; the staminæ are five in number, and short; the pistil is longer than the corolla; the flowers are destitute of fragrance; the capsules (as correctly stated by Mr. Hunter) are stalked oblong, incrusted, and crowned with a calyx; tapering to a point below; two celled, two valved, the valves adhering at the apex, splitting at the sides; seeds very numerous, oblong, very small, compressed, furnished at both ends with a membranous pappus. The gambier plant is propagated either by seeds or cuttings, but the latter are preferred. It is cultivated to some extent at Singapore, but it is said that the gambier can be imported cheaper from the islands in the vicinity, more especially at the Dutch settlement at Rhio. The extract is used extensively by the natives of India, Eastern Archipelago, Cochin-China, and Cambodia, as a masticatory, wrapped up with the betel. There are three different qualities of extract; the first and best is white, brittle, and has an earthy appearance when rubbed between the fingers (which earthy appearance gave it the name of Terra Japonica, being supposed, at first, also, to come from Japan), and is formed into very small round cakes. This is the dearest sort, and most refined, but it is not unfrequently adulterated with sago; this kind is brought in the greatest quantity from the island of Sumatra. The second quality is of a brownish yellow color, is formed into oblong cakes, and, when broken, has a light brown earthy appearance; it is also made into a solid cube form; it is sold in the bazars in small packets, each containing five or six. The third quality contains more impurities than the preceding, is formed into small circular cakes, and is sold in packages of five or six in the bazar. The method employed in preparing the extract is thus correctly related by Finlayson :—"The leaves are collected three or four times a year; they are thrown into a large cauldron, the bottom of which is formed of iron, the upper part of bark, and boiled for five or six hours, until a strong decoction is obtained; the leaves are then withdrawn, and allowed to strain over the vessel, which is kept boiling for as many hours more, until the decoction is inspissated; it is then allowed to cool, when the catechu subsides. The water is drawn off; a soft soapy substance remains, which is cut into large masses; these are further divided by a knife into small cubes, about an inch square, or into still smaller pieces, which are laid in frames to dry. This catechu has more of a granular, uniform appearance than that of Bengal; it is, perhaps, also less pure." The younger leaves of the shrub are said to produce the whitest and best gambier; the older, a brown and inferior sort. There are other species of *Nauclea* indigenous to Singapore, but they do not produce any extract. Dr. Bennett has particularised four qualities of gambier :—1. Small round cakes, about the size of a small lozenge. Color pale, purplish, yellow-

ish white. 2. Cubes, in which shape it is principally imported into England, and square prisms, or oblong pieces. 3. Circular discs, or short cylindrical pieces. 4. Cubical amylaceous pieces, of a darker brown than the other kinds. Gambier is one of the most powerful of the pure astringents. The chief places of manufacture are Saik, Malacca, Singapore, and Rhio or Bintang. Bennett, in his "Wanderings," says there are 60,000 plantations of gambier on this island. After that of Rhio, the next best gambier is that of Lingin. That used by the Malays, with the leaves of betel, in the same manner as cutch in other parts of India, is the finest and whitest; the red being stronger tasted and rank, is exported to Batavia, China, and England, for the purposes of tanning and dyeing. It is frequently adulterated with sago powder, but it may be detected by solution in water. Large quantities of gambier are imported, under the corrupted name of cutch, into Calcutta, from Pegu. The quantity of gambier produced in Rhio, by the Chinese settlers, amounts to about 4,600 tons a year, about 2,000 of which are exported for the consumption of Java, the rest being sent to Cochin-China and other neighbouring countries. Two methods of obtaining gambier are described. One consists in boiling the leaves in water, and in inspissating the decoction; the other, which yields the best gambier, consists in infusing the leaves in warm water, by which a fecula is obtained, which is inspissated by the heat of the sun, and formed into cakes. The injudicious practice adopted by the Land Office in Singapore, of granting indiscriminate licenses, or "cutting papers" as they are termed, seems open to objection, and is driving many of the Chinese cultivators to the neighbouring island of Johore, where they readily obtain permission to cultivate, without obstruction, this important article of commerce. Parties of 300 or 400 at a time left in 1846. It appears that, under his permissive license, the squatter obtains permission to clear as much land as he possibly can, but the order does not define any extent beyond which no cutting should take place. The squatter clears as much land as the means at his disposal will allow, in the hope and expectation that the jungle contiguous to the cleared ground will be at his command for fuel—a supply of fuel, easy of access, and adequate to the number of plants grown, being indispensable to the culture and manufacture of gambier. When the time for gathering the leaves arrives, another squatter (perhaps from motives of envy or malice) obtains a "cutting paper," and commences clearing in close proximity to the already-formed gambier plantation; obviously depriving the owner of the fuel he has reasonably calculated upon. The established planter cannot of course eject the intruder from the land, since the latter possesses an equal right to it, in virtue of his "cutting paper," which, as it specifies no limits, leaves him the disposer or destroyer of the crop of the industrious planter. Instead of the present system, a better practice ought to be introduced, defining the boundaries to be included in a "cutting paper," and effectually preventing a trespass on the fuel-land of the industrious planter. This might easily be effected by specifying the number of acres, as well as the direction, in every clearing paper granted. The average produce of gambier in Singapore is between 7,000 and 8,000 piculs monthly. The ordinary price is about 1¼ dollars per picul. A deficiency of rain, labor, or other causes, will occasionally reduce the annual produce from 90,000 or 100,000 piculs, to 60,000 or 70,000, and this diminished supply will raise the market price of the article probably 35 cents per picul. But, in addition to the effect occasioned by a deficient supply, there are other causes in operation exercising a powerful influence in reducing prices. Gambier was first exported in 1830, from Singapore, to the extent of 2,587 piculs, at 4½ dollars per picul. As a rival to bark it failed at so costly a price to meet with encouragement; the culture and manufacture consequently declined until 1834, when 1,858 piculs were shipped to England at a somewhat lower rate. The demand then became active, the exportations were at first multiplied, then doubled every succeeding year, until they reached, in 1846-47 no less than 173,117 piculs. The price has gradually declined to 1¼ dollars per picul, at which rate it displaces its rival, bark. This price, however, is unremunerative to the grower, so that, unless more encouragement offers, the supply will decline. The number of Chinese employed in the cultivation, &c., of gambier and pepper in Singapore is about 11,000. Their rate of wages fluctuates with the price of gambier. If a picul of gambier realizes 1½ dollars, the monthly pay will be about three dollars; if gambier fetches two dollars, their pay will amount to four dollars in the month. The workmen who clean the plantation always receive a dollar less than those who cut and boil the gambier. A good deal of gambier seems now to be grown in Java, for 58,305 piculs were exported from that island in 1843. A small quantity is taken by the Chinese ports, but whether as a masticatory or for tanning and dyeing Simmonds is not aware.

VALUE OF THE TERRA JAPONICA IMPORTED INTO CEYLON.

	£		£
1840	611	1846	824
1841 ...	1,053	1847 ...	1,549
1842	768	1848	1,095
1843 ...	471	1849 —	896
1844	1,153	1850 — —	265
1845 ...	537	1851 —	386

In the Customs' returns of imports to this country, two articles are enumerated, under the separate names of cutch and terra japonica; the former is catechu and the latter the produce of the gambier plant. The imports of gambier

were, in 1836, 970 tons; 1837, 2,738 ons; 1838, 1,660 tons; 1839, 5,213 tons.

		Catch.	Terra Japonica.
		tons.	tons.
1848	Imported to the United Kingdom	1,186	5,823
	Retained for home consumption	765	5,102
1849	Imported	1,636	6,851
	Retained for home consumption	869	5,400
1850	Imported	1,172	4,585
	Home consumption	787	3,655
1851	Imported	2,401	4,783
	Home consumption	2,020	4,431
1852	Imported	2,236	3,244
	Home consumption	1,708	3,003

Catechu, imported under its Indian name of cutch, is brought over in bales or baskets of from one to four cwt., the price being £18 to £25 per ton. About 450 cwt. of terra japonica or gambier is annually imported into Hull from the East Indies. The imports of the two substances into Liverpool is about 900 tons. Gambier is only worth £13 to £14 the ton; a few years ago it fetched 26s. the cwt. The imports into the port of London average 1,500 tons annually. 4,679 bales, and 14,436 baskets of terra japonica were imported into Liverpool in 1851, and 14,000 bales and baskets in 1852. The imports of cutch were 10,290 bags, and 2,592 baskets, in 1851, and 11,873 bags and baskets in 1852; the prices, which were from 16s. 6d. to 18s. per cwt. for each article, in 1851, were rapidly run up in Liverpool, in 1853, owing to short supplies, to 25s. for gambier, and 22s. to 24s. per cwt. for cutch, or catechu.

EXPORTS OF GAMBIER FROM SINGAPORE, WITH THE OFFICIAL VALUE IN RUPEES.

		Piculs.	Value in Rs.
1840-41	Exported	79,508	457,560

1851	68,365	11,639	80,004
1852	68,045	9,006	77,051

The exports of cutch from Pinang, in the last four years, have been:—1849, 3,693 piculs; 1850, 900; 1851, 4,143; 1852, 3,880; or, on an average, 197 tons.—*Simmonds.*

(4009) GAMBOGE,

Ossara rewund, Arab.	Gomma gutta, It.
Gokkatoo, Cyng.	Gutami-gutte, Cambogia, Lat.
Gutte-gum, Dut.	Gomarum, Port.
Gomme gutte, Fr.	Rong, Siam.
Gummigutt, Ger.	Mukki, Tam.
Ravundchenee-Seerah, Guz. Hind.	Passapoovenny, Tel.

Camboge or Gamboge, a gum resin may be found to be the produce of several species of plants belonging to the natural order Guttiferæ. The best gamboge is brittle and inodorous, of conchoidal fracture, orange-coloured, or reddish yellow, smooth, and somewhat glistening. Its powder is bright yellow. It may be resolved into resin and gum by the successive action of ether and water. The finest gamboge contains about 70 per cent of resin, sometimes termed *gambodic acid*, which forms numerous salts. Gamboge is used as a pigment, and in miniature-painting; also to tinge gold varnish. In medicine it is used as a drastic purge. It is sometimes improperly used by confectioners to colour liqueurs. An artificial gamboge, of very little value, is manufactured with turmeric and other materials.—*Tomlinson, page* 286. Its composition is as follows; number 1 being an analysis by Professor Christison of a commercial specimen from Ceylon; number 2 of a fine sample of common ditto:—

	1.	2.
Resin, or fatty acid,	78·84	74·8
Colouring matter,	4·03	3·5
Gum,	12·59	16·5
Residue,	4·54	5·2
	100	100

The average imports of gamboge into the port of London, during the past five or six years, have been from 400 to 500 chests of one to two cwt each.—*Simmonds.* Mr. Mason remarks that three works in his possession describe gamboge, each as the product of a different tree; a fourth represents all to be wrong, and a fifth suggests a different plant still. One refers it to *Cambogia gutta*, a plant which, as described by Linnæus, has probably no existence. He described a Ceylon plant, "and it is now quite evident," says Dr. Wight "that the character of the flower and ovary is taken from one specimen, and that of the fruit from a different one, owing to the imperfection of his specimens, and his not being aware, that the lobes of the stigma afford a sure indication of the number of cells of the fruit." Another, refers it to *Garcinia Cambogia*, but Dr. Wight says, that the exudation of this tree is "wholly incapable of forming an emulsion with the wet finger," a statement known to be correct. The tree is very common in the Tenasserim Provinces, but the bright yellow exudation it produces, is certainly not gamboge. A third, refers it to *Stalagmitis Cambogioides*, but Dr. Wight remarks: "The

juice of this tree differs so very widely in its qualities from good gamboge, that it can never be expected to prove valuable as a pigment." Dr. Graham has described a Ceylon tree under the name of *Hebradendron Cambogioides*, which is said to produce good gamboge; but no gamboge has ever been exported into the English market from Ceylon. Thus it would appear, to use the language of Dr. Wight, that "the tree, or trees, which produce the gamboge of commerce, is not yet known." Dr. Helfer, who was employed by government as a scientific naturalist in the Tenasserim Provinces, reported: "The gamboge of this country dissolves very little with water, and consequently does not yield a yellow emulsion as the common *guttiferæ*. It will never serve as a colour, but promises to give a very beautiful varnish." This statement was controverted by a writer in a local periodical at the time, who said he had obtained "fine gamboge of the very best description" from our jungles: in which he was no doubt correct, but he erred when he added, that it came from the "true *Stalagmitis Cambogioides*;" for that plant has a quinary arrangement of its flowers, while the arrangement of the flowers in those that produce gamboge, in these Provinces, is quaternary. The hills that bound the valley of the Tavoy river, on both sides, from their bases to their summits, abound with a tree which produces a bright gamboge. It is Roxburgh's *Garcinia pictoria*, which he knew produced gamboge, but which he said was liable to fade. As soon as Mr. Mason had satisfied myself of the identity of the trees by an examination of the inflorescense of the Tenasserim plant, compared with Roxburgh's description; he coloured a piece of paper, one band with this gamboge, and another with the gamboge of commerce; and subsequently exposed both to the weather equally for more than twelve months, but without being able to discover that one faded any more than the other. South of the mouth of Tavoy river, and throughout the province of Mergui, there is found on the low plains at the foot of the hills, and on the banks of the rivers, almost down to tide waters, another species of garcinia that also produces good gamboge. He has no doubt but it is the tree from which Dr. Griffith furnished Dr. Wight with specimens, and of which, the latter says, "I refer doubtfully to Wallich's *G. elliptica*." We will call it then *G. elliptica*, a species which Dr. Wight has on his list of "species imperfectly known." The foliation and female flowers are, however, very well described, and to complete the description, I may add, the male flowers are pedunculated, but the peduncles are short, and they might be characterized as sub-sessile. The anther, like those of the female flowers, are sessile, depressed or flattened above, and dehisce circularly. The ripe fruit is globose, and not furrowed. Neither Wallich, Wight, nor Griffith appear to have been at all aware that gamboge was a product of this tree. Dr. Wight, in a recent number of his Neilgherry Plants, says: "Two species of the genus garcinia are known to produce gamboge, most of the others yield a yellow juice, but not gamboge, as it will not mix with water." The species which he has described as producing gamboge, and to which Mr. Mason supposes he refers, are *G. gutta*, or *H. Cambogioides*, (Graham,) and *G. pictoria*, (Roxburgh) In its appearance to the eye, and in its properties as a pigment, Mr. Mason has failed to discover the slightest difference between the exudation of this tree, and the gamboge of commerce. The Burmese priests use it occasionally to dye their robes, the Karens their thread, and it serves equally well in colouring drawings. It is also used by the native doctors in medicine, but not extensively. Dr. Lindley, in his new work the Vegetable Kingdom, says: "The best gamboge comes in the form of pipes from Siam, and this is conjectured to be the produce of *Garcinia Cochinchinensis*." Now as *G. elliptica* is spread all over the province of Mergui, is it not probable that it also extends into Siam, and that the Siamese gamboge is the product, a part at least, of this tree? Specimens of the gamboge were sent up with the above communication to Calcutta, and the Secretary of the Asiatic Society wrote in reply: "Our best botanists here, consider that you have hit upon the true tree at last."—*Mason.*

Another gamboge tree has recently been found inhabiting the western Burmese territories. Both these seem to furnish an equally fine pigment. As it can be obtained in unlimited quantity, it might be introduced into European trade, if the natives learn how to collect it in a state of purity, and make it up in homogenous masses in imitation of pipe gamboge, the finest Siam variety. It seems to possess more coloring matter, more resin and less gum, than the ordinary gamboge of commerce. Gamboge owes its color to the fatty acid. The resin must be regarded as the chief constituent and is most abundant in that imported from Ceylon which contains about 76 per cent. and is therefore best adapted for painting. Gamboge also has its medicinal uses. *Xanthochymus ovalifolius*, according to Wright and Arnot, is the only plant in Ceylon that yields gamboge fit for the arts, is found in the Rangoon, Pegu and Tounghoo districts, but it is rather scarce. *X. pictorius*, which is very plentiful, also yields gamboge, but probably of a less valuable description, as also *Garcinia Cowa* or wild Mangosteen tree, which is likewise common. —*McClelland.* We are assured by the Rev. Mr. Mason, Mr. O'Reilly and other observers that the gamboge trees (G. elliptica) are dispersed through the forests of Burmah, in such numbers as to afford a considerable quantity of the exuda-

tion, did the knowledge of its value and the process of preparing it, exist with the natives, (Kareans) the tree is, however, felled indiscriminately with the rest of the forest, in the annual clearings which take place, and the article which forms a prominent item, in the rich exports from Siam, is on the eastern side of the border range utterly neglected and destroyed. The districts where the Burmese gamboge is produced, are nearly in the same latitude with Cambodia where the commercial gamboge of Siam is known to be produced. The Koorg or Wynaad gamboge tree has an extensive range, Dr. Cleghorn has seen it along all the higher parts of the Malabar Ghauts, extending fully 120 miles, from north to south, and in some parts it is very abundant. The produce for the most part, is made little use of, and the tree is considered of so small a value, that he has seen the supports and scaffoldings of bridges, &c., entirely composed of the *Garcinia pictoria*, though from the valuable observations of Dr. Christison, this gamboge "may be advantageously applied to any use to which the gamboge of Siam, is habitually put." This article is now coming much into use as a pigment, and as the exudation can be obtained in large quantity, it may be introduced into European trade, when once the natives learn how to collect it in a state of purity, and make it up "in homogeneous masses in imitation of pipe gamboge, the finest Siam variety:" This is imported in the bamboos, in which it is moulded, or in fragments of pipes—or in lumpy masses, but always homogeneous. The earliest notice of gamboge as a remedial agent, is contained in the rare and valuable work of Garcias ab Horto, Physician to the Viceroy of Goa, where he says, "magnaque apud incolas illius est laus in curationibus, &c." Again, in Ainslie's Materia Medica, second edition, I find that Dr. S. Dyer, when Garrison Surgeon at Tellicherry, transmitted this valuable substance to Dr. Roxburgh, but the specimens seem to have been impure. In a foot note to his account of this drug, Ainslie further remarks, "Colonel Wilks informs me that this yellow gum resin had been previously noticed by the pioneers of Lord Wellington's army." It is *surprising* that this product should have been so little attended to, as the value in London price currents varies from 3*s*. 6*d*. to 5*s*. per pound. The names of the trees producing the gamboge and kino, should be added to the list of trees protected from indiscriminate destruction, which list is at present confined to the teak, ebony, black-wood, and sandal-wood. In two papers, read before the Royal Society of Edinburgh, in March and December, 1836, Dr. Christison gave an account of the composition and properties of the gamboge of Ceylon, showing that in both respects it is identical, or very nearly so, with the more familiar gamboge of Siam, the only kind met with in European commerce, and proving that certain other gamboge oid exudations from *Garcinia Cambogia*, *Xanthochymus pictorius* and *Xanthochymus spicatus*, although they have been supposed closely to resemble ordinary gamboge, are really quite different in appearance, nature, and composition, as well as unfit for any of the well-known economic uses of that substance. Though desirous of extending these inquiries also to the analogous products of other plants of the same natural family, the *Guttiferæ* and more especially of examining the exudations, said to resemble gamboge, which have been observed by officers of the East India Company's Service—first, on a tree in the forests of the Wynaad, in the western part of Mysore—and, secondly, on one inhabiting the western Burmese territories, ceded to the Company after the last Burmese war, for a long time Dr. Christison's efforts to obtain the necessary specimens and information were unsuccessful. In the interval some advance has been made by Dr. Wight, of Madras, towards determining the nature and botanical source of the supposed Burmese gamboge. This branch of the inquiry is, perhaps, of more practical interest than any other. For the districts where the Burmese gamboge is produced are nearly in the same latitude with Cambodia, where the commercial gamboge of Siam is known to be collected; the two localities are even at no great geographical distance from one another; and hence, were a true gamboge found to be produced on the western coast of the Burman Empire, a strong presumption would arise that its tree is the same with the unknown gamboge tree of Siam. Upon this point Dr. Wight in a letter of the date of January, 1843, observes —"I have lately received flowering specimens of *Garcinia elliptica*, of which I have published a figure in my *Icones*, as the gamboge-tree of Tavoy and Moulmein, and not improbably of Siam. There was sent along with the specimens a very small quantity of the juice, which was quite emulsive, although in itself a very bad and dirty sample. On trial it could be used readily as a pigment; but the colour was bad, whether naturally so, or owing to dirt with which it was mixed, I could not make out. The specimen was too small for me to examine thoroughly. A further and better supply was promised me. But the gentleman who interested himself in the inquiry was shortly after removed from that coast; and there the matter dropped. All the other juices of the *Guttiferæ* I have examined are resinous and do not mix with water, in short are not emulsive." In the month of May of 1841, Dr. Christison at length received intelligence of the gamboge of the Wynaad, and soon afterwards authentic specimens, of small size, yet sufficient for determining its nature and leading properties. With these materials he made a short investigation without delay; and in December the results

were communicated to the Royal Society of Edinburgh. But he more lately received, additional information and specimens from Dr. Hugh Cleghorn, of the Madras Medical Service; who thus enables him almost to complete the inquiry. While residing not long ago at Cannanore, Mrs. Walker learned from a party of the Company's Engineers, that they had observed what seemed to be a gamboge tree in the jungles of the Coorg country. This party had been for some time employed, under the command of Captain Cotton, Lieutenant Francis, and Lieutenant Walker, in tracing a projected road from Mysore, through the unfrequented jungles of the Coorg Ghauts, towards the Malabar Coast. In these operations they had to "penetrate dense forests, abounding with trees producing vast quantities of gums and resins," and, among the rest, with the tree in question. Lieutenant Francis states, that this tree was seen almost everywhere on the route from Cannanore to the Ghauts of the Coorg country, and that at one place their encampment in the forest was quite surrounded by it. From this gentleman Mrs. Walker received a small specimen of the exudation, and he added the remark, that he "could not detect any difference between it and the colour-markers' gamboge in tint; but on putting the brush into the mouth, it does not burn as it ought to do." Dr. Cleghorn's observations were made last autumn, while accompanying in his professional capacity Captain Le Hardy, in the north-west district of Mysore, near Nuggur. He observes, in his first letter, dated from that place on the 3d March—"When accompanying Captain Le Hardy, in his annual tour, the gamboge-bearing tree was first observed near the north-western frontier of Mysore, as we were proceeding through an interesting, almost unexplored country, everywhere affording the most picturesque scenery, covered with jungle more or less dense, supplying abundant materials for the botanical traveller, and especially remarkable for the Gairsoopah Falls, where the river is precipitated over a vertical scarp 900 feet in height. * * The tree, which grows to an elevation of thirty or fifty feet, was met with along the tops of the Ghauts from Gairsoopah to Nuggur, a distance of fifty miles; and I understand it grows in greater abundance ten miles southward of this. It would appear that its range of elevation is between 2000 and 3000 feet, though it has also been seen sparingly on the sloping descent for some distance down the Ghaut. It is generally found in thick jungle, overtopped by the sago-palm and other forest trees of great height. The foliage is dense, the branches shoot out horizontally, two or three occasionally coming off in the same plane; and in general contour it reminds me in some measure of the box on a gigantic scale." In a subsequent letter, dated at Augoombee, 22d March, Dr. Cleghorn adds, that he found the tree in still greater abundance as he proceeded southward; and in another, dated a month later, he remarks, that on leaving the cool and humid range of the Western Ghauts, whose moist and shady slopes seem to afford a congenial climate, he lost sight of the gamboge-tree entirely. From a variety of accounts collated by Mrs. Walker, it has evidently an extensive range, having been met with by the engineer party along a tract of hilly country extending nearly 120 miles from north to south. It seems to flower during the rainy season of the monsoon; at the close of which the yellow juice is said to be exuded in greatest abundance. It is called in the Canarese language *Goorgeemara*, or yellow gum-tree. The specimens of the juice sent to Dr. Christison were all in the concrete state. Those sent by Mrs. Walker present, on a fresh surface, a tawny, brownish-yellow colour, and glistening waxy lustre, exactly like fine Siam gamboge; and they show a tendency to the conchoidal fracture. They are free of odour, and, in correct language, tasteless; but he has not found them destitute of acridity, as Lieutenant Francis did; for in a few seconds after testing a small portion an acrid impression was produced in the back of the palate, like what is occasioned by Siam gamboge. The Mysore gamboge is emulsive. Mrs. Walker's specimens are not quite so easily reducible to a fine emulsion with water as the superior qualities of that from Siam; but the subsequent specimens of Dr. Cleghorn seem to him not at all inferior in this respect to the best commercial gamboge. The emulsion presents the peculiar, brilliant, intense yellow hue of ordinary gamboge. When it is used as a pigment, he is unable to detect the slightest difference in tint from that variety. He put it into the hands of a skilful colourist, along with a specimen of the finest pipe-gamboge of Siam, of a quality seldom met with in the colour-shops; and he received an opinion that the Mysore gamboge was not so easily rubbed down, and that upon paper the tint presented the slightest possible shade nearer brown; but nevertheless that it appeared a superior gamboge, undistinguishable from the gamboge of the shops except on the most narrow inspection. In stating this opinion, it is necessary to add, that the standard of comparison had obviously been collected with the greatest care, while Mrs. Walker's specimen had not this advantage, analysis proving it to be not quite pure; and that the specimen from Dr. Cleghorn, which proved to be considerably purer, is evidently more emulsive. The analysis of these specimens was performed nearly in the same manner as that of the Ceylon and Siam varieties, of which an account was given in my paper in 1836. These were found to consist essentially of an orange-coloured resin,

very soluble in sulphuric ether; of gum, which is entirely and easily soluble in water, and of a little adhering moisture. But the Ceylon gamboge also contained more or less woody fibre, accidentally present, owing to want of due care in collecting it; and the inferior qualities of Siam gamboge contained varying proportions of ligneous fibre and starch, owing to adulteration with the flour, probably of some leguminous seed. Since this analysis was executed, the same subject has been taken up by Dr. Ph. Buchner, who examined specimens of Siam pipe-gamboge and common Ceylon gamboge, presented by me to Professor Liebig; and he found, besides the proximate principles observed by me, a trace of brown colouring matter in the Siam specimen, and about four per cent. of a similar principle in that of Ceylon. He found this substance both in Ceylon and Mysore gamboge. A fine sample of the former, prepared under Mrs. Walker's instructions when she resided at Colombo, contains three and a half per cent. of this matter, and has the following composition—

Resin, ...	74·8
Gum, ...	16·5
Colouring matter,...	3·5
Accidental Fibre, ...	2·2
Moisture, ...	4·0
	101·0

One hundred grains were used; the excess over which is owing to the obstinate adhesion of ether to the resin even at an elevated temperature. The colouring matter is obtained, after removal of the resin with ether, by acting on the residue with rectified spirit, and then evaporating off the spirit from this solution. The solution is colourless; but there is left a dark smoke-brown extractiform substance, which is soluble in water, and imparts to the water a brown tint. The Mysore gamboge, like that of Ceylon, is in a great measure soluble in sulphuric ether, to which it communicates a fine orange colour; and the solution yields, when evaporated, an orange-coloured resin, identical in appearance with that from Siam gamboge. From the residuum, rectified spirit, without acquiring any colour, removed a substance which was deposited on evaporation in the form of a dark smoke-brown extract, like that obtained from the gamboge of Ceylon. The matter unacted on by the spirit, immediately formed an emulsive solution with cold water, which, when evaporated, left an adhesive transparent substance, possessing the general properties of gum. Dr. Cleghorn's specimen left scarcely any residuum after the action of cold water; but that obtained from Mrs. Walker left about three per cent. of particles of fibre and sand. From an analysis of 20 grains of each sample, a quantity however scarcely sufficient to yield very positive results, the Mysore

gamboge seems to have the following composition—

	I.	II.
Resin,...	77·0	80 0
Gum, ...	14·0	14·0
Colouring matter, ...	5·0	5·0
Fibre and Sand, ...	3·0	0·5
Moisture, ...	Not determined.	
	99·0	99·9

This composition is essentially the same with that of Ceylon gamboge, but indicates more colouring matter, more resin, and less gum than in the gamboge of commerce. These differences, however, do not materially affect its emulsive property; and as for the brown colouring matter, this seems scarcely to injure the purity of its hue as a pigment; for the brown colour is not developed until the principle has been detached by alcohol, and dried under exposure to the atmosphere. It remains to inquire whether the Mysore gamboge possesses the remarkable effects of the Siam and Ceylon varieties on the animal body. [Since Dr. Christison's observations were made, Dr. Cleghorn employed the Mysore gamboge in the Jail at Shemogah, and has seen it used frequently in the Royal Infirmary of Edinburgh. The therapeutic effects were found to correspond exactly with those of the Siam variety, and the indigenous product is now regularly received at the Medical Stores of the Madras Presidency.—H. C.] Dr. Christison's supply would not allow of many trials being made of its virtues: but three grains, triturated with a little bitartrate of potash, produced one copious evacuation; four grains had the same effect. In another case four grains failed to move the bowels; and in another, five grains occasioned five profuse discharges. In every instance tormina and sickness were caused; and one person had several attacks of vomiting. The discharges were invariably very watery, yellowish, and abundant. This gum-resin, therefore, seems to exert the same action, attended with the same inconveniences, as ordinary gamboge. It is put to very little use in India. According to the inquiries from correspondents, the inhabitants of the district where it grows, are not acquainted with its action on the animal body. Neither is it used as a pigment. But Dr. Cleghorn was informed by "an intelligent native from Canara, that the juice of the tree is occasionally used for colouring cloth in the low country," though not above the Ghauts; and a concrete oil obtained from the seeds is used, both in lamps and in making curries. From the observations made above, however, it is probable, that this gamboge may be advantageously applied to any use to which the gamboge of Siam is habitually put. At all events, it is an equally fine pigment; and as it may evidently be obtained in almost unlimited quantity, it may be intro-

duced equally into European trade, once the natives learn how to collect it in a state of purity, and make it up in homogeneous masses in imitation of pipe-gamboge, the finest Siam variety. Respecting the botany of this subject, in 1836, Dr. Graham, came to the conclusion, that what is described above, under the name of Ceylon gamboge, is produced by a plant, of which Linnæus in the first instance, and afterwards Murray of Gottingen, had given an incorrect account in consequence of their having confounded two very distinct species under one description, and which Dr. Graham was led to view as a species of a new genus under the name of *Hebradendron gambogioides*. There can be no doubt of the error both of Linnæus and of Murray. But some botanists have considered Graham's characters of his genus as not sufficiently distinctive; and in particular Dr. Wight maintains that its characters are not such as to justify a separation of the species from the genus *Garcinia*. Both Dr. Royle and Dr. Lindley, however, have admitted Graham's genus. On the merits of this question, it may be simply observed, that if Dr. Graham's new genus be a good one botanically, it appears to be also a convenient one in respect of its products; for every true gamboge-bearing tree yet known, so closely resembles his plant, that there is a difficulty in establishing even specific distinctions between them. A very different species, the *Garcinia Cambogia* of Roxburgh, once supposed to produce gamboge, and indeed actually confounded by Linnæus with the true gamboge-tree of Ceylon, Dr. Christison has proved not to produce gamboge at all; its concrete juice being a very pale-yellow gum-resin, containing volatile oil, and not in the least degree emulsive. But the *Garcinia elliptica* (*Wallich*) of Tavoy and Moulmein, which certainly produces an exudation resembling commercial gamboge, approaches very closely in its characters to Graham's *Hebradendron*; as may be seen on comparing the drawings of both in Dr. Wight's *Illustrations of Indian Botany*, Table 44, and *Icones Plantarum Indiæ Orientalis*, Table 120. The chief differences are, that in the Ceylon plant the flowers are "apparently verticelled round the articulations of the branches where the leaves have fallen (Wight,)" while in the *G. elliptica* they are axillary and solitary; and that the leaves of the former are "obtusely attenuated at both ends, and vary from broad lanceolate to rhomboidal (Wight)," while in the latter they are "three times as large, obtuse, little attenuated at both ends, and shortly and abruptly acuminated." But the resemblance is even greater than Dr. Wight's description and drawings would imply; for in four specimens of the Ceylon plant which I have had an opportunity of examining, the old leaves are not all attenuated at the apex, but abruptly subacuminate; which character indeed, though neglected by Dr. Wight, has been introduced among the specific characters of *Hebradendron gambogioides* by Dr. Graham. In like manner the Mysore tree bears an exceedingly close resemblance to that species. The resemblance indeed is so close, that the gentlemen of the party who discovered the tree on the Ghauts of Mysore, consider it to be the same with the tree of Ceylon; and Dr. Cleghorn has communicated a letter on the subject from Dr. Wight, who, from incomplete data, however, seems inclined to the same opinion. But plants, growing in different countries so distant from one another, may be more safely regarded as belonging to distinct species until they are proved to be identical. And in the present case Dr. Christison apprehends they will be found to be distinct, as the following description may help to show—The botanical specimens consist of twigs without flower, but with fruit, and of detached fruit of full size, some dry, others preserved in brine; and Dr. Cleghorn has added a drawing by a native artist. The leaves are opposite, petiolate, elliptic-lanceolate, attenuated at the base, obscurely subacuminate, four inches and a half along, and two and a quarter broad when of full size, smooth, and somewhat coriaceous. The fruit, which is of the size of a cherry, is axillary, sessile, subrotund or slightly ellipsoidal, supported by a persistent calyx of four coriagous subrotund, ventricose sepels, and crowned by a persistent, four-lobed, prominent, irregularly tubercled stigma. It is four-celled, and each cell single-seeded. In all my specimens of fruit the seeds had aborted, so that I cannot describe them. Scanty as these characters are, they indicate several points of distinction between this tree and Graham's *Hebradendron gambogioides*. For the full-grown leaves of the latter are somewhat obovate, subacuminate, and much more coriaceous; the sepals of the persistent calyx are membranaceous; and the persistent stigma of the fruit is broader, as well as very flat, and each lobe presents a regularly beaded circumference, with a depressed centre. The two stigmata are represented on the drawing of the Mysore plant. It seems very probable that this plant is the same with the *Garcinia pictoria* of Roxburgh's *Flora Indica*, which was described from specimens and information supplied by Mr. Dyer of the Company's Medical Service, while he resided in the Wynaad, where the species described above, grows. The description of Roxburgh, so far as it goes, corresponds very exactly with the specimens sent to Dr. Christison and so does a drawing of a twig and detached fruit, which was presented by Mr. Dyer to Dr. Royle, and submitted to Dr. Christison's inspection by the latter gentleman. Roxburgh indeed observes, that the gamboge from this species sent to him by Mr. Dyer was inferior in quality, and when used as a pigment, proved

to be not permanent; while the Mysore gamboge in Dr. Christison's possession, is both brilliant at first when used on paper as a colour, and has remained quite permanent for fifteen months. But Dr. Royle informed him, that Mr. Dyer himself did not agree in opinion with Roxburgh, and ascertained that his gamboge is permanent in tint when employed as a water colour. If Dr. Christison be right in conjecturing the two plants to be the same, and Graham's new genus be a good one, the Mysore gamboge tree will constitute a third *Hebradendron*, and its name will be *H. pictorium.—Pharmaceutical Journal, for August*, 1846, *Vol.* VI. *No.* 2. At the Madras Exhibition of 1855, *Gamboge*, was exhibited from Goa, Malacca, Labuan, Coorg, Canara and Mysore; that from Malacca was the best, in pipes—the others from Mysore, &c. all in lumps, the results of a variety of modes of preparation—one specimen is full of air vesicles, and of a dark colour, damaged by being collected in rainy weather. The Indian peninsular specimens are known to be produced from *Garcinia pictoria*, and are of excellent quality. Mr. Maltby, Collector of Canara, states that "it is to be found in the greatest abundance along the whole line of the Western Ghats, and it is probable that, if the attention of the trade were directed to those provinces, it might become an important article of export." Gamboge in tears is exhibited from Labuan, it has a different tint, and is probably obtained from a different tree, *Garcinia Cochinchinensis*. A specimen from Malacca exhibited by Lieut. Evans, 51st N. I., was the finest pipe variety, all the others were in the form of lumps or tears. The series was very instructive, showing how much the commercial character of this product may be altered by trivial circumstances, the exudation being yellow, reddish, or brown, and of different degrees of solidity, according to the season of the year, and the method of manipulation. The peninsular Gamboge is a useful pigment, and an effective purgative, and has been lately added to the list of country medicines. It appears that the tree is so abundant along the crest of the ghauts, that the product may be obtained in very considerable quantities in the forest of Mysore, Malabar, and Canara. Apothecary Wrightman, collected this product with much care, in homogeneous masses without air vessels, and free of woody fibres or other impurities.—*M. E. J. R.* According to Simmonds, page 451, *Gamboge* is extensively used as a pigment, from its bright yellow color. There are two kinds known in commerce, the Ceylon and the Siam. The former is procured from the *Hebradendron Cambogoides*, Graham; a tree which grows wild on the Malabar and Ceylon coasts, and affords the coarsest kind. The pipe gamboge of Siam is said to be obtained from the bruised leaves and young branches of *Stalagmites cambogoides*. The resinous sap is received into calabashes, and allowed to thicken, after which it is formed into rolls. Several other plants, as the *Mangostana gambogia*, Gaertner, and the *Hypericum baccifer-um* and *Cayanense*, yield similar yellow viscid exudations, hardly distinguishable from gamboge and used for the same purpose by painters. The *Garcinia elliptica*, Wallich, of Tavoy and Moulmein, affords gamboge, and approaches very closely in its characters to Graham's *Hebradendron*. In like manner the Mysore tree bears an exceedingly close resemblance to that species. It is common in the forests of Wynaad in the western part of Mysore, and has been named by Dr. Christison *Hebradendron pictorium*. Another gamboge tree has recently been found inhabiting the western Burmese territories. Both these seem to furnish an equally fine pigment. As it can be obtained in unlimited quantity, it might be introduced into European trade, if the natives learn how to collect it in a state of purity, and make it up in homogenous masses in imitation of pipe gamboge, the finest Siam variety. It seems to possess more colouring matter, more resin and less gum than the ordinary gamboge of commerce. Gamboge owes its color to the fatty acid. The resin must be regarded as the chief constituent, and is most abundant in that imported from Ceylon, which contains about 76 per cent., and is therefore best adapted for painting. Gamboge has also its medicinal uses.—*Simmonds, p.* 451. Gamboge fetches, in the London market from £ 5 to £ 11 per cent, and the average imports from 1847 to 1852 were from 400 to 500 chests of one to two cwt. each.—*Simmonds, pp.* 639 *and* 640.

(4010) GAMBOGE BUTTER—GARCINIA PICTORIA (Roxburgh.)

Mukki-tilum, TAM. | Arasinagoorghy yennai, CAN.

The solid butter, contained in the seeds of the "Gamboge tree," a species closely allied to the G. purpurea which produces the "cocum butter" has attracted attention. The Gamboge tree grows abundantly in certain parts of the Mysore and Western coast jungles. The oil, which is procurable in moderate quantities, is prepared by pounding the seed in a stone mortar and boiling the mass, until the butter, or oil rises to the surface. Two and a half measures of seed should yield one seer and a half butter. In the Nuggur Division of Mysore, it is sold at the rate of As. 1-4 per seer of 24 Rs. weight, or at £36-6 per ton, and is chiefly used as a lamp oil by the better classes of natives, and by the poor as a substitute for ghee. The butter thus prepared does not appear to possess any of the purgative qualities of the Gamboge resin, but is considered an antiscorbutic ingredient in food. —*M. E. J. R.*

(4011) GANGES, VALLEY. Along the sandy shores of the Ganges valley the ever-present plants are mostly English, as Dock, a Nas-

turtium, Ranunculus sceleratus, Fumitory, Juncus bufonius, Common Vervain, Gnaphalium luteo-album, and very frequently Veronica anagallis. On the alluvium grow the same, mixed with Tamarisk, Acacia Arabica, and a few other bushes.—*Hooker, Him. Jour. Vol.* 1. *p.* 80.

(4012) GANJAH.

Kanub, ARAB.	Gindshee, JAV.
Ganja, BENG.	Gingi-lacki-lacki, MAL.
Mafuen, Chutsao, CHIN.	Ganjica, Bijeeah, SANS.
Ganja, DUK.	Ganjahchettoo, TEL.
Sjarank, EGYPT.	Ganja, TAM.
Ganza, GUZ. HIND.	See CANNABIS. HEMP:

The dried hemp plant which has flowered, and from which the resin (*see* churrus), has not been removed, is called *Ganjah.* The bundles of Ganjah are about two feet long, and three inches in diameter. The colour is dusky green, the odour agreeably aromatic, the whole plant resinous, and adhesive to the touch. Ganjah is used chiefly for smoking. The narcotic effects of the hemp plant are popularly known in the North of Africa, South America, Turkey, Egypt, Asia Minor, India, and the adjacent territories of the Malayas, Burmese, and Siamese. In all these countries, hemp and its products, are used in various forms, by the dissipated and depraved, as the ready agent of a pleasing intoxication.—*Faulkner.* The leaves or young leaf buds of the hemp-plants, are smoked by itself, or rubbed between the hands and added to tobacco, to increase its intoxicating powers.

(4013) GAO-LOCHAN, Gall stones, extracted from the gall bladders of dead cows: much used in medicine: also in charms; and in painting.—*Gen. Med. Top. p.* 136.

(4014) GARCINIA, a genus of Plants belonging to the natural order *Guttiferæ*, named in honour of Dr. Garcin, who travelled in the East Indies. It formerly consisted of few species, but no less than 21 are enumerated by Dr. Wallich, 10 of which he considers new. These are distributed over the islands of the Indian Archipelago, in the southern parts of China, in the Indian and Malayan peninsulas, in Assam and Silhet, with one species (G. Cowa) extending as far north as Monghir on the Ganges. They are all trees of considerable size, with opposite coriaceous shining oval leaves; numerous flowers, which are monœcious or dicœcious; in the male, stamens numerous, inserted on a large fleshy 4-lobed receptacle, anthers bursting longitudinally; in the female, stamens numerous but imperfect, ovary 4-10-celled, ovules solitary. The fruit fleshy and juicy, crowned with the peltate stigma, is edible in many of the species.—*Eng. Cyc.* Garcinia gambogia *G. Cowa, G. lanceæfolia, G. Kydia, G. pedunculata,* and *G. paniculata,* all yield a kind of edible fruit, but of these the last is most like the Mangosteen. From incisions made in the branches a yellow juice exudes, and soon concretes, having a close resemblance to, and in fact forming an inferior kind of gamboge; whence it has been inferred that the commercial gamboge is yielded by the species. Later investigations have proved the incorrectness of the opinion, and the true gamboge-tree of Ceylon has been determined to belong to a new genus named *Hebradendron. G. Zeylona, G. cornea,* and *G. pictoria* (the last also supposed to be a species of *Hebradendron*), all yield an inferior kind of gamboge.—*Eng. Cyc.* Dr. Wight gives Garcinia Cambogia, 960-1; conicarpa, 121; cornea, 105; cowa, 104; elliptica ? 12; Kydia, 113, 960-1; Kydiana, 113, 960-1; lanceæfolia, 103; Merguiensis, 116; paniculata, 112 papilla, 960-1; pedunculata, 114-115; pictoria, 102; Roxburghii, 104, 960-1.

(4015) GARCINIA, a timber tree, of this genus, the largest that Mr. Mason has seen of the genus garcinia, is in frequent demand for house posts in Tavoy.—*Mason.*

(4016) GARCINIA CAMBOGIA, Willd.

Koorka poolie, TAM. and MAL.	Velaitie umlie, DUK.
Wontay, CAN.	Woda Chintakaia, TEL.
	Racta Shrava, SANS.

Garcinia Cambogia has elliptic leaves tapering to both ends, terminal solitary flowers, yellowish corollas, an 8-lobed stigma, the berry 8-furrowed. It is a native of Malabar and other parts of the East Indies. It is a tall tree with a trunk as thick as two men can compass, with spreading opposite branches. The leaves are 5 inches long and half that in breadth. The fruit is about 2 inches in diameter, drooping on peduncles, 1 inch in length; the rind is thin, smooth, and yellowish, the pulp is yellow, succulent, sweet, and eatable. It is very common about Siam and Cambodia, where incisions are made in the bark, and a quantity of gum-resin, called Gamboge, flows out, and is exported to foreign countries. It is called by the natives of Travancore Gharka Pulli, and is therefore inferred to be the *Curca Pulli* of old writers. In Ceylon the fruit is called Goraka, and much used by the natives in their curries; when ripe it is said to form a fine fruit as large as the Mangosteen. Mrs. Colonel Walker, in her letters to Dr. Graham, describes the outer husk of the fruit as being prepared by the natives by taking out the pulp and seeds, bruising and then heaping it up until the whole is soft. It is then smoked and kept within the influence of smoke, being much used as a favourite ingredient in their curries and also for preserving, along with salt, a small kind of fish, which thus cured will keep for six or seven months. The name *Cambogia* is derived from the province Camboja, or Cambodge, whence it comes.—*Eng. Cyc.* This species of garcinia is known in Tenasserim as the yellow varnish tree, and has often been mistaken for the tree which produces gamboge. It is very abundant through-

out the Provinces, and the gum resin which it yields when dissolved in spirits of turpentine, affords a beautiful permanent yellow varnish for metallic surfaces.—*Mason.* Its pleasant tasted though acid fruit, is about the size of a small orange and is used by the inhabitants of Malayalum and Ceylon, for the same purposes that Tamarinds are on the Coromandel coast.—*Ainslie, page* 226.

(4017) GARCINIA CORNEA, has oblong elliptic leaves, solitary and umbellate flowers, lateral, terminal, and drooping; the stigma entire; the berry the size of a plumb. It is a native of the East Indies in the high remote mountains of Amboyna. The trunk of this tree is very lofty, but not very thick, it is covered with a black bark. The branches extend wide, and divide into many short branches, which have a pair of leaves at each joint, these are large, from 11 to 15 inches long and 4 inches broad, but on old trees shorter, smooth, firm, and shining. The flower rises between the upper leaves, drooping, having the form of a small rose, of a yellow colour. The fruit is crowned by the entire stigma, which appears like a wart. It is of a dusky-brown or smoky colour on the outside, and within it has a mucous pulp, in which lie a few seeds in the shape of a half-moon. It has a resinous smell when fresh. The wood is heavy, and very hard like horn; it is used for the handles of tools, and the young ones building, the old ones being too hard to work.—*Eng. Cyc.* Of this species there were two trees in Col. Kyd's garden, Calcutta, said to have come from Malacca, and to exudea yellow juice.—*O'Shaughnessy, pages* 235, 236.

(4018) GARCINIA COWA.

Toun-tha-tai, BURM. | Cowa, HIND.

Scarce, but found widely dispersed in the Pegue Forests,—yellow-wood, fit for fancy work.—*McClelland.* This tree is common near water in Kotah and Mewar and attains a very large size: yields a gum resin like gamboge; which however is not collected.—*Gen. Med. Top. page* 199.

(4019) GARCINIA ELLIPTICA. Dr. Griffiths collected specimens of *Garcinia elliptica* with his own hand in the province of Mergui; and yet remained ignorant that the tree produced gamboge, which cannot be distinguished from the best gamboge of commerce.—*Mason.*

(4020) GARCINIA ? GLUTINIFERA.

Panichekai marum, TAM.—*Ainslie.*

This is one of the very few trees admitted into his list that Dr. Wight has not myself seen and verified, and was introduced in the hope that some resident on the Malabar Coast, would favour him with specimens to determine its name and botanical relations.—*Wight.*

(4021) GARCINIA MANGOSTANA, Var.

Soolum poolie, TAM. | Mangosteen, MAL.

Soolum poollie is the Malayalum name of a variety of the Mangosteen; it is however, a very inferior fruit to that of the Eastern islands.—*Ainslie, page* 232. *G. Mangostana* is the most remarkable species, being the far-famed Mangosteen (Mangees, Marsden) of the Malays, reckoned one of the most delicious of all fruits, and not alone of the countries where it is indigenous, but, as Marsden says, "is the pride of the Malay Islands, and perhaps the most delicate fruit in the world." It is a native of the Malayan Peninsula and of the islands to the eastward of the Bay of Bengal, forming trees of considerable size, with a straight trunk and numerous spreading opposite branches forming an elegant conical head. The tree is considered one of the most ornamental in Batavia for gardens, also as affording an agreeable shade. Bontius compares their appearance to that of citron-trees. It is in flower and fruit a great part of the year, according to Roxburgh, but Marsden says "the returns of its seasons are very irregular." So wedded is it to its indigenous soil and climate, that the innumerable attempts made to cultivate it elsewhere have uniformly failed. Dr. Roxburgh says, "For these 35 years past I have laboured in vain to make it grow and be fruitful on the continent of India. The plant has uniformly become sickly when removed to the north or west of the Bay of Bengal, and rarely rises beyond the height of two or three feet before it perishes." The male and female flowers are sometimes on the same, but usually on separate trees. The germ is superior, rounded from 6- to 8-celled, with one ovule in each, attached to the middle of the axis. The ripe berry is spherical, of the size of a pretty large apple, having the surface even, and crowned with the permanent peltate 6- to 8-lobed stigma. The rind is thick, firm, though somewhat spongy, of a dull-crimson colour, sometimes compared to that of the pomegranate. Seeds as far as 8 in number inclosed in a very abundant soft fleshy envelope which is delicately white, forming the edible part of the fruit, described as delicious to the taste and as dissolving away in the mouth. It is also extremely innocent in its nature, as almost any quantity of it may be eaten without detriment, and persons sick of almost any disease are allowed to partake freely of it without inconvenience. The fruit before ripening is slightly acid. The rind is powerfully astringent, and its decoction is employed in dysentery and as a gargle in aphthæ of the mouth. The bark of the trunk and branches is also considered astringent, and said to be employed by the Chinese in dyeing.—*Eng. Cyc.* The Mangosteen has been introduced from Singapore into Bombay, but the fruit has never been brought to any perfection: probably if grafted

on the Brindoa, which is common in the Concan, (and several trees are found in Bombay,) it might be much improved. Dr. Riddell was informed by a friend, that the Mangosteen ripens (and is equal to the Penang fruit) in the Company's spice gardens on the hills near Courtallum.—*Riddell.* From the rind of the fruit Dr. O'Shaughnessy obtained small quantities of fine gamboge.—*O'Shaughnessy, p.* 235.

(4022) GARCINIA PEDUNCULATA (Tikul or Tikoor of Rungpore) is a tree 60 feet high; trees when 7 years old, 20 feet high, 25 inches in circumference. Flowers from January to March. Fruit ripens in hot season.—*O'Shaughnessy, page* 235.

(4023) GARCINIA PICTORIA. A native of the highest parts of Wynaad. Where the soil is a stiff whitish clay, where there is constant moisture from fogs or rain, the tree is tall, attaining the height of sixty feet. Samples of gamboge the produce of this tree have been found superior, while recent, to every other kind, but not so permanent in its effect as that from Siam.—*Rohde, M.S.S.* This gamboge tree, *Garcinia pictoria*, grows, Dr. Wight says, "on the highest parts of Wynaad," but the same tree grows at the foot of the hills in Tavoy, which border on tide waters.—*Mason.*

(4024) GARCINIA PURPUREA. WILD MANGOSTEEN. Nat. Kokum-Brindao.—A very elegant tree, of a conical form, branches drooping, leaves dark green; fruit round and smooth, size of a crab apple, when ripe of a purple colour throughout the inside; and of an agreeable flavour, it is much used at Goa for jellies and syrup, the tree grows to the height of thirty feet and is found in the Concan, and along the Malabar Coast. *Cocum oil*, or butter, is obtained from the seeds of the *Garcinia purpurea* and is used in various parts of India to adulterate ghee or butter. It is said to be exported to England for the purpose of mixing with bears' grease in the manufacture of pomatum. It is a white, or pale greenish yellow, solid oil, brittle, or rather friable, having a faint but not unpleasant smell, melting at about 95 degrees, and when cooled after fusion remaining liquid to 75 degrees.—*Simmonds.*

(4025) GARDENIA (named after Dr. Alexander Garden of Charlestown, South Carolina, a correspondent of Linnæus), a genus of Plants belonging to the natural order *Cinchonaceæ*. It has the calyx usually ribbed, with a tubular truncate limb divided into several lobes or teeth; the corolla funnel-shaped, or approaching salver-shaped, with a tube much larger than the calyx, and a contorted spreading 5-9-parted limb; the anthers 5-9, linear, sessile in the throat; the stigma clavate, bifid, or 2-toothed, with thick erect lobes; the dissepiments of the ovary 2-5, incompletely dividing it into cells; the berry fleshy, crowned with the calyx, with a papery or bony lining, incompletely 2-5-celled; the seeds immersed in fleshy parietal placentæ. The species are armed or unarmed trees or shrubs, with axillary or terminal, usually solitary, white and fragrant flowers.—*Eng. Cyc.* One of the species of Gardenia, is known as Cape Jasmine,—flowers highly scented, readily grown by cuttings, they thrive in any garden soil and only require a moderate share of water to flower abundantly, their colours are pink, white, and pale yellow, most of which are natives of India.—*Riddell.* Dr. Wight gives Gardenia arborea, 576; campanulata, 578; dumetorum, 580; enneandra, 574; gummifera, 576; Gardenia latifolia, 574, 759; longispina, 582; lucida, 575; montana, 577; turgida, 579; uliginosa, 397.

(4026) GARDENIA ARBOREA, is an unarmed tree with ovate-oblong leaves, terminal, almost sessile flowers, usually arranged in threes; the coralla with a filiform tube and a 5-parted limb; the berry drupaceous, smooth, containing a 4-5-valved shell. It is a native of the East Indies. The fruit is eaten by the natives of India. It is one of the most beautiful species of the genus, and deserves a place in every collection. There are about 50 species of *Gardenia*, which all bear elegant sweet-scented flowers. They thrive best in a mixture of loam, peat, and sand. Under the name of Cape Jasmines, double-flowered varieties of *G. florida* and *G. radicans* are extensively cultivated. Their flowers are very fragrant, and the best way of getting them to bloom freely is to set them in a close frame with a gentle bottom heat in the spring. In the winter they may be placed in the greenhouse. They may be increased by cuttings. (Lindley, *Flora Medica*; Don, *Dichlamydeous Plants.*)—*Eng. Cyc.*

(4027) GARDENIA CAMPANULATA, is a shrubby plant with short branches, spiny at the apex, the spines solitary; the leaves lanceolate, smooth, acuminated at both ends; the flowers on short pedicles in terminal and lateral fascicles; the limb of the calyx campanulate, with a short acutely 5-toothed border; the corolla sub-campanulate, 5-lobed; the berry, roundish, ovate. This plant is a shrub 5 to 10 feet in height, and is a native of the East Indies, in the forests of Chittagong. The berry is about the size of a golden pippin apple, and is employed by the natives of India as a cathartic and anthelmintic.—*Eng. Cyc.*

(4028) GARDENIA CORONARIA. This is an indigenous tree in Tenasserim which produces a profusion of flowers that are white in the morning, when they first open out, but which, on exposure to the sun, become quite yellow.—*Mason.*

(4029) GARDENIA DUMETORUM. RETZE. Emetic Nut.

Markarung kai, TAM.	Jonzulkie, PERS.
Mynphul, HIND.	Manga kaia, TEL.
Jowzal Kowsul, ARAB.	Madana, SANS.

This tree produces a nut about the size of a small nutmeg, containing numerous, sweetish tasted, strong smelling seeds. The Vyteans consider it as amongst their best emetics, and prescribe it, for that purpose (pounded seeds and all) to the quantity of a pagoda weight. An infusion of the bark of the root is given in Bowel complaints —*Ains. Mat. Med. page* 88. These nuts are officinal at Lahore, and in the neighbouring mountains where they grow.—*Honigberger, page* 279.

(4030) GARDENIA FLORIDA: CAPE JASMINE.

Gool Chand. HIND. Gundhuraj,

Both double and single varieties are commonly cultivated in gardens at Ajmeer; the foliage is beautiful and the pure white double blossom are elegant and fragrant.—*Genl. Med. Top. p.* 185. Most Tenasserim gardens, as well as many European, and American, are graced with this tasteful shrub. Its pure snowy blossoms, strongly fragrant, Loudon says, smell "like the narcissus;" and they contrast delightfully with the thick deep green foliage in which they are set. —*Mason.*

(4031) GARDENIA FORTUNIANA, is a most fragrant Chinese plant and now common in English gardens, to which it was introduced by the Horticultural Society in 1845.—*Fortune's Tea Districts, p.* 17.

(4032) GARDENIA GUMMIFERA. Gummy Gardenia, grows wild on the Hills in the Kotah jungles, the leaves and unopened blossoms being shrouded at the point in pure fragrant gum resin, said to be one of the sources of the Dikamully resin.—*Genl. Med. Top. p.* 185.

(4033) GARDENIA LATIFOLIA. BROAD-LEAVED GARDENIA. Papura, HIND.

Grows wild in the moist Kotah jungles and is also cultivated in gardens.—*Genl. Med. Top. p.* 185.

(4034) GARDENIA LUCIDA. Furnishes the Cumbee resin.

(4035) GARDENIA RADICANS, CAPE JASMINE. This favourite shrub is well worth all the care it requires, does little good in pots, and should be planted in a well manured flower bed or border which has been drained with sand, they require a soil more approaching to sand than clay and plenty of water; propagated by cuttings in boxes or seed pots during the rains. It is a native of China.—*Riddell.*

(4036) GARDENIA TURGIDA.

Nunjoonda marum, TAM.

Dr. Wight only knows this from small specimens, and is unable to say whether it is a tree or shrub, but believes the former; the wood which is hard and close grained, is useful in cases where small timber will serve.—*Wight.*

(4037) GARI-GOND. A light substance like the decayed cotyledons of a seed, or decayed, soft grains of the pith of wood, very bitter to the taste. The native druggists of India call it a foreign white gum: it is a purge, and given when vision is much obstructed from any cause: one massee with other ingredients is a dose.—*Gen. Med. Top. p.* 136.

(4038) GARLIC, ALLIUM SATIVUM, *Linn.* Bulbus, or Bulb, of the Common Garlic.

Soom, ARAB.	Bawung, JAV.
Kesun, BALI.	Allium, LAT.
Loshun, BENG.	Bavung-pootie, MAL.
Belluly, CAN.	Seer, PERS.
Soodooloonoo, CYNG.	Lasuna, SANS.
Lasun, DUK.	Ajo sativo, SP.
Ail. FR.	Vulla Poondoo, TAM.
Knoblauch, GER.	Velligudda, TEL.
Lussun, GUZ. HIND.	

A perennial plant cultivated for its roots, which consist of pungent acrimonious bulbs, and have a strong offensive smell and flavour. They are employed as a condiment, and as an ingredient in curries, pickles, chutneys, &c.; they are also used in medicine.—*Faulkner.* Garlic is the σκορδον of the Greeks, *Som* of the Arabs, and *Shumim* of Numbers, xi. 12. It has been used as an article of diet and likewise in medicine from very early times. Bulbs clustered, several enveloped in the same silvery skin. Stem about 2 feet high, leafy below the middle. Leaves glaucous, distichous, channelled above, obscurely keeled, acute. Spathe single, calyptiform, horned. Umbels bulbiferous. Flowers, if any, pink, red, or whitish, rather larger than the stamens. (*Lind.*) —Cultivated from early times in the East, and now in all gardens. Its native country unknown. —St. and Ch. 111.—*Royle.* The Garlic, Onion, and Leek are so well known as condiments, that it is unnecessary to dwell long on their properties, which indeed are so similar that it does not seem necessary that more than one of them should be retained in the Pharmacopœias. The Leek has been considered Diuretic and Expectorant: as an article of diet, it is rather indigestible, and apt to cause flatulence. The Onion is possessed of similar properties, but is somewhat more powerful, though less so than the Garlic. In its roasted or boiled state it is occasionally applied as a poultice to suppurating tumours or to sluggish ulcers. The Garlic, when applied externally, will act as a rubefacient; taken internally, it acts as a stimulant, and being absorbed, as an expectorant and diuretic, producing at the same time a disagreeable odour in the breath. It is sometimes employed as an anthelmintic in ascarides.—*Royle.* Garlic is common all over India, and may be grown from the seed or bulbs—the latter method

being most in practice. One of the bulbs is broken and the cloves taken out and planted in beds about four inches apart: no particular care is required, save watering and keeping clear of weeds. When the leaves dry and wither, then take up the roots and preserve in a safe place. —*Riddell.*

(4039) GARLIC OIL—ALLIUM SATIVUM.

Vellay poondoo, TAM. | Lussan-ka-teil, HIND.

A stimulating oil obtained from garlic bulbs by expression. It is prescribed internally by native practitioners to prevent the recurrence of intermittent fevers, and externally in paralytic and rheumatic affections.—*Faulkner, M. E. of* 1855.

(4040) GARNET.

Grenat, FR. | Granati, LAT.
Granaten, Granat-stein, GER. | Granatnoi-kamen, RUS.
Granate, IT. | Granadas, SP.

Garnet, a well-known precious stone, of which there are many varieties. Some of them are probably distinct species; but agreeing in form, and some other properties, they are classed together. This mineral occurs crystallised, massive, and granular. Garnet occurs abundantly in mica-slate, hornblende slate, and gneiss, and less frequently in granite and granular limestone. It is found sometimes in serpentine and lava. The best precious Garnets are from Ceylon and Greenland. *Grossularite* occurs in the Wilin River, Siberia, and at Tellemarken in Norway; green Garnets are found at Swartzenburg Saxony; *Melanite* in the Vesuvian Lavas; *Ouvarovite* at Bissersk in Russia; *Topazolite* at Mussa, Piedmont; *Aplome* in Siberia on the Lena, and at Swartzenburg. Garnets also occur in several parts of the United States. The Garnet is the Carbunculus of the Romans. The Alabandic Carbuncles of Pliny were so-called because they were cut and polished at Alabanda. Hence the name *Almandine.* The clear deep red garnets make a rich gem, and are much used for ornament. Those obtained from Pegu are most valued. They are cut quite thin on account of their deep colour. Cinnamon-stone is also used for the same purposes. Garnet when powdered is used for the same purposes as emery.—*Eng. Cyc.* Precious garnets, or almandins, in the form of pebbles, are often seen for sale among the Burmese; but it is not certain that any are found in the Tenasserim Provinces. Mineralogists say, the most beautiful come from Sirian the capital of Pegu. It is the carbuncle of the ancients. "In a creek on the Siamese side" of the Tenasserim valley, Dr. Helfer says "rubies are found. They are however of a very inferior description"—probably garnets. The common garnet is occasionally seen in the sands of the rivers, but it is not abundant.—*Mason.* At the Madras Exhibition of 1857, Garnets, Carbuncles and Ruby Garnets of very good quality, were exhibited from Nellore, Masulipatam and Bazewarah; but they are not nearly so large, as the Garnets from Mysore and Cuddoor shown at the Exhibition of 1855. The red variety of this gem is very generally diffused over India. Its geognostic position, is the hypogene or metamorphic schists, more particularly near their line of junction with plutonic rocks, or trap dykes; for instance, in the crystalline and metalliferous areas of Salem and Nellore, whence the finest crystals are procured, and sold by the Native merchants at an insignificant price. Colophonite is not uncommon in these tracts, as also in Mysore, the Neilgherries, the Carnatic, and other provinces of Southern India. It usually occurs in the granite, associated with the hypogene schists. That beautiful variety of dodecahedral garnet, called cinnamon-stone or essonite, has been discovered in the Neilgheries in the hypogene hornblende rock, near the Seven Cairns Hill, by Dr. Benza, where their number is such, he informs us, that entire portions of the rock are formed almost exclusively of them. The essonite and hornblende are in large separate crystals, imbedded in a paste of compact felspar and hornblende; the former is very liable to disintegrate, leaving, in falling out, small cavities in the rock. *Green garnet* is of rare occurrence: the only locality where Newbold discovered this gem was in the Salem district at Sankerydroog, lat. 11° 29' N., long 77° 58' E., associated with other green crystals in quartz veins, penetrating hornblende schist. The latter is associated with gneiss, garnet rock actinolitic schist, and altered limestone, thrown into disorder by the intrusion of a porphyritic granite. The green garnet is not found in considerable quantities. A mine of precious garnet occurs at Gharilpit, about eight miles south of Palunshah, in the Hyderabad country, in the detritus of a granitic rock, penetrated by trap dykes, and composed of mica, garnets, kyanite, quartz, and felspar. Dr. Voysey, who gives a description of this mine *July* 18, states that the precious garnets are found at the depth of eight or ten feet in the alluvium at the foot of the rock. The surface of the rock and soil were strewed with garnets in great profusion, but these were generally of a very coarse kind. The garnets when collected are gently pounded, and the bad ones broken: those which survive the blows are reckoned of good quality. In a river near the Munzerabad ghat in Mysore, the natives search for garnets, which are sold at one rupee each. They occur there as deposits from a hill of Mica schist which occurs higher up the river, which Captain R. Robert of the Engineers followed up, at the author's request.—*Madras Museum.* The garnet is classed amongst gems, but only one variety is of value, and inferior kinds are so plentiful, that, in some parts of Germany, they are even employed as a flux in smelting iron. In Southern India they

are almost universally employed by the cutler, the stone-mason, and others, as a substitute for emery, under which name the coarser garnets are sold in the bazaars. Unlike corundum, however, the hardness of which is only inferior to the diamond, and ranks ninth in the scale of hardness, the garnet is only 6·5 to 7·5 in degree. Garnets are of various colors, a circumstance due to the varying proportions and combinations of the three or four silicates of alumina, lime, iron and magnesia, of which they are composed. The precious garnets are of a clear, deep red, and on account of their depth of color are cut by the jeweller quite thin. It is this thin stone which is now termed the carbuncle and it is supposed to be identical with the hyacinth or essonite or hessonite. The varieties of garnet are:—1. Almandine or noble garnet. 2. Grossular garnet. 3. Cinnamon stone, hessonite or kaneel stone; romanzonite; hyacinth. 4. Common lime garnet. 5. Magnesia garnet. 6. Iron garnets. 7. Common iron garnet; rothoffite; alloclorite. 8. Melanite; pyreneite. 9. Colophonite. 10. Uwarorite. 11. Pyrope, almandine, hexahedral garnet. 12. Helvine or tetrahedral garnet. 13. Idocrase or pyramidal garnet. Dr. Voysey states (Asiatic Journal of Bengal, volume 11, para 404) that the precious garnets of Gharliput are found in the alluvium at the foot of the rock, at the depth of eight or ten feet, and that the garnets when collected are gently pounded and the bad ones broken, those which survive the blows being reckoned of good quality; garnets of a very coarse kind were strewed in great profusion over the surface of the rock and soil.—*Madras Museum Report.*

(4041) GARO. Ta-yau, BURM.

A tree that grows in the Moluccas, called *garo*, Linnæus has described as *Excœcaria agallocha*, which the Burmese call *ta-yan*. It is abundant near the sea, the juice is said to produce the most intense pain, and often blindness, if it enters the eye. From its power to produce blindness the Karens call it the "blind tree; and the natives are all of them so much afraid of it, that Mr. Mason has sometimes found it difficult to induce his boatmen to pull up beneath its shade. —*Mason.*

(4042) GARUGA PINNATA. *Terebinthaceæ*, Icon. 1594.

Curry vaimboo marum, TAM. | Kooruk, HIND.

A tree, leaves pinnate, deciduous; flowers of a yellowish white, in panicles covered with a mealy kind of white substance; fruit size of a small plum, used for pickling.—*Riddell.* It is a considerable sized tree with a round umbrageous head. Dr. Wight was not yet acquainted with the wood.—*Wight.*

(4043) GASTEROPODA, the third class of Mollusks, according to the system of Cuvier, who remarks that it is very numerous, and that an idea may be formed of it from the slugs and shell-snails.—*Eng. Cyc. Vol.* II. *page* 924.

(4044) GASTRODIA. The bulb of *Gastrodia sesamoides* (R. Brown), a curious herbaceous species of orchis, native of New Holland, is edible, and preferred by the aborigines to potatoes and other tuberous roots. Some of Mr. Simmond's accredited informants believe it might be turned to profitable account, but being a parasitic plant, it could scarcely be systematically cultivated. It flourishes in its wild state on loamy soil in low or sloping grounds. The first indication of its vegetation in the spring, is the appearance of a whitish bulb above the sward, of an hemispherical shape, and about the size of a small egg. The dusky white covering resembles a fine white net, and within it is a pellucid gelatinous substance. Again within this is a firm kernel, about as large as a Spanish nut, and from this a fine fibrous root descends into the soil. It is known in Van Diemen's Land, and other parts of Australia, by the common name of native bread. Captain Hunter, in his Journal of the Transactions at Port Jackson on the first settlement of the Convict Colony, speaks of finding large quantities of "wild yams," on which the natives fed, but the roots were not bigger than a walnut; therefore it was probably this plant.—*Simmonds.*

(4045) GAVIALIS. The Gavial. Jaws very long, subcylindrical, slender, rather dilated and convex at the end. Teeth, canines two, quite anterior, small; lower canines shutting into a notch in the edge of the upper jaw. Feet fringed; toes webbed to the tip. The cervical plates united to and forming a disc with the dorsal ones. Males with a large swelling in front of the nostrils. Native of Asia.—*Eng. Cyc. p.* 198.

(4046) GAVIALIS GANGETICUS, the Narrow-Beaked Corcodile of the Ganges, Edw., 'Phil. Trans.' Natural. Syst. Amph.; *Gavialis Gangeticus*, Gray, 'Synops Rept.;' the Gavial of the Ganges, Griff., 'Anim. Kingd.' The Gavial of the Ganges is supposed to be the largest of the living Saurians. The measurement of the largest mentioned by Messrs. Duméril and Bibron is given at 5 metres, 40 centimetres (17 feet 8 inches).—*Engl. Cyc. page* 205.

(4047) GEBANG PALM. The *Corypha gebanga*, Blume, is a useful tree, in Java, thousands of boys and girls are employed in fabricating its leaves into baskets and bags: thatch, and broad brimmed hats are made of them; fishing nets and hats are woven from their fibre and ropes manufactured from their stalks.—*Seeman.*

(4048) GECARCINUS (Leach), the name of a genus of Brachyurous Decapod *Crustacea*, known familiarly to the English as Land-Crabs, and to the French by the appellations of Tourlouroux, Crabes Peints or Crabes Violets, some of these terms being applicable not only to different

species, but to the same species at different ages, so that those various names cannot be depended upon as specific designations. The Land-Crabs, or Gecarcinians, inhabit the warm countries of the New and Old World, and Australasia; but as far as observation has hitherto gone, America and its islands seem to be the places where the form is most highly and most numerously developed. Thus much of the habits of the Land-Crabs of the New World. The late Bishop Heber, in his 'Narrative' gives an account of some Land-Crabs in India, living at a great distance from the sea, and obstructed by great obstacles in their passage to it. "The plain of Poonah," writes the bishop, "is very bare of trees, and though there are some gardens immediately around the city, yet as both these and the city itself lie in a small hollow on the banks of the river Moola, they are not sufficiently conspicuous to interrupt the general character of nakedness in the picture, any more than the few young trees and ornamented shrubs with which the bungalows of the cantonment are intermingled. The principal and most pleasing feature is a small insulated hill immediately over the town, with a temple of the goddess Parvati on its summit, and a large tank (which, when I saw it, was nearly dry) at its base. All the grass-land round this tank, and generally through the Deckan, swarms with a small land-crab, which burrows in the ground, and runs with considerable swiftness, even when encumbered with a bundle of food almost as big as itself. This food is grass, or the green stalks of rice, and it is amusing to see them sitting as it were upright, to cut their hay with their sharp pincers, then waddling off with the sheaf to their holes as quickly as their sidelong pace will carry them." Upon this passage Mr. Broderip observes, that when we call to mind the position of Poonah, and read of the neighbouring river and tank, we may feel inclined to ask whether the river or the tank might not be the scene of ovipositing; and, he adds, that it is not improbable that there may be a race of land-crabs appropriated to continental or even insular situations out of reach of the ocean, and that fresh water may be as necessary to their reproduction as sea-water is to the land-crabs of the West Indies. Such a supposition, he thinks, is in unison with the bountiful provisions of nature for the general diffusion of animal life. ('Zool. Journal,' vol. iv.—*Eng. Cyc.*

(4049) GECARCINUS CARNIFEX. This, according to M. Milne-Edwards, is the *Cancer Carnifex* of Herbst; *Ocypode cordata*, *Gecarcinus Carnifex*, and *Cardisoma Carnifex* of Latreille! and he cites also *Gecarcinus hirtipes* of Larmarck, as a synonym, but with a query.—Carapace very much elevated, and its surface very much curved from before backwards, but nearly horizontal transversely: its lateral edges marked by a projecting and elevated line. A small tooth behind the external orbitary angle. Four rows of spines upon the torsi; the lower not numerous. Pincers large on one side. Manus very large. Fingers touching nearly throughout their length. Length, 2 inches (French). (Milne-Edwards). It is found in the neighbourhood of Pondicherry. *Cancer Hydromus* of Herbst, in the opinion of M. Milne-Edwards, is evidently a species approximating closely to the preceding, if indeed it can be distinguished from it.—*Eng. Cyc.*

(4050) GECKOTIDÆ, a natural family of Saurian Reptiles, belonging to Gray's sub-order *Pachyglossa*, and the *Nyctisaura*. The following is a list of the species of Asiatic *Geckotidæ*, with the Localities they inhabit.

Ædura marmorata, the Marbled Ædura. North Australia.
Æ. rhombifer, the Lozenge-Spotted Ædura. West Australia.
Diplodactylus vittatus, the Yellow-Crowned Diplodactyle. Australia.
D. ornatus, the Beautiful Diplodactyle.
D. ocellatus, the Eyed Diplodactyle. West Australia.
D. marmoratus, the Marbled Diplodactyle. Australia.
D. bilineatus, the Two Lined Diplodactyle.
D. lineatus, the Lined Diplodactyle. Cape of Good Hope.
D. Gerhopygus, the Naked Diplodactyle.
Phyllodactylus pulcher, the Phyllodactyle.
P. tuberculatus, the Large-Tubercled Phyllodactyle.
Ptyodactylus Gecko, the Fan-Foot. Egypt.
Uroplates fimbriatus, the Famocantrata. Madagascar.
U. lineatus, the Sharp-Tailed Famocantrata.
Caudiverbera Peruviana, the Caudiverbera. Peru.
Hemidactylus trihedrus, the Triangular-Tubercled Hemidactyle.
H. maculatus, the Spotted Hemidactyle.
H. Brookii, Brooke's Hemidactyle.
H. depressus, the Groove-Tailed Hemidactyle.
H. verruculatus, the Warty Hemidactyle. Shores of the Mediterranean; Egypt.
H. fasciatus, the Banded Hemidactyle.
H. Mabouia, the Brazilian Hemidactyle. Brazil.
H. mercatorius, the Wandering Hemidactyle.
H. frenatus, the Streaked Hemidactyle. Ceylon.
H. Leschenaultii, Leschenault's Hemidactyle. Ceylon.
H. vittatus, the Streaked Cheeked Hemidactyle. Borneo.
H. Bellii, Bell's Hemidactyle.
D. Garnotii, Garnot's Doryure. South Sea Islands.
Platyurus Schneiderianus, the Platyure. Java.
Leiocerus ornatus, the Banded Leiurus. West Africa.
Crossurus caudiverbera, the Crossurus.
Boltalia sublævis, the Boltalia. India.
Peripia Peronii, Peron's Peripa. Mauritius.
Peropus mutilatus, the Peropus. Manilla.
Pheconyx Seychellensis, the Seychelle Gecko. Islands of Seychelles.
Pentadactylus Duvaucelii, Duvaucel's Pendactyle. India: Calcutta.
P. Leachianus, Leach's Gecko.
Gecko verus, the Gecko. India.
G. Reevesii, Reeve's Gecko. China.
G. Chinensis, the Japan Gecko. China and Japan.
G. Monarchus, the Amboyna Gecko. Borneo.
G. Smithii, Dr. A. Smith's Gecko. Prince of Wales' Island.
G. bivittatus, the Double Streaked Gecko.
Amydosaurus lugubris, the Sombre Gecko.
Gehyra oceanica, the Oceanic Gehyra. Islands in the Pacific.

G. Australis, the Swan River Gehyra. Swan River.
Ptychozoon homalocephala, the Fringed Tree-Gecko. Java.
Tarentola Mauriana, the Tarentola. Egypt.
T. Ægyptiaca, the Egyptian Tarentola. Egypt.
T. Delalandii, Laland's Tarentola. Madeira; West Coast of Africa.
T. Bornecnsis, the Bornean Tarentola. Borneo.
Phelsuma Cepedianus, Lacepede's Phelsuma. Mauritius.
Pachydactylus ocellatus, the Eyed Gecko. Cape of Good Hope.
P, maculatus, the Spotted Pachydactyle. South Africa.
P. elegans. the Elegant Pachydactyle, South Africa.
Sphærodactylus sputator, the Banded Sphærodactyle. South America.
S. punctatissimus, the Lined Sphærodactyle. Martinique.
S. fantasticus, the Black-Headed Sphærodactyle. South America.
S. nigropunctatus, the Black-Dotted Sphærodactyle. South America.
S. Richardsonii, Richardson's Sphærodactyle. America.
Naultinus pacificus, the Pacific Naultinus. New Zealand.
N. elegans. the Kakariki. New Zealand.
N. Grayii, the Long-Toed Kakariki. New Zealand
Eublepharis Hardwickii, Hardwick's Eublepharis. Penang, Chittagong.
Goniodactylus Finorensis, Boie's Angular-Toed Lizard. India.
G. alboangularis, the White-Throated Angular-Toed Lizard. South America
G. ocellatus, the Eyed Angular-Toed Lizard. Tobago
Cyrtodactylus, marmoratus, the Marbled Cyrtodactyle. Java. Philippine Islands
C. pulchellus, the Beautiful Cyrtodactyle. Singapore.
Heteronota Kendallii, the Bornean Heteronote Borneo
Phyllurus platurus, White's Phyllure. Australia.
P. Miliusii the Thick-Tailed Phyllure.
P. inermis, the Spineless Phyllure. Australia.
Stenodactylus guttatus, Wilkinson's Stenodactyle. Egypt.

(4051) GELATINE is a substance the production of which is limited to the animal creation. When the skin and membranous tissues of animals are boiled in water, the liquor, on cooling, forms a jelly. The bones, tendons, and ligaments, under a higher temperature, also yield a jelly, similar in appearance and in properties to the former, but less agreeable to the taste. The ordinary sources of gelatine are clippings of hides, hoofs, horns, feet of calves, cows, sheep, pigs, and various membranes. These are carefully cleaned, then subjected to long boiling, and the liquor strained, skimmed, and allowed to gelatinize: the resulting jelly is stiff and tremulous, and is called *size*. Sometimes the sources from which size is obtained are not so pure as the above, the refuse from the skins of horses, cats, dogs, the cuttings from parchment, vellum, and white leather, and sometimes the membranous parts of fish, being admitted into its composition. Size has an intolerably putrid odour, but it may be purified by the careful application of sulphurous acid. This is sometimes done, the size dried in thin layers, and so used as a substitute for isinglass. Without purification, size is cut into slices, dried, and sold as *glue*. *Isinglass* is the purest form of commercial gelatine. The best is prepared from the air-bladders and sounds of three or four species of sturgeon, inhabiting the Black and Caspian Seas, and their tributary streams. These tissues are cleansed, dried, and scraped, forming *leaf isinglass*; or they are twisted into various forms, and called *long* and *short staple*; or folded into packages, called *book-isinglass*. The manufacture is chiefly carried on in Russia, whence commerce receives the best article. The account given by Martius of the preparation of Russian isinglass is as follows: The swimming bladders of the fish are first placed in hot water, carefully deprived of adhering blood, cut open longitudinally, and exposed to the air, with the inner delicate silvery membrane upwards. When dried, this fine membrane is removed by beating and rubbing, and the swimming bladder is then made into different forms An inferior variety, called *ribbon isinglass*, is received from America. Isinglass is cut by machinery into the delicate filaments in which we usually see it sold. It is a colourless, inodorous substance, perfectly soluble in hot water. It is largely consumed as an article of food. The purest and whitest isinglass is required for domestic use, entirely free from unpleasant odour, and dissolving readily and completely in water. It forms a very transparent jelly, and is indispensable in the preparation of blanc-mange, ices, creams, and other delicacies for dessert. Inferior isinglass answers the purpose of fining beer, &c. A solid gelatine in thin plates and strings, has lately been introduced to answer the purpose of isinglass. The best is transparent, and is brought from France; it is prepared from the gelatine of bones by digestion in dilute hydrochloric acid and long boiling in water. It is much cheaper than isinglass, but it is inferior in nutritive power and digestibility, properties which are diminished by long decoction. The same may be said of another substance called *patent opaque gelatine*, which is prepared from the cuttings of skins, and is therefore a kind of glue. Sources from which these substitutes are procured are not the most agreeable; nor is it likely that in the more delicate preparations of the table they will ever take the place of isinglass. Jellies were formerly supposed to be exceedingly nutritive, and especially suitable for invalids; at present medical testimony leads to the opinion that they are less so, and even less digestible than the flesh or muscular part of animals. Isinglass is made in India, and has long been exported thence to China. In most cases it has a very unpleasant fishy odour, which renders it totally unfit for domestic use. Cod sounds, in the dried state, are brought from Scotland, and used as a substitute for foreign isinglass. *Diamond cement*, or white fish-glue, is made of isinglass dissolved in dilute spirits of wine or common gin. The two are mixed in a bottle loosely corked, and gently simmered in a vessel containing boiling water; in about an hour the isinglass will be dissolved, and ready for use. When cold, it should be an

opaque, milk-white, hard jelly: it is remelted by immersion in warm water, but the cork should be at the same time loosened. After a time a little spirit should be added to replace that lost by evaporation. But the best *isinglass glue* is made by first soaking good isinglass in cold water; when swelled, it is to be put into the spirit, and the bottle containing it set in a pipkin of cold water, which may be brought to the boiling point, when the isinglass will melt into a uniform jelly, free from lumps or strings. The addition of a little essential oil diminishes its tendency to become mouldy. *Glue* is a highly useful and important substance, and its manufacture is carried on upon a large scale, as follows: the parings of hides and pelts from the tanners' and furriers' with the refuse materials already enumerated for gelatine, are the substances from which it is extracted in Britain. These are first placed in a lime-pit, and when sufficiently steeped, they are carried in baskets to a stream of water and rinsed, after which they are placed on hurdles to dry. Whatever lime remains adhering to them is converted into chalk by the action of the air; and though lime would be injurious to the after processes, yet the presence of a small portion of chalk is immaterial. The pieces having been thus cleansed, the next process is the extraction of the gelatine from them by boiling. For this purpose they are placed in a widemouthed bag or net, made of rope, and spread open within a large iron caldron. A light framing of iron within the caldron, prevents the bag from sticking to its sides. Water is then added, and gradually brought to the boiling point; as the animal substances sink, fresh quantities are added, the whole being occasionally stirred up and pressed down with poles. The state of the substances is tested by occasionally taking out a portion, and setting it aside to cool: if a clear mass of jelly be produced, the boiling has been sufficient. The mouth of the bag is then closed by means of cords, and the bag is slowly hoisted by machinery until it rests against, or partly coils round a beam immediately over the caldron, which helps to press out the liquid. In this state it is left to drain. Meanwhile the contents of the caldron, if not strong enough for glue, can be further evaporated by continuing to apply heat. The contents of the bag are boiled a second and a third time for making size; and when the solutions are too weak for either glue or size, they are economically used instead of water. The last remaining refuse is sold for manure. Thus, every portion of animal substance is turned to profitable use. The glue in the caldron, when thick enough, is drawn off into a vessel called a *settling-back*, and maintained at a temperature which will keep it liquid. This gives time for the deposition of solid impurities, and for further clarification by the addition of such fining substances as the manufacturer may prefer. The glue is then run off into wooden coolers about six feet long, one foot broad, and two feet deep. Here it becomes a firm jelly, which is cut out by a spade into square cakes, each cake being deposited in a sort of wooden box, open in several slits or divisions to the back. The glue is cut into slices by passing a brass wire, attached to a kind of bow, along the slits. These slices are placed upon nets, (the marks of which are seen on the dry glue,) and stretched in wooden frames, and are thus removed to the glue-maker's field, where they are placed in piles, with proper intervals for the admission of air, each pile being roofed in, as a protection from the weather. The glue is turned two or three times a day, and for this purpose the roof is lifted off the pile, and the uppermost frame placed on the ground. The cakes are turned one by one, and then the second frame is lifted off and placed on the first. The operation is thus repeated until a new pile is formed near the spot where the old one stood, when the roof is replaced. During the drying the glue is more likely to receive injury than at any other period. In very warm weather the cakes are liable to become so soft as to lose all shape and unite with the frames, or they may even melt entirely, and flow away. A thunder-storm sometimes prevents a whole field of glue from hardening; while a thick fog may make it all mouldy. A brisk drying wind may harden it so suddenly as to render it unsightly and unfit for the market. A hard frost, by freezing the water in the glue, may cause it to crack in all directions, rendering re-melting necessary. Thus the manufacture has many vicissitudes to suffer, and can only be profitably and conveniently carried on in temperate and equable weather. The drying, however, is not entirely finished in the open air. When the glue is about three-parts dry, it is removed into lofts, where, in the course of some weeks or months, the hardening is completed. But as the surfaces of the cakes become mouldy and soiled, it is at length necessary to scour them with a scrubbing-brush and hot water, and set them up to drain. They are then finally dried off in a stove-room at an elevated temperature, which, when they are once solid, only serves to harden and improve them. After stove-drying the glue is fit for the market, where it is judged of by its strong dark colour, and freedom from cloudy or black spots when held to the light. The better sorts of glue are transparent, especially the thin cakes of the *Salisbury glue*, which are of a clear amber colour. The best glue swells without melting when immersed in cold water, and renews its former size on drying. The method of softening it for use is to break it into small pieces, soak 24 hours in cold water, and then melt slowly over a fire with frequent stirring. When prepared in this way it cools down into a stiff jelly, which requires only a little warming to fit it for use.

Glue must not be used in a freezing temperature. A strong compound glue is made by infusing common glue in small pieces with isinglass in spirits of wine, just sufficient to cover the mixture. Heat is then cautiously applied, and when melted, powdered chalk is added, making the whole of an opaque white. A strong glue, which will resist water, is also obtained by adding half a pound of common isinglass to two quarts of skimmed milk, and evaporating the mixture to a proper consistence. If gelatine which has been swelled in cold water be immersed in linseed-oil and heated, it dissolves and forms a glue of remarkable tenacity, which, when once dry, perfectly resists damp. Ordinary glue may be thus dissolved, and a small quantity of red lead, in powder, added. It appears from the observations of M. Schattenman, a glue-maker, (Annales de Chimie, 1845,) that fresh glue dries much more readily than glue that has been once or twice melted; and that dry glue steeped in cold water absorbs different quantities of water according to the quality of the glue; and the proportion of water so absorbed may be used as a test of the quality of the glue. It appears that fresh glue contains water of composition, or water more intimately united with the glue than water mixed with it in the process of melting, which admits of being readily disengaged by evaporation. The combined water of dry glue disappears in the course of successive meltings and solidifications to which glue is subjected. Glue in thin plates is usually of better quality than thick ones, even when made with the same kind of gelatine, because the thin plates admit of a more complete drying than the thick. In applying M. Schattenmann's test, dry glue is immersed for 24 hours in water at the temperature of about 60° Fahr. A jelly will thus be formed, the qualities of which will fairly represent those of the glue. For example: the finest ordinary glue, or that made from white bones, absorbs 12 times its weight of water in 24 hours, so that a plate weighing 3 grammes produces 39 of fine elastic jelly. Glue from dark bones absorbs 9 times its weight of water, and produces not quite so fine a jelly. The ordinary glue of Alsace or of Germany, made from animal refuse, absorbs 5 times its weight of water, producing a soft brown jelly, without elasticity and consistence, and falling to pieces when handled. The common glue of Bologne absorbs $3\frac{1}{2}$ times its weight of water. Well dried glue is much less hygrometric than badly made glues, or those made of inferior materials. The latter are liable to putrefaction. The water of composition seems to be injurious to the strength of glue, which increases in proportion to its dryness. *Marine glue* has no gelatine in its composition. It will be noticed in its proper place. Glue or gelatine has lately been applied, with great success, to the formation of moulds for casting. The difficulties attending the use of sand, clay, plaster of Paris, wax, &c. in forming moulds for casting, are very great where the objects to be repeated are complicated in form. About the beginning of the present century the Germans introduced the use of glue for making moulds, which was not employed in this country until about the year 1826, when Mr. Douglas Fox used it to take casts from anatomical preparations, calcareous concretions, vegetable substances, &c.; and in order to give greater elasticity to the moulds so obtained, and to keep them in a fit state for use during a long period, he mixed treacle with the glue: this, however, was found to discolour the surface of all white bodies, and its application being limited by this objection, the plan was abandoned. About the year 1844 attention was again called to this subject by the production in France of a series of casts in imitation of ivory; and about 1846 the Society of Arts, London, offered a prize which was awarded to Mr. Franchi for his specimens of casting in plaster composition in imitation of ivory. At the time the award was made, the nature of the material used by him was not known; but it has since proved to be pure gelatine, and owing to the skilful use of his material some exquisite electrotype casts deposited in the Geological Museum were obtained from objects greatly under-cut. Mr. Franchi has since found that he can obtain from a gelatine mould a cast in gelatine in relief without losing any of the sharpness of the original. This has enabled him to apply objects modelled on flat surfaces to cylindrical bodies, thus saving the labour and expense of modelling. One great advantage of gelatine moulds is, that casts without seams can be taken from them.—*Tomlinson.* The preparation of gelatine in the form of glue, from skins, &c., is well known in India, and described in the Persian works on Materia Medica under the name of ghur-ree-al-jallood, sureshum jild, and suress.—*Royle.*

(4052) GELIDIUM CORNEUM, according to some narrators, enters into the formation of the swallows nests of the Japanese islands.

(4053) GELOXIUM BIFARIUM.

Ilsai-than-bayah, Burm.

Is found in the Rangoon district, it seldom exceeds three feet in girth, and is only fit for house posts. Wood, white colored, adapted to every purpose of house-building.—*McClelland.*

(4054) GEM SAND OF AVA. Gem sand from the neighbourhood of Ava is sometimes one of the Shan articles of merchandize. It consists of small fragments of nearly all the precious stones found in the country, but garnet, beryl, and spinelle are its principal constituents, more especially the last, which seems to constitute more than three fourths of the whole mass. A single handful will contain specimens of every shade,

black, blue, violet, scarlet, rose, orange, amber yellow, wine yellow, brown, and white. Many retain their original crystalline forms, some have the fundamental form of the species, a perfect octahedron ; but many others have some of the secondary forms, among which it is not uncommon to see twin crystals reentering angles, formed by two segments of the tetrahedron truncated on the angles, and joined together by their bases.—*Mason.*

(4055) GENDARUSSA VULGARIS. Syn. Justicia gendarussa, Linn, *Roxb. Fl. Ind.* i. p. 128.

Caroo noochie. TAM.	Jugut mudun, BENG.
Kali shumbli, DUK.	Nela nirganda, SANS.

Common in gardens in India, and supposed by Roxburgh to be a native of the Malay islands. Flowers during the wet season. It is a shrub with dark purple or green smooth shoots, leaves short stalked, lanceolate, obtuse, smooth, with the rib and veins dark purple. Spikes terminal somewhat whorled, leafy at base, flowers reddish purple. Leaves and stalks when rubbed have a strong, rather aromatic odour. After being roasted they are given in chronic rheumatism by the native practitioners. The plant is also said to be emetic.—*O'Shaughnessy, page* 483. This indigenous species of gendarussa is often planted for borders around Tenasserim gardens.—*Mason.* Wight gives Gendarussa Tranquebarensis.

(4056) GENTIANA, a genus of Plants belonging to the natural order *Gentianaceæ*. It has a 4-5-parted calyx. The corolla is variously divided, twisted to the right in æstivation, often with accessory lobes between the principal ones, without depressed glands upon the petals. The filaments equal at the base ; anthers not changing. The stigmas are terminal on the ovary or style. The placentæ united with the endocarp and overspreading the valves of the capsule.—*Eng. Cyc. Vol.* II. *page* 954. Wight gives Gentiana pedicellata, 1328 ; verticellata, 600.

(4057) GENTIANA KURROO. Syn. Pneumonanthe Kurroo, Don. Royle's Illustrations, p. 278. Mussooree, Simla, and other parts of the Himalayas. The roots are used in the north of India, like the gentian.—*O'Shaughnessy, page* 459. Gentiana kurroo, is found in various parts of the Himalayas. It has a stem about 1-flowered, obtuse leaves, the radical long, lanceolate, those on the stems linear. The teeth of the calyx are long and subulate. The corolla is funnel-shaped, with an intense blue spreading 10-lobed limb, the principal lobes of which are ovate and acute, the intermediate ones scale-like teeth. The root is used like Gentian in the north of Italy.—*Eng. Cyc.*

(4058) GENTIANACEÆ, GENTIANWORTS, an extensive order of Plants belonging to the Monopetalous Exogens, and consisting of herbaceous plants, with opposite ribbed leaves, and flowers whose corolla is imbricated ; the stamens alternate with the petals ; the ovary superior, with two cells standing right and left of the axis of growth ; and seeds containing a minute embryo lying in a mass of albumen. They are generally considered to be in the closest alliance with *Scrophulariaceæ*, but it is possible that their resemblance to that order is one of analogy rather than affinity. Along with *Orobanchaceæ* and *Monotropaceæ*, they seem rather to belong to the albuminous group of Exogens, as has already been shown. The flowers of these plants are usually coloured with pure bright yellow, red, or blue, and in many cases they are on this account among the most beautiful of flowers ; but if we have a high development of form and colour in the majority of the species of this order, so we also have in the Guayana and Mexican plants belonging to the genus *Voyra* or *Leiphaimos* the brown leafless habit and low development of *Orobanche*. This order is famous for its bitterness, which seems to pervade all the species. *Gentiana* itself furnishes all the officinal kinds ; but *Erythræa centaurium*, a beautiful wild flower common in many parts of England, is advantageously employed by country people as a substitute : and the root of *Frazera Walteri* has been used as a means of adulterating the bitter Calumba-root. *Cherayta*, from East Indian plants, is remarkable for the pureness of its bitter. The whole plant is pulled up at the time the flowers begin to decay, and dried for use. There are 60 genera and 450 species of this order. This order extends over almost all parts of the world, from the regions of perpetual snow upon the summits of the mountains of Europe, to the hottest sands of South America and India. They however do not appear in the Flora of Melville Island ; and they form part of that of the Straits of Magellan. The most common genus is *Gentiana*, than which few genera display so full a series of colours in the flowers ; red, blue, yellow, and white are all exhibited in it, with many of the intermediate compound tints. For the properties of the genera of this order see CHIRETTA, CICENDIA, CHLORA, MENYANTHES, VILLARSIA, AGATHOTES.—*Eng. Cyc.*

(4059) GENISTA TOMENTOSA, *Henna* (*Lawsonia inermis*), is an important dye-stuff, and the distilled water of the flowers is used as a perfume. The Mahomedan women in Asia use the shoots for dyeing their nails red, and the same practice prevails in Arabia. In these countries the manes and tails of the horses are stained red in the same manner. The *Genista tomentosa* yields red petals used in dyeing, and containing much tannic acid.—*Simmonds.*

(4060) GEODORUM CANDIDUM and GEODORUM PALLIDUM are two terrestrial

species, members of the genus geodorum.—*Mason.* Wight gives also G. dilatatum.

(4061) GESNERIA. GESNERIACEÆ. Showy species of flowering plants mostly with scarlet and orange colored flowers, they thrive well in any light soil, and may be propagated by seed and cuttings.—*Riddell.*

(4062) GHEE, CLARIFIED BUTTER.

Nyee, TAM. and TEL.	Ghee, GUZ. HIND.
Gritthum, SANS.	Roghun, PERS.

In oriental commerce, is clarified butter, made generally from the milk of cows and baffaloes, and is an article of great importance in India, Arabia, and other Eastern countries, where it is used in the same manner as suet and oil are in England, France, &c. It is largely manufactured at Surat, Kurrachee, Jæffrabad, the Persian Gulf, &c.—*Faulkner.*

(4063) GIGARTINA LICHENOIDES. Ceylon moss.—*O'Shaughnessy, p.* 668.

(4064) GIGARTINA TENAX. The Chinese people collect this sea-weed on the coast to a great extent using it in the arts and also for food. Among these the Gigartina tenax is prepared as affording an excellent material for glues and varnishes. It is simply boiled and the transparent glue obtained is brushed upon a porous kind of paper called "shachi" which it renders nearly transparent. It is also used as a size for stiffening silks and gauze, and extensively employed in the manufacture of lanterns and in the preparation of paper for lattices and windows. This and other kinds of fuci are boiled down to a jelly by the islanders on the south and extensively used for food, it is known in commerce under the name of *agaragar.* —*Williams, p.* 275.

(4065) GILIA ACHILLIEFOLIA. POLEMONIACEÆ. These are beautiful annuals and of easy cultivation, may be grown either in the flower garden, or in pots during and after the rains, easily propagated by seed in any light soil. —*Riddell.*

(4066) GINGELLY OR SESAMUM OIL. (BLACK SEEDED VARIETY)—Sesamum orientale.

Nal ennai, TAM.	Meeta-tel, Til-ka-tel, GUZ HIND.
Munchie Noonay, TEL.	Kurit Schuk, PERS.
Meetha Till ka tael, HIND.	
Jiritch, ARAB.	

The oil expressed from the sesamum seed, which is much used by the natives of India as an article of diet and lighting. It will keep many years without becoming rancid, and for all purposes of medicine and pharmacy; when well prepared, is quite equal to the best olive oil. It is supposed that the large quantities of this oil exported from Bombay to England and France, after undergoing certain purifying processes, is returned to India in the shape of sallad, olive, or Lucca oil. Jingelly oil is largely exported from Bombay to England and France.—*Faulkner.*

(4067) GINGELLY SEED, SESAMUM SEED.

Sumsum, ARAB.	Taila, SANS.
Ellu, CAN.	Yellow, TAM.
Teel, Jingelly, GUZ. HIND.	Nowooloo, TEL.
Kunjed, PERS.	

The Sesamum is extensively cultivated in Southern Asia, for the oil expressed from the seed, which are slightly oval, small, tasteless and inodorous. There are two kinds distinguished, *black*, and *white* or *yellow*, which possess the same properties, and in commerce are met with both in a mixed and separate state. Gingelly seed is largely exported from England and France. This oil is perhaps consumed to a greater extent than any other by the Natives of India, and is second only to cocoanut oil in its importance as an article of commerce. It is extensively cultivated throughout the whole of the Madras Presidency, and has been exported as follows.

Gingelly Seed.

Year 1847-48.	Year 1848-49.
Qr. 17,518.....Rs 1 60,134	Qr. 8,594.....Rs. 1,02,723
Year 1849 50.	Year 1850-51.
Cwt. 1,44,125.....Rs. 299,412	Cwt. 2,27,775...Rs. 4,37,155
Year 1851-52.	Year 1852-53.
Cwt. 1,09,414.....Rs. 302,559	Cwt. 2,51,613...Rs. 5,31,634

Gingelly Oil.

Year 1847-48.	Year 1848-49.
Gl. 19,520———Rs. 14,766	Gl. 14,686———Rs. 11,535
Year 1849-50.	Year 1850-51.
Gl. 52,721———Rs 36,294	Gl. 77,262———Rs. 48,605
Year 1851-52.	Year 1852-53
Gl. 46,196———Rs. 26,722.	Gl 72, 607———Rs. 43,608

Of the gingelly seed exported in 1852-53 the United Kingdom received cwt. 12,713—Ceylon, cwt. 590—France, cwt. 2,87,225—Pegue, cwt. 741—Bombay, cwt. 113—Malacca, cwt. 33 and Travancore, cwt. 148. Of the quantity of oil (72,607 gals.) exported in the same year—gals. 42,043 were shipped to the United Kingdom—gals. 2,963 to Ceylon—gals. 4,232 to Mauritius and Bourbon—gals. 19,698 to Pegue—gals. 46 to Bengal—gals. 27 to the French (Indian) ports, and gals. 3,593 to Malacca.—*Mode of preparation.*—The great disparity of color observed in the specimens of this oil is attributed to the mode of preparation. The method sometimes adopted is that of throwing the fresh seeds, without any cleansing process, into the common mill, and expressing in the usual way. The oil thus becomes mixed with a large portion of the coloring matter of the epidermis of the seed, and is neither so pleasant to the eye, nor so agreeable to the taste, as that obtained by first repeatedly washing the seeds in cold water, or by boiling them, for a short time, until the whole of the reddish brown coloring matter is removed, and the seeds have become perfectly white. They are then dried in the sun, and the oil expressed as usual. This process yields 40 to 44 per cent. of a very pale

straw-colored sweet-smelling oil, an excellent substitute for olive oil. *Uses.*—In India, it is chiefly used in cookery, in anointing the person, for making soap, and for burning in lamps. In England, it is chiefly used for the manufacture of soap, and for burning in Table-lamps, for which it is better suited than cocoanut oil, owing to the lower temperature at which it congeals. *Price.*—Value in England (January 1855) £47.10 per ton. In different parts of Madras Presidency the price of this oil varies from Rs. 1 5 0 to Rs. 6 0 0 per maund of 25lbs. In S. Arcot it is procurable at Rs. 27 12 5 per candy. The prices per maund of this oil, at the undermentioned stations, for the quarter ending 31st October 1854, were as follows.

Arcot, ...	Rs.	3	8	0	Madura, ...	Rs.	5	8	3
Bangalore, ...	„	3	7	3	Mangalore, ...	„	4	1	8
Bellary	„	3	2	0	Nagpore, ...	„	1	12	0
Berhampore, ...	„	2	8	0	Palamcotta, ...	„	4	12	0
Cannanore, ...	„	6	0	0	Paulghaut, ...	„	3	7	0
Cuddapah, ...	„	2	13	0	Samulcotta, ...	„	2	10	8
Jaulnah	„	2	6	0	Secunderabad, ..	„	2	3	11
Jubbulpore, ...	„	1	5	0	Trichinopoly, ...	„	4	1	8
Madras, ...	„	3	14	0	Vellore, ...	„	3	14	0
Masulipatam, ...	„	3	0	0	Vizagapatam, ...	„	3	2	0

Second sort Gingelly Oil, erroneously called "Rape," (Kharasanee yelloo), is from the red seeded variety.—This oil which is expressed from a variety of sesamum differs but little from the one abovementioned. In Tanjore, it is procurable at Rupees 3 0 0 per maund. The following particulars concerning the two varieties of plant, yielding this important oil have been furnished by F. Copleston, Esq., Rajahmundry. Two varieties of Sesamum, are cultivated for the sake of the oil. The gingeley seed *par excellence* is the produce of the plant, which is sown in the month of March, after the rice crop, and is irrigated twice, once at sowing, and once afterwards. The seed which is *black*, and is called 1st sort gingeley, from the fact of its yielding the largest percentage of oil, ripens in May, and sells at the rate of Rs. 60 per candy of 500 lbs. The oil obtained from both varieties, sells at the same price, viz. Rs. 2 14 6 to 3 per maund of 25 lbs according to quality. Second sort gingeley is sown in June, and produces a red seed. The plant although a little larger resembles in most respects the former, it has, however, a somewhat longer leaf, and the flower differs a shade or two in color. A candy of 500 lbs. of this seed sells at Rs. 57 8 0. The price of the oil is the same as that of gingeley. This seed has of late been exported to France, in consequence of which the present price is double what it was three years ago.—*M. E of* 1855. It will have been seen that of this small annual plant there are two or three species. Sesamum orientale, the common sort; and S. indicum, a more robust kind, cultivated at a different season, both natives of the East Indies. S. indicum bears a pale purple flower, and S. orientale has a white blossom. It is the latter which is chiefly grown

and the seeds afford the Gingelie oil or suffedtil, already extensively known in commerce in the East. The expressed oil is as clear and sweet as that from almonds, and probably the Behens oil used in varnish, is no other. It is called by the Arabs "Siriteth," and the seed, "bennie" seed, in Africa. S. orientale is grown in the West Indies under the name of "wanglo." It is said to have been first brought to Jamaica by the Jews as an article of food. 1,050 bags of gingelly, teel, or sesame seed, were imported into Liverpool, in 1849, from the East, South America, and Africa, for expressing oil and 3,700 bags in 1850. There are two kinds of seed, light and dark, and it is about the same size as mustard seed, only not round. A hectare of land in Algeria yields 1475 kilogrammes of seed, which, estimated at 50 cents the kilogramme, amounts to 737 francs, whilst the cost of production is only 259 francs, leaving a profit of 478 francs (nearly £20). The oil obtained from this seed is inferior to good olive oil, but is better adapted for the manufacture of soap. This plant is not unlike hemp, but the stalk is cleaner and semitransparent. The flower also is so gaudy, that a field in blossom looks like a bed of florist's flowers, and its aromatic fragrance does not aid to dispel such delusion. It flourishes most upon land which is light and fertile. The fragrance of the oil is perceptibly weaker when obtained from seed produced on wet, tenacious soils. A gallon of seed seems to be the usual quantity sown upon an acre. In Bengal, *S. orientale* is sown during February, and the crop harvested at the end of May; but *S. indicum* is sown on high, dry soil, in the early part of the rains of June, and the harvest occurs in September. About Poonah it is sown in June and harvested in November. In Nepaul two crops are obtained annually; one is sown as a first crop in April and May, and reaped in October and November; the other as an autumn crop, after the upland rise in August and September, and reaped in November and December. In Mysore, after being cut it is stacked for a week, then exposed to the sun for three days, but gathered into heaps at night; and between every two days of such drying, it is kept a day in the heap. By this process, the pods burst and shed their seeds without thrashing. The seeds contain an abundance of oil, which might be substituted for olive oil; it is procured from them in great quantities, in Egypt, India, Kashmir, China, and Japan, where it is used both for cooking and burning. It will keep for many years and not acquire any rancid smell or taste, but in the course of a year or two becomes quite mild, so that when the warm taste of the seed, which is in the oil when first expressed, is worn off, it is used for all the purposes of salad oil. It possesses such qualities as fairly entitle it to introduction into Europe; and if divested of its

mucilage, it might perhaps compete with oil of olives, at least for medicinal purposes, and could be raised in any quantity in the British Indian Presidencies. It is sufficiently free from smell to admit of being made the medium for extracting the perfume of the jasmine, the tuberose, narcissus, camomile, and of the yellow rose. The process is managed by adding one weight of flowers to three weights of oil in a bottle, which being corked is exposed to the rays of the sun for forty days, when the oil is supposed to be sufficiently impregnated for use. This oil, under the name of Gingilie oil, is used in India to adulterate oil of almonds. The flour of the seed, after the oil is expressed, is used in making cakes, and the straw serves for fuel and manure. The oil is much used in Mysore for dressing food, and as a common lamp oil. From 200 to 400 quarters under the name of Niger seed are imported annually into Liverpool for expressing oil. Three varieties of Til are extensively cultivated throughout India, for the sake of the fine oil expressed from their seeds, the white seeded variety, the parti-colored, and the black. It is from the latter that the sesamum or gingeley oil of commerce is obtained. Sesamum seed contains about 45 per cent. of oil. Good samples of the oil were shown at the Great Exhibition from Vizianagram, Ganjam, Hyderabad, Tanjore, the district of Moorshedabad, and Gwalior. The gingelly seed is stated to be worth about £4 per ton in the North Circars. An oil resembling that of sesamum is obtained from the seed of *Guizotea oleifera* and *Abyssinica*, a plant introduced from Abyssinia, and common in Bengal. These, the ram til, or valisaloo seeds, yield about 34 per cent. of oil. The oil is generally used for burning, and is worth locally about 10d. per gallon. Black Til (Verbesena sativa) is known as kutsela or kala til, in the Deccan. It is chiefly cultivated in Mysore and the western districts of Peninsular India, as well as in the Bombay presidency. About 5,000 maunds are exported annually from Calcutta, 3,703 bags were imported into Liverpool in 1851. The price per quarter of eight bushels, in January, 1853, was from 30s. to £2; of teel oil, in tins, weighing 60 to 100 pounds, £2 to £2 4s.—*Simmonds' Comml. Products, page* 535. See SESAMUM.

(4068) GINGER.

The ginger-plant Zinziber officinale, belongs to the very useful natural order, Zinziberaceæ from which turmeric, East India Arrow-root and some other productions, are obtained. Ginger grows and is cultivated in the tropical regions of Asia, America, and Sierra Leone. The stem reaches generally three or four feet in height, and is renewed yearly, while the root which is the part known as ginger, botanically termed a rhizome, is biennial. The roots, or rhizomes, are dug up when about a year old; in Jamaica, this occurs in January or February, and after the stems are withered. They are well washed, freed from dirt, and in some cases, especially with the better kinds, the epidermis or outer coat is stripped off, and hence the division of ginger into white, scraped or uncoated and into black, unscraped or coated. In estimating the quality of ginger, a variety of particulars have to be taken into consideration as whether the rhizomes are coated or uncoated, their form, colour, and consistence. The rhizomes of ginger of good quality have no epidermis, are plump, of a whitish or faint straw-colour, soft and mealy in texture, with a short fracture, exhibiting a reddish, resinous zone round the circumference; the taste should be hot, biting, but aromatic. The rhizomes of ginger of inferior quality are frequently coated with the epidermis, are less full and plump often contracted and shrivelled; of darker colour, being of a brownish-yellow, of harder texture, termed flinty, and more fibrous, while the taste is inferior, and less aromatic. The principal uncoated sorts of ginger, according to Dr. Pereira, are:—

1. *Jamaica ginger*, imported in barrels holding one cwt. each. It is an uncoated, pale sort; and when of fine quality, occurs in large, bold, fleshy races, which cut soft, bright, and pale-coloured. Inferior samples are small in the race, darker-coloured, more or less flinty and shrivelled.

2. *Uncoated Malabar ginger*, new sort of Malabar ginger, Tellicherry ginger; Calicut ginger, Cochin ginger, "a pale uncoated sort imported in chests, casks, or bays, sometimes from Tellicherry, but usually from Calicut or Cochin." It resembles Jamaica ginger, both in external appearance and flavour; but has, externally, more of a brownish or reddish tint, it first appeared in English commerce about the year 1841.

3. *Uncoated Bengal ginger*, scraped Bengal ginger, new sort of Bengal ginger, Calicut sort of Bengal ginger, "imported in chests of about one and a half cwt. It is an uncoated sort, darker than Jamaica ginger; it is not so large as the uncoated Malabar sort, and is harder and darker." The chief coated gingers are:—

1. *Barbadoes ginger*, "imported in bags of about sixty or seventy pounds. It is a coated sort in short, flat races, which are darker coloured than Jamaica ginger, and are covered with a corrugated epidermis."

2. *Malabar ginger*, unscraped Malabar, old sort of Malabar ginger, common Malabar ginger;

Bombay ginger "imported from Bombay in bags or packets. It is a coated, dark, and small sort."

3. *Bengal ginger*, common Bengal ginger, old sort of Bengal ginger "imported in bags. It is a coated or unscraped dark sort, which cuts flinty and brownish, but is plumper and less wormy than common Malabar ginger."

4. *Sierra Leone ginger*, Africa ginger; "imported in casks or bags. It is a coated sort, the races being generally larger, less flat and less plump, than those of the Barbadoes sort, which in other respects they resemble. According to the authority above referred to, the uncoated ginger—viz. the Jamaica, uncoated Malabar, and uncoated Bengal—are assorted for commercial purposes according to their qualities, thus;—

1. Bold, soft, and bright ginger.
2. Smaller, but soft and bright.
3. Flinty and dark.
4. Shrivelled, and only fit for grinding.

The Barbadoes, African, and coated Malabar and Bengal ginger, are usually sold unassorted. Besides the two kinds of ginger above noticed, other descriptions occur. Thus what is called green ginger, is sometimes imported from Jamaica, it consists of soft and juicy rhizomes with buds, and appears to have undergone but little preparation beyond picking and washing. The young shoots put forth every spring by the perennial rhizome are used in the manufacture of the delicious preserved ginger (conditum zingiberis). These shoots are carefully picked, washed, scalded, scraped, peeled, and then preserved in jars with syrup. (Dr. P. Browne). "The finest preserved ginger is imported from Jamaica, usually in jars. Barbadoes preserved ginger is seldom brought over. The China preserved ginger is stringy. It is sometimes imported in the dried state. We have been informed that dried ginger of good quality, soft and mealy, may, by the following process, be converted into excellent preserved ginger: The rhizomes, selected with care are to be immersed for three or four weeks in very weak syrup, scarcely stronger than sugar-and-water, to which a small portion of the carbonate of potash has been added; this addition being made to give them a fresher and greener tint, and also to assist in softening them. As soon as the ginger has become sufficiently soft, it is put up in very strong syrup of white sugar.—*Hassell.* Ginger is cultivated to a small extent, in Tenasserim, and some of the Chinese make a ginger preserve of the green roots, in imitation of that which comes from China.—*Mason.* It grows in all parts of India: it is generally cultivated in gardens, being sown about the commencement of the rains, and taken up in eight or nine months, though sometimes left in the ground for the following year.—*Riddell.* Ginger is sown at the commencement of the rains in beds of about six feet square, and in a rich cultivated soil. The planting consists in dividing part of the green root, which the natives first soak in a mixture of cow-dung and water; it is then planted about two inches deep and about one foot apart; it requires a great deal of water, and to be kept clear of weeds. When the stalks dry, the ginger may be taken up, although it is sometimes left in the ground for a couple of years. It is better for remaining twelve months, and must be watered during the dry season.—*Riddell.* From an examination of the Analysis, made by Dr. Hassell of the gingers sold in London it appears:

1. That out of twenty-one samples of ginger submitted to examination, no less than fifteen, being more than two-thirds of the whole, were found to be adulterated.

2. That the substances detected were various in character, including sago-meal, potato-flour, wheat-flower, ground rice, Cayenne pepper mustard-husks, and turmeric powder,—these occurring in various quantities, but in the majority of cases constituting the principal part of the article.—*Food and its Adulteration, p.* 390. According to Simmonds, ginger is imported chiefly from the East and West Indies. It is also grown in China. In the young state the rhizomes are fleshy and slightly aromatic; and they are then used as preserves, or prepared in syrup; in a more advanced stage the aroma is fully developed, their texture is more woody, and they become fit for ordinary ginger. The inferior sorts, when dried after immersion in hot water form black ginger. The best roots are scraped, washed, and simply dried in the sun with care, and then they receive the name of white ginger. The rhizome contains an acid resin and volatile oil, starch and gum. It is used medicinally as a tonic and carminative, in the form of powder, syrup, and tincture. The root stocks Alpinia racemosa, A. Galanga, and many other plants of the order, have the same aromatic and pungent properties as ginger. The consumption of ginger is about 13,000 or 14,000 cwt. a year. Of 16,004 cwt. imported in 1840, 5,381 came from the British West Indies, 9,727 from the East India Company's possessions and Ceylon, and 896 cwt. from Western Africa. The difference between the black and white ginger of the shops is ascribed by Dr. P. Browne and others to different methods of curing the rhizomes; but this is scarcely sufficient to account for them, and he cannot help suspecting the existence of some difference in the plants themselves. That this really exists is proved by the statements of Rumphius ("Herb. Amb.," lib. 8, cap. xix., p. 156), that there are two varieties of the plant, the white and the red. Moreover Dr. Wight ("Lond. Med. Journal," vol. viii.) says that two sorts are cultivated in Jamaica, viz., the white and the black; and, he adds, "black ginger has the most numerous and largest roots."

The rhizome, called in commerce ginger root; occurs in flattish-branched or loded palmate pieces, called *races*, which do not exceed four inches in length. Several varieties, distinguished by their color and place of growth, are met with. The finest is that brought from Jamaica. A great part of that found in the shops has been washed in whiting and water, under the pretence of preserving it from insects. The dark colored kinds are frequently bleached with chloride of lime. Barbadoes ginger is in shorter flatter races, of a darker color, and covered with a corrugated epidermis. African ginger is in smallish races, which have been partially scraped, and are pale colored. East India ginger is unscraped; its races are dark ash colored externally, and are larger than those of the African ginger. Tellichery ginger is in large plump races, with a remarkable reddish in externally. Jamaica black ginger is not frequently found in the shops. The Malabar dark ginger is in unscraped short pieces, which have a horny appearance internally, and are of a dirty brown color both internally and externally. Ginger is imported in bags weighing about a hundred weight. The Malabar ginger exported from Calicut is the produce of the district of Shernaad, situated in the south of Calicut; a place chiefly inhabited by Moplas, who look upon the ginger cultivation as a most valuable and profitable trade, which in fact it is. The soil of Shernaad is so very luxuriant, and so well suited for the cultivation of ginger, that it is reckoned the best, and in fact the only place in Malabar where ginger grows and thrives to perfection. Gravelly grounds are considered unfit; the same may be said of swampy ones, for whilst the former check the growth of the ginger, the latter tend in a great measure to rot the root; thus the only suitable kind of soil is that which, being red earth, is yet free from gravel, and the soil good and heavy. The cultivation generally commences about the middle of May, after the ground has undergone a thorough process of ploughing, harrowing, &c. At the commencement of the monsoons, beds of ten or twelve feet long by three or four feet wide are formed, and in these beds small holes are dug at three-fourths to one foot apart, which are filled with manure. The roots, hitherto carefully buried under sheds, are dug out, the good ones picked from those which are affected by the moisture, or any other concomitant of a half-year's exclusion from the atmosphere, and the process of clipping them into suitable sizes for planting performed by cutting the ginger into pieces of an inch and a half to two inches long. These are then buried in the holes, which have been previously manured, and the whole of the beds are then covered with a good thick layer of green leaves, which, whilst they serve as manure, also contribute to keep the beds from unnecessary dampness, which might otherwise be occasioned by the heavy falls of rain during the months of June and July. Rain is essentially requisite for the growth of the ginger; it is also however necessary, that the beds be constantly kept from inundation which, if not carefully attended to, the crop is entirely ruined; great precaution is therefore taken in forming drains between the beds, and letting water out, thus preventing a superfluity. On account of the great tendency some kinds of leaves have to breed worms and insects, strict care is observed in the choosing of them, and none but the particular kinds used in manuring ginger are taken in, lest the wrong ones might fetch in worms, which, if once in the beds, no remedy can be resorted to successfully to destroy them; thus they in a very short time ruin the crop. Worms bred from the leaves laid on the soil, though highly destructive, are not so pernicious to ginger cultivation as those which proceed from the effect of the soil. The former kind, whilst they destroy the beds in which they once appear, do not spread themselves to the other beds, be they ever so close, but the latter kind must of *course* be found in almost all the beds, as they do not proceed from accidental causes, but from the nature of the soil. In cases like these, the whole crop is oftentimes ruined, and the cultivators are thereby subjected to heavy losses. Ginger is extensively diffused throughout the Indian isles, it being especially indigenous to the East, and of pretty general use among the natives, who neglect the finer spices. The great and smaller varieties are cultivated, and the subvarieties are distinguished by their brown or white colors. There is no production which has a greater diversity of names. This diversity proves, as usual, the wide diffusion of the plant in its wild state. The ginger of the Indian Archipelago is however inferior in quality to that of Malabar or Bengal. In the cultivation of ginger great improvement may be adopted and expense saved. The garden plough and small harrow should be used. The present mode of preparing the land for this crop in the West Indies, is by first carefully hoeing off all bushes and weeds from the piece intended to plant; the workmen are then placed in a line and, dig forward the land to the full depth of the hoe, cutting the furrow not more than from five to six inches thick. The land is then allowed to pulverise for a short time; you then prepare it for receiving the plants by opening drills with the hoe, from ten to twelve inches apart, and the same in depth, chopping or breaking up any clods that may be in the land. Two or three women follow and drop the plants in the drills, say from nine to ten inches apart. The plants or sets are the small knots or fingers broken off the original root, as not worth the scraping. The plants are then covered in with a portion of the earth bank formed in drilling. It requires great care and attention in keeping them clean from weeds until they attain

sufficient age. It throws out a pedicle or foot stalk in the course of the second or third week, the leaves of which are of similar shape to that of the Guinea-grass. Ginger is a delicate plant, and very liable to rot, particularly if planted in too rich a soil, or where it may be subject to heavy rains. The general average of yield is from 1,500 to 2,000 lbs. per acre in plants, although he has known as much as 3,000 lbs. of ginger cured from an acre of land. The planting season generally commences in Jamaica in February and March, and the crop is got in December and January, when the stalks begin to wither. The ginger is taken from the ground by means of the hoe, each laborer filling a good-sized basket, at the same time breaking off the small knots or knobs for future planting. A good scraper of ginger will give you from 30 to 40 lbs. of ginger per day. It is then laid on barbacues (generally made of boards) to dry. It takes from six to ten days to be properly cured. The average yield in weight is about one-third of what is scraped. When intended for preserving, the roots must be taken up at the end of three or four months, while the fibres are tender and full of sap. The ginger grown in the West Indies is considered superior in quality to that of the East, doubtless because more care is paid to the culture and drying of the root, but it is of less importance to commerce. The quantities imported from these two quarters is however becoming more equal, and Africa is coming into the field as a producer, 1545 casks and packages having arrived from the western coast in 1846. The annual average export of ginger from Barbados, between the years 1740 and 1788, was 4,667 bags; between 1784 and 1786, 6,320 bags; in 1788, 5,562 cwt. were shipped; in 1792, 3,056 bags and barrels. In 1798, so widely was the culture of this root diffused in Jamaica, that 20,933 bags, of one cwt. each, and 8,864 lbs. in casks were shipped. The exports may now be taken on an average at 4,000 cwt.; but, like all the other staple products of the islands, this has fallen off one-half since the emancipation of the negro population. In the three years which preceded the abolition of slavery, 5,719,000 lbs. of ginger were shipped from Jamaica. In the three years ending with 1848, the quantity shipped had decreased 2,612,180 lbs., as will be seen by the following returns:—

GINGER SHIPPED.

	lbs.		lbs.
1830 ...	1,748,800	1846 ...	1,462,000
1831 ...	1,614,640	1847 ...	1,324,480
1832 ...	2,355,560	1848 ...	320,340
	5,719,000		3,106,820

In 1843 there were shipped from Jamaica 3,719 casks and bags; in 1844, 3,692 casks and 1730 bags; in 1845, 3,506 casks, valued at £4 10s. each, and 1,129, bags, valued at £2 each, equal in all to £18,037. From the island of Hayti 8,769 lbs. of ginger were exported in 1835, and 15,509 lbs. in 1836. 39 packages of ginger were shipped from Barbados in 1851. In Maranham and one or two other provinces of Brazil, ginger of an excellent quality is grown, and a good deal is exported. It was very early an article of culture in South America. According to Acosta, it was brought to America by one Francisco de Mendoza, from Malabar, and so rapidly did its cultivation spread, that as far back as 1547, 22,053 cwt. were shipped to Europe. Southey, in his "History of Brazil" (vol. i., p. 320), says, "Ginger had been brought from the island of St. Thomas, and throve so well that in the year 1573, 4,000 arrobas of 25 lbs. each were cured; it was better than what came from India, though the art of drying it was not so well understood. Great use was made of this root in preserves, but it was prohibited, as interfering with the Indian trade in that wretched species of policy which regards immediate revenue as its main object." Ginger was worth in the London market 25s. to 60s. the cwt. in bond; middling and fine qualities, 80s. to 160s. The duty is 5s. per cwt.—Amount of imports of ginger into the United Kingdom, with the quantities entered for home consumption:—

(4069) GINGERBREAD TREE OR DOOM PALM OF EGYPT is the Hyphæne Thebaica, and receives its name from its fruit having the

look and taste of gingerbread. It is stated by Dr. Lindley to produce the Bdellium. Its wood is used for various domestic purposes and its kernel turned into rosaries.—*Seeman.*

(4070) GINGER PRESERVE. Is imported into India solely from China, in cases containing half a dozen of jars each; the capacity of each jar being about five lb.—*Faulkner.*

(4071) GINSENG, GARANTOGNES.

Ginseng, DUT. FR. GER. IT.	Jinseng, SP.
Jansam, CHIN.	Orhota, TART.
Ginsao, PORT.	

Ginseng; in Chinese called *jin-sam*, is the dried root of the *Panax quinquefolia*. It is obtained in Tartary, and also in America, from which latter country some is exported to China. It is considered by the Chinese as a panacea, and no medicine or dose is regarded as complete without this forms an ingredient. All the ginseng growing in Tartary is the property of the emperor, and he sells a quantity yearly to his faithful subjects, who have the privilege to purchase it at its weight in gold! The co-hong were formerly compelled to purchase upwards of $140,000 worth annually, for which sum a few catties were given them. The roots are about the size and length of a man's little finger, and when chewed have a mucilaginous sweetness; and if good, will snap when broken. They should be sound, firm, and free from wormholes. The Chinese consider that which comes from Tartary to be the best, even when they can see no difference. When first brought from America, the profits were 500 or 600 per cent; but afterwards the price declined so much as at times to be hardly worth bringing. When the new tariff was first settled, the Chinese objected to a reduction of the imperial duties, but on a representation being made to H. E. Keying, the imperial commissioner, it was finally agreed by him, that without changing the tariff, the duty on every separate lot should be levied as if it was one fifth first quality, and four fifths second quality. This arrangement reduces the actual duty paid to 10t. 2m. or $14·17 per picul. Ginseng is clarified by being boiled and skinned, which operation renders the root somewhat transparent. Clarified ginseng varies in price from $60 to $100 a pecul; the crude, from $35 to $70 a pecul; five per cent, is allowed for loss in weight on this article, which is taken from the price agreed upon per pecul. In 1837, there were 212,898 lb. imported, at the value of $108,548. In some years there is much more than this amount; the average importation in 1842 and 1843 was 3000 peculs, at the average price of $48 per pecul. The trade is fluctuating and uncertain, and entirely in the hands of the Americans.—*Hon'ble Mr. Morrison.* Mr. Simmonds reports thus: he says that Ginseng as an article of commerce, is confined to our transatlantic neighbours, who have the monopoly of the supply to China. The root of Panax quinquefolium, the American ginseng, is much esteemed by the Chinese, for certain supposed beneficial effects upon the nerves, and for other presumed virtues; but our physicians have not discovered any proofs of its efficacy in Europe. The plant is an herbaceous perennial, growing upon the confines of Tartary and China, near the great wall. It is found wild, flourishing in moist situations, and attains the height of from two to three feet; it is also now produced largely in the northern, middle, and western states of the American union, particularly Virginia, Louisiana, and Pennsylvania, and a considerable trade is carried on with it to China. A variety of the plant was discovered, a few years ago, in the Himalaya mountains, and small quantities have been sent thence to Canton. It is also found growing in Canada. The root is about three or four inches in length, and one inch in thickness. It resembles a small carrot, but not so taper at the end, and is sometimes single, sometimes divided into two branches. The stem is striated, without branches, and of a red color near the root. The leaves, from four to six of which surround the stem where they form sheaths (bracteal), are simply pinnate. The flower stalk is long and green, the inflorescence a simple umbel. The fruit is a berry of a red color, and contains two seeds of the size of mustard seed. The officinal root differs in appearance, according to the country from which it is brought. In Korea and China it is white, corrugated when dry, and covered with a powder resembling starch. In Mandscharia and Dauria it is yellow, smooth and transparent, and when cut resembles amber. The taste of the root is bitter. Crude ginseng now sells in the Canton market at 70 to 80 dollars per picul of 133 lbs., and cured or clarified root at 130 to 140 dollars. The stem of the plant, which is renewed every year, leaves, as it falls off, an impression upon the neck of the root, so that the number of these rings or marks indicates the age of the plant, and the value of the root increases accordingly.—*Simmonds' Comml. Prod. p.* 436. Mr. Williams tells us that Ginseng is found wild in the forests of Liantung and Manchuria, where it is collected by detachments of soldiers and camp followers, specially detailed for this purpose: the regions where it grows are regarded as imperial preserves, and the medicine itself is held as a governmental monopoly. The importation of the American root at Canton does not interfere to a very serious degree with the imperial sales at the north, as the Chinese are fully convinced that their own plant is far superior, and its high price prevents much of it coming south. —*William's Middle Kingdom, p.* 284. In Tenasserim the Chinese shops have the famous ginseng always on hand, but the plant is not cultivated

(4072) GIRAFFA, (Camelopard of Pennant and authors), a genus of Ruminants, with persistent horns common to both sexes, comprising the tallest of the known quadrupeds. *Dr.* J. E. Gray makes this genus the type of the tribe *Giraffina*. Horns covered with a hairy skin with a tuft of hair at the tip. *Giraffa* has the following characters:—Lip not grooved, entirely covered with hair, much produced before the nostril; tongue very extensile; neck very long; body short; hinder legs short; false hoof none, tail elongate, with a tuft of thick hair at the end. *G. camelopardalis*, the Giraffe or Camel-Leopard is the only species. It is the *Cervus Cameloparadulis*, Linn.; *C. Capensis*, Geoff., Ogilby; *Camelopardalis Giraffa*, *a*, Sundevall; *Giraffa Camelopardalis*, Brisson; *Camelopardalis Giraffa*, Gmelin. There is a pale variety, which has the following synonyms:—*Camelopardalis Giraffa*, *B. Æthiopica*, Sundevall; *Camelopardalis Sennaarensis*, Geoff.; *Camelopardalis Æthiopicus*, Ogilby; *Camelopardalis*, Plin.; *Camelo-pardalus*, Jonst.; *Camelus Indicus*, Joust.; Gyraffe, Belon; *Tragus Giraffa*, Klein; Camelopard, Penn.; Kamel paard, Vosmaer; Giraffe—Thevet, Buffon, Levaill., Shaw, Lichtenst.; Giraffe, or Cameleopard, Harris.—*Eng. Cyc.*

(4073) GISEKIA PHARNACIOIDES. Lin.

Manalie keera, TAM. | Esikedunti koora, TEL.
Ainslie, p. 284.

The leaves of this weed are used by the natives in the preparation of dholl.—*Jaffrey.* Wight in Icones No. 1918, gives also Giseckia molluginoides and G. rubella.

(4074) GIVOTIA ROTTLERIFORMIS. EUPHORBIACEÆ.

Bootallie marum, TAM.

Dr. Wight says, it seems curious that this tree, so common in Southern India, has not yet been named in any work of systematic botany. I have not yet learned any thing regarding the timber: one carpenter here (Coimbatore) speaks disparagingly of it, but I do not consider him a trustworthy authority.—*Wight.*

(4375) GLACIERS, a French word received into our language, and which must not be confounded with Glaciere, which has a different signification. The glaciers, as defined by Saussure, are those eternal masses of ice which are formed and remain in the open air in the valleys and on the slopes of lofty mountains. In the Himalayas glaciers have been observed, and all the phenomena presented in Europe have also been found there. Glaciers are chiefly met with in the range to the north of Karakodrum and another group, apparently the largest accumulation of glaciers in the Kuenlen, was found at the environs of Sassar; but both much smaller than the groups near the Diamer to the North West, investigated by Mr. Adolphe Schlagentweit.—*H. and R. Schlagentweit No.* viii. Glaciers in the north-west Himalaya descend to 11,000 feet; but Dr. Hooker could not discover any in these valleys even so low as 14,000 feet, though at this season extensive snow-beds remain unmelted at but little above 10,000 feet. The foot of the stupendous glacier filling the broad head of the Thlonok is certainly not below 14,000 feet; though being continuous with the perpetual snow (or névé) of the summit of Kinchinjunga, it must have 14,000 feet of ice, in perpendicular height, to urge it forwards.—*Hooker Him. Jour. Vol.* II. *page* 57. Dr. Hooker made frequent excursions to the great glacier of Kinchinjhow. Its valley is about four miles long, broad and flat: Chango-khang rears its blue and white cliffs 4,500 feet above its west flank, and throws down avalanches of stones and snow into the valley. Hot springs burst from the ground near some granite rocks on its floor, about 16,000 feet above the sea, and only a mile below the glacier, and the water collects in pools: its temperature is 110°, and in places 116°, or 4° hotter than that of the Yeumtong hot-springs, though 4,000 feet higher and of precisely the same character. A *Barbarea* and some other plants make the neighbourhood of the hot-springs a little oasis, and the large marmot is common, uttering its sharp, chirping squeak.—*Hooker Him. Jour. Vol.* II. *page* 133

(4076) GLAM TREE BARK, from Borneo supposed to be the produce of a species of Artocarpus, furnishes a paper like bark much used in caulking the seams of vessels.—*Royle Fib. Pl page* 341.

(4077) GLAPHYRIA, a genus of Plants belonging to the natural order *Myrtaceæ*. The limb of the calyx is 5-lobed, petals 5, berry 5-celled many seeded; fixed to the axis, 2 rows in each cell. The species are small Indian trees, with alternate minutely-stipitate leaves, and few-flowered axillary peduncles.—*Eng. Cyc.*

(4078) GLAPHYRIA NITIDA is called by the Malays 'the Tree of Long Life,' probably from its maintaining itself at elevations where the other denizens of the forest have ceased to exist. It affords at Bencoolen a substitute for tea, and is known by the name of the Tea Plant. Various species of *Leptospermum* and *Melalena* bear the same name in the Australian colonies.—*Eng. Cyc.*

(4079) GLAPHYRIA SERICEA has lanceolate acuminated leaves. It is a native of Pulo Penang and on the west coast of Sumatra. The calyx, peduncles, bracts, and young leaves are silky; the petals and cells of ovarium 5 or 6 in number.—*Eng. Cyc.*

(4080) GLASS.

Kunnadie, TAM. | Glas, GER.
Ab-gee-neh, ARAB. | Kanch, Guz, HIND.
Sheesheh, PERS. | Vetro, IT.
Addhamoo, TEL. | Vitrum, LAT.
Glass, DUT. | Steklo, RUS.
Vitre, Verre, FR. | Vidrio, SP.

This well-known transparent, brittle body is formed by mixing together siliceous earth with an alkali, and subjecting them to a strong heat. Several varieties of glass are usually distinguished, the differences in them being produced by the proportion of the constituents, the nature of the alkali, the presence of foreign matter, or the process of manufacture.—*Faulkner*. Glass is one of those discoveries which could hardly escape being made by any people who employed furnaces to reduce metallic oxides; for the necessary ingredients must often have been present; and the heat was sufficient. Beckmann has observed, that the discovery of coloured glass must have followed very soon that of making glass itself. It is probable, however, that coloured glass was made previous to colourless glass. For it is difficult to find materials pure enough to make good glass and it would be some time before the original makers would find out the causes of discoloration. The natives of India seem to have been long acquainted with making different ornaments of glass: for instance, armlets and anklets, while rings of glass form a part of their warping reels. Small glass bottles are also made; but mostly of a more or less greenish colour. The green is called *kanch*, and the purer glass, *sisi*. It is probable that the extensive diffusion of oxide of iron in the Indian soil, which may have led to the discovery of iron, has prevented the making both of good glass and of good pottery. That this is not incompatible with a knowledge of the method of making imitation gems, seems proved by the same having been the case in the time of Pliny; who states that great value was set upon glass quite free from colour, which was called crystal. He also mentions artificial hyacinths, sapphires, and all kinds of black glass; and we know that the glasshouses of Alexandria were celebrated among the ancients. One of the simplest processes for making glass is that practised in the district of Behar. The saline efflorescence of the soil, which is an impure carbonate of soda, is collected and thrown into a cistern lined with clay. This is then filled with water, which is afterwards allowed to evaporate. When dry, the bottom of the cistern is found covered with a thick saline crust, the earth which was intermixed having subsided before the salt began to crystallize. This soda makes glass without any addition, as it still contains a sufficient portion of siliceous matter. They make blackish and greenish glass: a bright grass-green is made by the addition of oxide of copper; and a blue glass by the addition of *rung*. In Mysore the process is more elaborate. Powdered white quartz, one part, being mixed with prepared soda, six parts, is filled into a crucible capable of containing 5½ Winchester gallons. About fifty of these crucibles are placed in a furnace, and the fire kept up for five days, when a frit is produced, with which they make a black, green, red, blue, and yellow glass, by means of additions of oxide of copper, of an ore called *Kemudu*, and of a blue substance called *Runga*. What these are continues unascertained. Though the making of glass has made but little advance in India, the natives work up broken English glass even into barometer and thermometer tubes, &c. Glass globes, silvered in the inside, are made and though the mode of effecting this silvering is not mentioned, an amalgam of quicksilver is probably employed, as, on the application of moderate heat, the silvering becomes dissipated. An art similar to this has of late years been discovered in Britain.—*Royle Arts &c, of India, p.* 474. Ainslie tells us that Glass of an inferior quality was made in several parts of the Peninsula of India, particularly in the Mysore country, at Chinapatam and Muteodu, also at Vallatooroo in Tondiman's dominions, which are contiguous to the Tanjore territory. The manufacture however seems to be confined entirely to small phials and women's bracelets. (1) Above the Ghauts, Dr. Buchanan tells us the frit employed for making glass is composed of one part of fat quartz, and six parts of a kind of ill prepared soda (suja cara) (2). To give glass a green tinge, to the frit just mentioned are added a further quantity of prepared Soda, an iron ore called Carin Kulloo, another ore called Kemudu, (3) and a proportion of calcined Copper; all which materials being mixed and put into the crucible, and properly disposed in the furnace, the fire is kept up for nine days and nine nights. To give glass a red tinge, to the frit already mentioned are added an additional proportion of prepared soda and a quantity of the ore called Kemoodu, after which the whole are fused together for fifteen days and fifteen nights. To make blue glass, to the same frit are added a further proportion of soda, calcined copper, a quantity of powdered Carin Kulloo and a blue substance called Runga, which Dr. Buchanan supposes (but is not sure) may be smalis. To give glass a yellow colour Dr. Buchanan tells us that it is enamelled with the melted calces of the metals—Lead, Tin and Zinc. In Tondiman's country where glass rings appear to be made of a superior quality to those of Mysore, the frit is prepared by adding to fine river sand (Kolindoo manil) (Tam.), a very strong solution of an alkaline earth called Over Munnoo, which contains much Soda. This mixture is formed into lumps which are dried and then fused for many hours together to form the frit. In order to make glass a certain quantity of Poongkarum (an impure carbonate of soda) is added to the powdered frit, and the whole fused together for many hours. To give glass a blue tinge the glass makers add the Runga in the manner mentioned in speaking of the blue glass made in Mysore; they also sometimes though rarely add a calx of copper for the

same purpose. To give glass a black tinge, the glass makers add Warroogoo husks, and the iron ore called CarinKulloo which is also called Carpoo Kulloo. Glass bottles were formerly manufactured at Madras, under the scientific direction of Mr. Ryder, the Assay Master—*Ain's Mat.Med. p.*172. India seems to possess no slight advantages for the manufacture of the best qualities of Glass. As is well known the basis of all glass is Silica and Alkali, of which the former in the shape of common sand is to be met with almost every where, the latter is to be had cheaply and in abundance in most parts of Southern India. In the neighbourhood of Madras as well as in many other localities, the secondary materials also, indirectly essential to the manufacture of the best quality of glass, namely the fire clays used in the construction of the furnaces, are abundant and of very superior descriptions. Yet with all these advantages the natives do not appear to have advanced in the manufacture beyond the first and very rudest stages, and although it is one which, if successfully prosecuted, would probably meet with very extended encouragement, the manufacture of the commonest bottles is not yet practised. The chief defects of the native manufacture are the use of too large a quantity of alkali. In fact, in some cases, it is so much in excess that it might be tasted by applying the tongue to the article. The fault now remarked upon is probably connected with, and caused by another, that of the material being melted at too low a temperature and in too small bulk, and these again probably arise from the use of an improper furnace and an unsuitable kind of fuel. The native furnace is usually a rude hole dug in the ground coated with ferruginous clay, which tends to discolour the glass, and the heat is raised by the use of a bellows blast. Hence the temperature is confined to one point of the mass and is insufficiently diffused, while the body of metal under fusion being small, and the dome and sides above ground being thin, the heat is dissipated from them, and never attains body and elevation sufficient to admit of the mass setting and purifying itself, or of its being freed from air bubbles by the addition of the proper proportion of silica. What is required, is the preparation of the glass in larger quantities at a time, and with this view larger and more carefully constructed furnaces, on the reverberating principle, to be heated by coal; after this, that the process should be attended to more scrupulously, and the materials mixed by weight, instead of being thrown together by measure, as is too commonly the case at present. Country glass is usually made of Dhoby's earth a crude carbonate of soda with a mixture of a little potash and lime 60 to 70 parts, and yellowish white sand 30 to 40 parts composed of small fragments of quartz, felspar, iron and a trace of lime. The good bottle glass of Europe is made of

Sand, ...	58	
Sulphate of Soda, ...	29	per cent.
Lime, ...	11½	
Charcoal, ...	1½	

Sulphate of soda only contains 45 per cent of alkali so that 29 parts contain 13, while the carbonate of soda obtained from dhoby's earth, if we may judge from a specimen exhibited in another section, contains between 30 and 40 per cent of alkali, according to which the alkali used by the Natives would be to that employed in Europe in the proportion of 23 to 13.

The substances generally used by the Natives in colouring glass are as follows:—

Iron, which gives green, brown and black shades.
Manganese.....pink, purple, and black.
Copper,.....blue, green, and deep red.
Arsenic,.....white
Chromate of Iron,..... ,, a dull green.

All these materials are used in a very crude state, and the proportions measured in a most imperfect manner.— *Madras Exhibition Jury's Report.* Buchanan in his travels in Mysore gives an account of the manufacture of glass for Bangles (armlets worn by the natives). The glass is very coarse and opaque and much more of it is made than is there wrought into ornaments. Great quantities of it were brought by the *Bangle* makers from the Westward. It was of five colours, black, green, red, blue, and yellow, the first is most in demand. All the materials for making the glass are found in the neighbourhood. In the hot season the Soulie Munnoo or Soda in the form of a white earthy powder is found in several places near this on the surface of sandy fields. For the exclusive privilege of collecting it the glass makers paid 48 *Co.'s Pagodas;* they make it into cakes, the intention of making it into these cakes is probably to free it from earthy matter; but for making glass this is perhaps no advantage as the earth with which it is mixed is chiefly a quartzose sand, these cakes contain at least one half of their bulk of cowdung and from that cause are inflammable, they are prepared for making glass by being burned and of course afford an exceedingly impure alkali. The glass makers furnace there, is rather better than that of Chennapattana, but still it is exceedingly rude. The manufacturers say that when the army of Lord Cornwallis left *Seringapatam* they gathered with much pains a great number of broken bottles which they found where he had encamped, but after the expense of bringing the bottles to Mutsoda they found that their furnace was not sufficiently strong to liquify European glass. The bottles were then reduced to powder and mixed with alkali, but these materials produced only an useless white glass. Such

glass is therefore considered by them as useless as our cast iron, for neither of these substances are in a state upon which the fires of the natives have any effect. The furnaces are constructed on a high terrace which is built against the inside of the town wall and are in form of a dome or like an oven eight feet in diameter and about ten feet high. The oven is not arched but contracted above into a circular opening about 18 inches in diameter, by making the upper row of stones project beyond those below them. At the bottom of the furnace in the side opposite to the town wall is a small opening through which fuel is supplied, the crucibles are oblong and would contain about 5½ Winchester gallons: having been filled with the materials they are lowered down into the furnace by the aperture in the top by which also the workmen descend. They first place a row of the crucibles all round the furnace with their bottoms to the wall and their mouths sloping inwards, in this position they are secured by a bed of clay which covers the crucibles entirely, having only their open mouths exposed; above this row another is placed in a very similar manner and then a third and a fourth. The furnaces vary in size from such as can contain fifty crucibles thus disposed to such as contain twice that number. The fuel consists of small sticks which, having been gathered a year, are quite dry, a quantity having been put in the bottom of the furnace the workmen ascend and some burning coals are thrown upon the fuel by the opening below; the first fuel is added night and day until the time allowed for vitrifying the materials has expired, the fire is then allowed to burn out and the furnace to cool, afterwards the workmen descend and take out the crucibles, which must be broken to get at their contents.—*Buchanan's Mysore, p.* 371, *Vol.* III.

(4081) GLASS BEADS.

Munnie, TAM. | Kanch-ke-munkeh, DUK.
Bootirsacha, MALAY. |

Various coloured glass beads are brought for sale by the Lubbie stone merchants.—*Ainslie.*

(4082) GLAUCIUM PERSICUM. These are very handsome plants, and showy either in borders or patches: they require a moderate good soil, the plants not too near each other, and the seed sown at the end of the rains, they are natives of the South of Europe and Persia. The colours, red, orange, yellow and purple.—*Riddell.*

(4083) GLINUS TRIANTHEMOIDES.

Sharunnay-keeray, TAM.

A procumbent herb with fleshy leaves of a brownish color; used as spinach; a very abundant and troublesome weed.—*Jaffrey.*

(4084) GLOBE AMARANTH. GOMPHRENA.

(4085) GLOBBA CAREYANA. CAREY'S GLOBBA. On shady banks in the Tenasserim Provinces where violets are seen in England, the pretty orange-flowered globba is not uncommon.—*Mason.* Of this genus Wight in Icones gives Globba bulbifera, 2001; Careyana, 2002; marantinoides, 2001; ophioglossa, 2002; and Orixensis, 2002.

(4086) GLOBIOCEPHULUS RISSII. The Yellow Sea affords this species of Cowfish or round headed cachalot, which the Japanese capture, and other species of whales resort to the waters east of Manchuria. Seals have been observed on the coasts of Liantung, but nothing is known of their species or habits.—*William's Middle Kingdom, page* 258.

(4087) GLORIOSA SUPERBA. Lin.

Kartichey poo, TAM. | Cariari, HIND.

Kartichey poo is the Tamil name of the beautiful flower which is known in England by the appellation of the Superb-Lily. The large, flame-coloured, drooping flowers proceed from the upper part of the stalks. It is sometimes met with in our woods, on the Coromandel side of India, but is more common in Malabar and on Ceylon, in which last mentioned country, the bulbous roots are reckoned poisonous. Grows near Kunatcudu in the district of Coimbatore and in abundance a few miles from Trichinopoly.—*Ainslie's Med. Mat. page* 164. Gloriosa Superba grows wild in the Ajmeer hills in the rains.—*Gen. Med. Top. p.* 189. This beautiful lily is a creeper, and blossoms at the commencement of the rains: it is found in the beds of ravines and edges of rivers. The flowers are of a white, yellow and orange colour, the petals long and fringed. It lasts about eight days, undergoing various changes during that time. The root is a strong poison.—*Riddell.* One of the most curious flowers in the Tenasserim country is the gloriosa. "Gloriosa," says Loudon, "on account of the glorious colours of its flowers, and the elegance of their form. This is a splendid and curious genus." The flower, as large as a lily, hangs down, and the petals, stamens and style all turn and grow up like a flower turned inside out. Then to complete the oddity, the leaves prolong their extremities into tendrils, and the plant walks on its toes.—*Mason.*

(4088) GLOXINIA. GESNERACEÆ. These are handsome plants, the flowers of which are bell-shaped, purple, blue and white, they require a good light rich soil, and are propagated by seed, and stripping off the lower branches from the stem, they require to be well supplied with water.—*Riddell.* The varieties found at Madras are G. maculata and G. caulescens. Both succeed very well, if the roots are started into growth at the commencement of the rains. They require a rich soil well drained, G. caulescens propagated by leaves under glass. G. maculata by division of the roots, require treatment simi-

lar to dahlias for the preservation of the roots, they should not be grown in too large pots.—*Jaffrey.*

(4089) GLUE.

Colle, Fr. | Sirrisht, Guz. Hind.
Leim. Ger.

Is extracted from refuse animal substances, such as the parings of hides, hoofs, ears of horses, oxen, calves, and sheep, and used for cementing wood. When good, it is hard, brittle of a semi-transparent and deep brown colour, and free from clouds and spots.—*Faulkner.* Glue, of a superior kind is derived from the waste residue of animal tissues, which have served the operation of tanning at the Government Tannery, Hoonsoor, samples have been received from Ootacamund, prepared by Mr. Brophy, from bones and remnants of animals which have served as food.—*M. E. J. R.* Glue of a tolerably good quality is made by the Chinese from ox-hides, supplies the Chinese, themselves, and furnishes an article for export to India. See Gelatine.

(4090) GLUGA. This is the Broussonetia papyrifera of botanists, popularly called the paper mulberry tree, the same plant from which a kind of paper is made in China and Japan, and clothing in the islands of the Pacific. The Javanese are the only people of the Archipelago who manufacture a paper from the liber or inner bark of this plant, and this is by a process very similar to that by which the ancients manufactured papyrus. The raw material, however, is of a better quality, and the process of manufacturing it far less expensive; for the ordinary Javanese paper, instead of being costly, like the papyrus, is a very cheap commodity. Its colour is that of parchment; it is very tough, and, except that it is liable to be preyed on by insects, owing to the rice-water used in its preparation, it is very durable. The name of the plant, and the vulgar and polite names of the paper, "daluwang" and "dalambang," are all native Javanese words; and it may be concluded that the art of manufacturing paper from the gluga plant is a native one, and of long standing; for the few ancient manuscripts found in Java, and which, belonging as they do, to the times of Hinduism, cannot be of later date than the year 1478, that in which Hinduism was finally subverted. The Gluga is an object both of culture and manufacture, chiefly carried on in the province of Kadiri, once an extensive seat of Hinduism, and the parties conducting them are the Mahommedan priests: in this matter very likely the successors of the Bramins—*Crawfurd Dict. page* 143.

(4091) GLYCINE, SPEC.

Butwausa, Hind.

A very fine and prolific pulse much cultivated in the upper provinces of India, whence it was sent to Dr. Ainslie some years ago from Lucknow. It did not appear to be at all known to the cultivators on the Coromandel coast.—*Ainslie, page* 236.

(4092) GLYCINE SINENSIS.—Takes its name from glykys, sweet, the roots and leaves of most of the species being so. The colour of the flowers, which hang in racemes from the axils of the leaves, are violet, yellow, or purple, grown in any good soil.—*Riddell.* Fortune says, I here met for the first time, the beautiful Glycine sinensis wild on the hills, where it climbs among the hedges and on trees, and its flowering branches hang in graceful festoons by the sides of the narrow roads which lead over the mountains.—*Fortune's Wanderings, page* 66. At another place he says, a little later in the season, that is from the 20th of April to the beginning of May, another race of flowering shrubs and herbaceous plants succeed those I have named. The most conspicuous amongst them are Viburnum macrocephalum and dilatatum, with their large heads of snow-white flowers; Spiræa Reevesiana, and the double variety, which is more beautiful than the original species, Weigela rosea, now well known in Europe, Moutans of various hues of colour; Azaleas, particularly the lovely little "Amæna", Kerria japonica, the lilac and white glycines, roses, Dulytra spectabilis and Primula cortusoides. It will easily be believed that with such a host of Flora's beauties these Chinese gardens must be gay indeed. But perhaps the most beautiful sight of all is the Glycine sinensis, climbing upon and hanging down from other trees. I believe I noticed in my former works the fine effects produced by this climber when in such situations. I again observed numerous examples this spring, and cannot help drawing attention once more to the subject. The fine plant of this species upon the Chiswick garden-wall is much and justly admired; but imagine a plant equally large, or in some instances much larger, attaching itself to a tree, or even a group of trees entwining itself round the stems, running up every branch and weighing down every branchlet; and, in the end of April or beginning of May, covered with flowers, some faint idea may be formed of the fine effects produced by the glycine in its native country.—*A Residence Among the Chi. p.* 242.

(4093) GLYCYRRHIZA, a genus of Plants belonging to the natural order *Fabaceæ*, or *Leguminosæ*, consisting of herbaceous plants with pinnated leaves, small flowers in axillary spikes, and roots running very much in the soil in which they grow. The technical character of the genus is given by De Candolle thus:—"Calyx naked tubular, 5-cleft, bilabiate; the two upper lobes grow together beyond the others. Standard ovate-lanceolate, straight; keel 2-headed or 2-petalled, straight, acute. Stamens diadelphous. Style filiform. Legume ovate or oblong, compressed, 1-celled 1-4-seeded."—*Eng. Cyc.*

(4094) GLYCYRRHIZA GLABRA. (LIQUORICE.)

Jetimadh, HIND.	Meetha lukri, DUK.
Madhuka & Yastimadhuka, SANS.	Us ul soos, ARAB.
	Bikh-meketh, PERS.

A native of the South of Europe, Crete, and Candia, also of Cochin China. Liquorice root is most employed as an adjunct or corrective for other remedies, and it is often used in powder as an envelope for pills.—*O'Shaughnessy, page* 293. *G. glabra*, the common smooth Liquorice, has ovate rather retuse leaflets, somewhat clammy beneath, as well as the branches; stipules wanting; spikes or racemes of flowers pedunculate, shorter than the leaves; flowers, distant; legumes glabrous, 3 or 4-seeded It is a native of the south of Europe from Spain to Tauria, also of China, and is cultivated in France, Italy, Germany, and England for the sake of its roots. The flowers are of a pale blue colour. The name Liquorice, according to Du Theis, is said to be a corruption of the French word 'reglisse,' which is itself a corruption of *Glycyrrhiza*. The roots abound in a saccharine mucilaginous matter, which is slightly bitter, and readily soluble in water. A powder, and the well-known common extract, are prepared from it. The decoction in different forms is a common remedy for coughs.—*Eng. Cyc.*

(4095) GLYCYRRHIZA ECHINATA has oval lanceolate leaflets, mucronate, glabrous; stipules oblong, lanceolate; spikes of flowers, capitate, on very short peduncles; legumes oval, mucronate, 2-seeded, echinated by bristles. It is native of Apulia, on Mount Gardano, and in the northern provinces of China and of Tartary. The whole plant is glutinous to the touch. The root are horizontal, in taste like the Common Liquorice.—*Eng. Cyc.* This is sometimes called Russian Liquorice. It is found in Greece and Southern Russia, extending, it is said, into Tartary and Northern China.—*Sim's* Bot. Mag. 252; *Nees*, 328. Species of Glycyrrhiza no doubt also extend into Affghanistan, whence Liquorice-root *Jeteemadh* is imported into India. These species may, or may not, be distinct from the preceding.—*Royle.*

(4096) GMELINA, an Asiatic genus of Plants named after Gmelin, author of 'Flora Sibirica,' belonging to the Natural-order *Verbenaceæ*, of which only one species was formerly known, but five are described by Dr. Roxburgh, and a sixth (with some doubtful species) noticed by Dr. Wallich, in his 'Indian Catalogue.' The genus is characterised by having a small 4-sometimes 5-toothed calyx, the corolla large, obliquely campanulate, the border irregularly 4-parted, something like those of foxglove in shape, but mostly yellow in colour. Stamens 4, didynamous, with the anthers 2-cleft. Germ superior, 4-celled; cells 1-seeded; attachment sub-superior. Drupe with a nut, from 1- to 4-celled. Embryo erect, without perisperm. All the species of *Gmelina* form shrubs or trees, of which the latter are valued for their timber. They are found in the islands of the Indian Ocean, extending thence into the Malayan and Indian peninsulas. *G. Asiatica* and *G. parvifolia* are common in various parts of India, and *G. arborea* extends from Prome and Martaban even to the Deyra Valley, in 30° N. lat. The leaves of *G. parvifolia* are remarkable for rendering water very mucilaginous, and are employed medicinally in India; but *G. arborea* (Goombar and Koombar of the natives) appears to be the most valuable for its timber, as, besides being spread over a wide extent of territory, it attains great size. Dr. Roxburgh mentions it squaring into logs of from 18 to 24 inches, which are occasionally nearly 30 feet long. The wood resembles teak, the colour being the same; the grain rather closer, but it is somewhat lighter. It seems particularly valuable for situations where it is exposed to both the influence of air and of water. One experiment was made by placing part of an oustside plank in the river Hoogly, a few miles below Calcutta, "a little above low-water mark, exactly where the worms is thought to exert its greatest powers." Dr. Roxburgh states, that "after remaining three years in this situation, though examined from time to time, the piece was cut, with the view of carrying a specimen of it to England; and to my great joy, I found it as sound and every way as perfect throughout as it was when first put into the river." ('Fl. Ind.,' iii. p. 85.) In another experiment this wood remained good for seven years, while teak, similarly placed, required to be replaced after six years. Hence Dr. Roxburgh suggests experiments on and employment of this wood in ship-building.—*Eng. Cyc.*

(4097) GMELINA ARBOREA.

Coommy marum, TAM.	Gumar, or goomber, BEN.
Goomedee chettoo, TEL.	Jugam, Chookur, HIND.
Sewun, DUK.	Kyoonboe, BURM.

A large timber tree, growing in mountainous districts of Southern Asia. Leaves petioled, cordate and pointed; flowers in April and May, large, yellow, tinged with brown. The wood of the tree is used for making the cylinders of drums, &c.—*Riddell.* Wallich met with this tree on the Salwen, but it has never fallen under Mr. Mason's observation, and he is unacquainted with its native name. It produces, however, a useful timber, "not readily attacked by insects."—*Mason.* Dr. McClelland writing on the *Yellow Woods* of Pegu, says, there are three kinds fit for fancy work, and includes *Gmelina arborea*, as plentiful in the Pegu and Tounghoo Forests. It is a large and remarkably strong tough timber. Wood yellow, fit for fancy work.—*McClelland.* It is rather frequent on the Malabar coast. It is the *G. Rheedii* of Hooker in the Botanical magazine.—*Wight.* The wood is light

ale yellow colour, easily worked, and does not or warp, is used for picture frames, deck- mall boats, for making venetian blinds, ing boards, palankeen pannels, gram mea- &c. This tree deserves notice, it is very monly used in the Vizagapatam district, for foundation of walls and other purposes, ch require it to be submerged in water, where it is remarkably durable.—*M. E. J. R.* It is a very large timber tree, the wood of which much resembles teak and is very little affected by worms or the ordinary causes of decay. (*Fl. Ind.* vol. ii. p. 85.)—*O'Shaughnessy, p.* 486.

(4098) GMELINA ASIATICA. VERBENACEÆ, Ill. 174.

Nelacoomul vayr, TAM.	Nelacoomul. ROOT
Goomadoo also Nela Gooma die vayroo, TEL.	Gmelina Asiatica, LIN.
	Biddarie, SANS.

This plant rarely attains the size of a large shrub. It is very common on the Coromandel Coast. The root is mucilaginous and demulcent. —*O'Shaughnessy, p.* 486. Shrub small scolloped leaves and large yellow flowers armed with thorns, and forms an excellent hedge.—*Riddell.* Its root, which is mucilaginous and demulcent, the Vyteans reckon amongst those medicines which purify and sweeten the blood in cases of depraved habit of body.—*Ains. Mat. Med. p.* 94.

(4099) GMELINA PARVIFLORA.

Goomadi, TAM. Sheeri goomoodoo, HIND.

A shrub like the former, having dark orange coloured flowers.—*Jaffrey.* Its leaves slightly bruised under water render it mucilaginous, which property the water retains till the mucilage is decomposed by fermentation.—*O'Shaughnessy.*

(4100) GNAPHALIUM EXIMIUM.—These flowers possess the quality of retaining their colour long after being gathered, the stalk is covered with a whitish down, they are very hardy, both the annual and bienial, the colours are yellow, purple, crimson, yellow and white in North America, Africa and Egypt, and grow from two to three feet in height.—*Riddell.* Wight gives Gnaphalium hypoleucum, 1114; marcescens, 1115; Neilgherryanum, 478.

(4101) GNEMIUM GNETUM.

Bagu, MALAY.	Wagu, JAVANESE.

A coarse cordage is made from the fibrous bark of this tree, which is in extensive use by the people of the Archipelago.—*Crawfurd's Dict. p.* 26.

(4102) GNETACEÆ, *Joint-Firs*, a natural order of Plants belonging to the small class of Gymnosperms. The species consist of small trees very much branched, or of sarmentose shrubs with opposite or clustered branches, and thickened separable articulations. The leaves are opposite, entire, with pinnate veins, sometimes very minute and scale-shaped. The ligneous tissue of the wood is marked with circular discs. The flowers are monœcious or dicœcious; the stamens are contained in a 1-leaved calyx; the ovary is perforated at the apex, containing in a single cavity a solitary erect ovule; the ovule pointed by a style-like process, formed from the membrane of the nucleus; there is no trace of a style or stigma. The species of this family are natives of the temperate parts of Europe, Asia, and South America. *Gnetum* is an inhabitant of the hottest parts of India and Guyana. Some of the species of *Gnetum* are used as food. The seeds of *G. Gnetum* are eaten in Amboyna, and are roasted, boiled, or fried. The green leaves are cooked and eaten like spinach. The inside of the fruit of *G. urens* is lined with stinging hairs: the seeds are, however, eaten; the stem exudes a transparent gum, and when cut across yields a large quantity of transparent water, which is drunk. (Lindley, *Natural System of Botany.*)—*Eng. Cyc.*

(4103) GOAT. In Malay it has two names, Kambing and bebek, the last being oddly enough the name for the domestic duck in Javanese.—*Crawfurd's Dict., page* 143.

(4104) GOBIUS, a genus of Acanthopterygious Osseous Fishes belonging to the family *Gobioidæ*. All the species have two dorsal fins, scaly bodies, and a disc beneath the throat formed by the united ventral fins. By means of this disc they have the power of attaching themselves to rocks.—*Eng. Cyc.*

(4105) GODEPORE. A rather hard, fine, close-grained, heavy Ceylon wood.

(4106) GODETIA ŒNOTHERA. This is a very pretty single petalled white flower, blossoming only in the evening; and towards morning turns to a pink, when it closes and withers. A fresh succession of flowers continues many weeks, even during the hot season. Is propagated by seed, either in pots or beds. The seed may be sown in the rains—soil should be rich.—*Riddell.*

(4107) GOKEROO, PRICKLY FRUITED PEDALIUM.

Khusuke-kibeer, ARAB.	Ananeringie, TAM.
Æknerenchi, CYNG.	Yeanugapulleeroo. TEL.
Gokeroo, DUK. GUZ. HIND.	*Faulkner.*
Ghejasoodumoostra, SANS.	

(4108) GOKHRU, GOKHARA, TRIBULUS TERRESTRIS AND LANUGINOSUS, *Caltrops.* The seed, which is highly mucilaginous, as is also the whole plant, is cooling and demulcent, taken in water as a diluent. Very abundant and troublesome to the naked foot of the natives.—*Gen. Med. Top. p.* 135. Mr. Faulkner says they are prickly capsules, which, when agitated in water, renders it mucilaginous, in which state they are prescribed by native practitoners in dysuria, and gonorrhea. They are the produce of an annual plant growing generally on the Coromandel Coast. They are procurable in most Indian bazars.—*Faulkner.*

(4109) GOLD.

Zehab, Tibr, Arab.	Zir, Pers.
Guld, Dan.	Zloto, Pol.
Goud, Dut.	Oiro, Sp.
Or, Fr.	Oiro, Ouro, Port.
Gold, Ger.	Soloto, Rus.

Oro, It.	Guld, Sw.
Aurum, Rex Metallorum, Lat.	Ponnoo, Tam, Soona, Duk. & Hindoob.
Mas, Mal.	Bungarroo, Tel

Gold is one of the precious metals. It differs remarkably from other metals, with a very few exceptions, in the fact that it is found in nature in its metallic state. It is occasionally found mineralised by tellurium. Native gold is Monometric, and occurs in cubes without cleavage, also in grains, thin laminæ, and masses, sometimes filiform or reticulated. The colour varies in shade, sometimes being a bright yellow, at others almost silvery-white, from the quantity of silver with which it is mixed. It is very ductile and malleable. Hardness 2.5 to 3. Specific gravity 12 to 20, varying according to the metals alloyed with the gold. Native gold usually contains silver, and in very various proportions. The finest native gold from Russia yielded—gold 98.96, silver 0.16, copper 0.35, iron 0.05; specific gravity 19.099. A gold from Marmata afforded only 73.45 per cent. of gold, with 26.48 per cent. of silver; specific gravity, 12.666. This last is in the proportion of 3 of gold and 1 of silver. The following proportions have also been obtained; 3½ to 1, 5 to 1, 6 to 1, 8 to 1; and this is the most common; 12 to 1 also is of frequent occurrence. Copper is often found in alloy with gold, and also Palladium and Rhodium. A Rhodium Gold from Mexico gave the specific gravity 15.5 to 16.8, and contained 34 to 43 per cent. of rhodium. Iron and copper pyrites are often mistaken for gold by those inexperienced in ores. Gold is at once distinguished by being easily cut in slices and flattening under a hammer. The pyrites when pounded are reduced to powder; iron pyrites is too hard to yield at all to a knife, and copper pyrites affords a dull greenish powder. Moreover the pyrites give off sulphur when strongly heated, while gold melts without any such odour. Native Gold is to a large extent obtained from alluvial washings. It is also found disseminated through certain rocks, especially quartz and talcose rocks, and it is often contained in pyrites, constituting the auriferous pyrites; the detritus affording gold-dust has proceeded from some gold-bearing rocks. Gold is widely distributed over the globe. It occurs in Brazil (where formerly a great part of that used was obtained), along the chain of mountains which runs nearly parallel with the coast, especially near Villa Rica and in the province of Minas Geraes; in New Granada, at Antioquia, Choco, and Grion; in Chili; sparingly in Peru and Mexico; in the southern of the United States. In Europe it is most abundant in Hungary, at Konigsberg, Schemnitz and Felsobanya, and in Transylvania, at Kapnik, Vorospatak, and Offenbanya; it occurs also in the sands of the Rhine, the Reuss, and Aar; on the southern slope of the Pennine Alps, from the Simplon and Monte Rosa to the valley of Aosta; in Piedmont; in Spain, formerly worked in Asturias; in the county of Wicklow in Ireland; and in Sweden at Edelfors. In the Ural Mountains there are valuable mines, also in the Cailles Mountains in Little Tibet. There are mines in Africa at Kordofan, between Dar-fur and Abyssinia; also south of Sahara, in the western part of Africa from Senegal to Cape Palmar; also along the coast opposite Madagascar between 22° and 28° S. lat., supposed to have, been the Ophir of the time of Solomon. Other regions in which gold is found are India, Malaca, China, Japan, Formosa, Ceylon, Java, Sumatra, and the Philippines. Until lately nearly all the gold of commerce came from Asiatic Russia and Mexico, but recent discoveries of gold in California and Australia have opened new and vast sources of supply. The particulars of the specie exported by the mail of the 20th January 1857, we subjoin; —Per Peninsular and Oriental Steam Navigation Company's Steamer 'Pera,' 19th Jan., 1857:— Bombay silver, £208,270; Ceylon, gold, £6882; Madras, gold, £1,000; silver, £10,000; Calcutta, silver, £141,175. Total, gold, £7882; silver, £359,445. Closing prices were, Consols for money 93½ ¾ and 93⅝, but for account they remained at 93¾ all day. Exchequer Bills ruled rather firmly, viz., at 2s premium, and East India Bonds under £1000 were also 2s premium. The New Three per Cents, brought 94⅛ ⅜, and the Reduced 93⅞ to 94⅛. We subjoin a statement (prepared by Messrs. Haggard and Pixley) of the export of bullion from London to the undermentioned countries during the six months ending 31st December 1856.

1856.	Gold.	Silver.	Total.	Total of Corresponding period last year.
	£	£	£	£
India (including Ceylon) ...	55,000	4,971,500	5,027,000	5,105,350
China and the Straits	54,980	2,753,300	2,808,200	1,696,910
Cape of Good Hope and Mauritius	9,000	3,500	12,500	5,980
Australia, Van Diemen's Land, and New Zealand	—	—	—	—
Hamburg, Belgium, and Rotterdam	1,970,900	740,700	2,711,600	1,095,660
France, via Boulogne, Calais, and Dunkirk	154,460	94,700	249,100	24,940
Peninsula and Mediterranean, with Constantinople and the Crimea	166,500	4,500	171,100	1,075,798
West Indies	161,600	—	161,600	383,060
Brazils	171,100	—	171,100	77,120
Africa	—	5,000	5,000	3,400
Total	2,744,000	8,573,200	11,317,200	9,402,210

During the entire year the total of specie shipped to the above countries reached £17,806,940, against £14,224,610 in 1855. These amounts do not include the large sums sent from the Mediterranean ports, which comprised during the twelve months £3700 of gold and £2,025,540 silver. Neither do they embrace the extraordinary amounts despatched via Folkestone and Dover

France, of which no accurate records are obtainable. In reporting on the state of the bullion market, they give the subjoined as the latest prices :—Bar gold, 77s 9d per oz. standard ; United States gold coin, 76s 4½d per oz ; bar silver, 5s 2½d per oz. standard ; five-franc pieces, 5s 0⅛d per oz. Gold and silver, but the latter principally, is largely imported into India. In a recent publication it was stated that, within the last five years, twenty-four millions of specie has been absorbed by Calcutta and Bombay alone.

		Bombay.	Bengal.	Total.
1851-52	Rs.	1,65,72,753	2,49,62,184	4,15,35,937
1852-53	„	2,23,05,796	3,49,66,251	5,72,72,047
1853-54	„	1,67,82,200	2,12,90,787	3,80,72,987
1854-55	„	67,87,340	64,08,606	1,31,95,946
1855-56	„	3,71,67,761	5,81,00,445	9,32,68,206
Total	Rs.	9,96,15,850	14,57,29,273	24,53,45,123

The drain towards China is almost as great, and both together cause a withdrawal of some seven millions a year from the currency of Europe. In connection with the above, it may be interesting to many to have the following :—

STATEMENT SHEWING THE AMOUNT OF GOLD

Imported from Calcutta into Madras, from 1st November 1855 to 31st Oct. 1856.				*Exported from Madras to Subordinate Ports, from 1st Nov. 1855 to 31st Oct. 1856.*			
Bullion. 1,63,950	Sovereigns. 2,50,685	Gold Mohurs. 19,885.	Total. 4,34,520.	Bullion. 11,625	Sovereigns. 54,840	Gold Mohurs. 750	Total. 87,215

The following, from the Editor, appeared in the *Madras Athenæum*. Our readers may have had their attention attracted by a paragraph, in our Bangalore news, inserted in our issue of Saturday last, announcing the discovery of a nugget of gold in the vicinity of Chittledroog,—and from the rapid changes of an Indian Society many may not be aware that the Madras Presidency, more than those of Bengal and Bombay, has been surveyed throughout its length and breadth by Buchanan, Voysey, Heyne, Turnbull Christie, Benza, Newbold, and Malcomson, all of whom reported the existence of gold in various parts of the country. There are now also in the Central Museum specimens of the matrix rocks and of the sands in which the gold is found, and specimens of rocks are being received said to be of similar structure to those of the gold tracts of California and Australia. As there may be many travellers or residents in the gold regions of this presidency, disposed to examine the mines and trace the gold to the quartz matrix in which it is found, we content ourselves with indicating the various gold localities. The Committee of 1832 who were appointed by this Government to report on Lieutenant Nicolson's proceedings, mention that— " Nearly the whole of the Province of *Malabar*, except that part immediately along the Coast consists of lofty mountains covered with dense forest or thick jungle. The principle chain more immediately connected with the present subject is formed of the *Koondah* and *Mookoorty* Hills to the south-east of *Calicut*, and *Neilgherries* to the east, and the *Wynaad* mountains to the north-east. These send off numerous lateral ranges between which are deep vallies in most places closely covered with forest. The most extensive of these is that of *Nelamboor* including nearly the whole of the *Ernaad* Talook, bounded on the east by the *Neilgherries*, on the north by *Wynaad*, on the north-west by a lateral range running south from the Ghauts called the *Wawoot* Hills, and on the south by the *Koondah* and *Mookoorty* mountains. From these on all sides innumerable mountain streams descend, and uniting near *Nelamboor*, form the *Beypoor* river, of considerable magnitude, which falls into the sea about eight miles to the southward of *Calicut*. The names of the different streams are particularized in a valuable paper on the gold mines by Mr. Sheffield. In the mountainous district of *Wynaad*, streams in the same manner descend through every valley and unite into large rivers which fall into the *Cavery* in the *Mysore* and *Coimbatore* countries. The whole of the mountains abovementioned seem to be of primitive formation. In the *Nelamboor* valley, so far as the observations of the Committee went, the prevailing rock is Gneiss, a kind of stratified granite. Above this in most places, is a species of clay-iron-stone, which from its softness, enabling it to be cut into the form of bricks for building, received from Dr. Buchanan the name of *Laterite*. It is what Geologists call the overlying rock of the whole country between the Ghauts and the sea to the westward, and many of the smaller hills are entirely formed of it. " When fresh dug it is perfectly sectile, but on exposure to the heat of the sun, and to the weather it becomes of considerable hardness. So far as the gold mines are concerned, it may be considered to be a deposit formed in the lapse of ages, from the gradual disintegration of the immense mountain masses in the neighbourhood ; in which process part of the precious ore may be supposed to have been washed down along with the earthy particles. However this may be, it is certain that gold exists more or less abundantly in the whole of the country on the western side of the Ghauts in every stream which takes its rise from the *Koondah*, *Neilgherry* and *Wynaad* mountains, and in the sands of the sea shore along the whole of *South Malabar*. It is throughout in the form of minute grains. One of the persons examined states that he had once or twice seen a piece as heavy as a gold fanam (about the 1-80th part of an ounce Troy), but in all the specimens examined by the Committee, the portions were infinitely smaller. The mines principally exist in the Ernaad, Wynaad, Neddinganaad, Koormenaad, Calicut, and Shernaad Talooks. Considering the length of time that gold has been regularly

collected in the river sands of nearly the whole of Southern India, it is somewhat surprising that no one has as yet traced the gold to its matrix in the higher lands on which the gold rivers rise. This is the more surprising because both Lieut. Nicolson, who during 1830, and 1831 and 32 was employed, with a body of pioneers, to ascertain the value of the gold mines in Malabar, then distinctly stated that he had traced the source of the gold to its matrix, in the rocks of the Coondah and Mokoorty Hills; in one of his later reports he mentioned that the miners in Malabar generally pursue the veins of quartz, and wash the portions of rock and earth composing them, from a belief that they are most productive. About ten years subsequent to this, the late Capt. Newbold remarked that it is where plutonic rocks come in contact with the primary schists that a greater tendency to metallic and silicious development is observed, and we find he writes that from the Himmalayas to Cape Comorin, in the Malayan Peninsula, Borneo, Sumatra, Assam, the Birman Empire, and in Hungary it is in veins of quartz, ferruginous quartz and their alluvium that we find gold to exist in the greatest abundance. The gold rocks now in the Central Museum show the same fact of quartzoze rocks being the matrix of the gold in Southern India. It is not clear how long these gold deposits have been known to the East India Company: but in 1793, Mr. Duncan, when Governor of Bombay, ordered a minute report to be made to him on the subject of the mines in Malabar, which still continue to be worked very industriously by the Natives of the country. Mr. Sheffield the Collector of that province, afterwards in 1831 made their existence known to Government, when he stated that gold dust weighing 11,449 fanams had been collected in a few of the talooks there: Government subsequently sanctioned Lieut. Nicolson's employment with pioneers to ascertain the value of the mines, and on his reports a committee was appointed on the subject. The authorities above referred to mention that gold is found in all the rivers of the Malabar province, from the stream which falls into the sea at Elatoor about 8 miles north of Calicut, and as far south as the numerous streams flowing through the Paulghaut valley, which at their junction about 15 miles below Paulghautcherry to the great Ponany river, and some of which reach the southern boundary between Cochin and Malabar about one hundred and ten miles to the south east of Calicut. The principal places and streams in Malabar where the gold seekers work their mines are as follows:

Ariabode river in Ernaad.

Aripanaad hill in Ernaad.

Alliporam river in Nedingenaad.

Arliporamboor river, a feeder of the Todakul river.

Arnakyum river disemboguing at Caralondy.

Beypore river.—Native gold is found in the beds of the several branches of this river which flow through the Nelamboor valley, before they all unite above Mambaat Angaddy.

Carampoya or Carambye river rises like the Ponapoya, q. v. with which it unites at Poolliumpara in Wynaad, and their united stream is then called Pamdy-paya, but this, on approaching the Ghauts, again divides into two streams and the main branch called in the Nelamboor valley, the Caramboe, rushes down the Alliumpully cherum.

Carcatode in the Ernaad Talook.

Caralondy or Kadaloondy on the sea beach in the Shernaad Talook.

Coodernapoya river, a feeder of the Beypore river.

Caracoorpoya river, descends from Devalla to the right of the road through the Carcoor pass to join the Poonapoya river, q. v.

Cholyode in Monanaad in Wynaad q. v.

Cacatode perhaps the same as Carcatode q. v.

Coorambal, see Neelamboor.

Catchapoora river in Ernaad.

Capul Mines p. 160 vol. xiv.

Carembat jungle near Carcoor p. 161 vol. xiv.

Cumballa Nullay, one of the Chulamally range close under Nellialum.

Devalla and its vicinity in Wynaad q. v.

Eddakara river in Ernaad p. 160 vol. xiv. M. L. S. Journal.

Goddaloor.

Iroopoonjay river in Calicut Talook lb.

Kanamanna river in Ernaad p. 169.

Karote, „ „ „ „ „

Malapooram river in Koornenaad T.

Mambaat p. 167 vol. xiv. M. L. S. Journal.

Malabar, the matrix of the golden ore is supposed to be in the moutains and hills of Malabar, and even many elevated spots in the valleys of Nelamboor and Mookoorty, and immediate vicinity of Devalla and the Koondah and Neilgherry

mountains whilst that which is found in the beds of rivers and other mountain streams seems to be fortuitously brought down by the monsoon rains.

Nambalacutta, in Wynaad q. v.

Nillialum, in Mopeynaad, see Wynaad.

Nelamboor valley—the mines in that direction are innumerable: the principal ones however are in the thickest part of the jungle immediately under the Wynaad Hills and near the following villages belonging to the Teeroopaad of Nelamboor, viz.

Neelamboor viz. Goodrambat, Kutchapoora.

Moondairy and Maneecote p. 164 vol. xiv.

Park Meetil in Wynaad q. v.

Parparangaddy: the sands on the sea beach between Parparangaddy, Caralondy and Beypoor p. 154 p. 157 vol. xiv.

Pallay Kooth river in Ernaad Talook p. 169.

Pathillypaddom ,, ,, ,, ,,

Poolakottu ,, ,, ,, ,,

Pootoo Piryarate ,, ,, ,, ,,

Poonany in Moopeyanaad, see Wynaad.

Parparangady in the Shernaad Talook to Caraloondy and thence to Beypore—the sea beach between these places.

Poonapoya or Golden river that rises in the Paral Mallah N. E. of Mookoorty and forming part of the main chain of the Neilgherries. See Carampoya. The Poornapoya descends the mountains between Alliam Pullay and the Carcoor Cherrum and long before its formation with the Carrumbye, it receives both the Kellakumpoya and Caracoopoya.

Pooney Hill in Tiroowally Talook p. 169.

Poolyode ,, ,, ,, ,, ,,

Poonoor river in Koormenaad Talook ,,

Pooloowye river in Calicut Talook ,,

Poondaloor river in Nedingenaad Talook.

Teeroowalay or Teermoulay a hill near Mambaat Angady, about 150 feet above the level of the Beypore river, p. 156 and 160 vol. xiv. Teeroowambady division of Polwye, North of the Beypore river is a mountain stream which, descending the Ghauts to the left of the road through the Tambercherry pass, runs through the Tambercherry and Palwye districts and forms a junction with the great Beypore river between Pauroor and Sherwaddu, and opposite to Mapooram, in the Ernaad Talook.

Toodakul river a feeder of the Ponancy q v.

Tirompaddy river in Calicut, p. 169 vol. iv.

Varoor river in Ernaad.

Wynaad, above the Ghauts, gold is found in Parkmeetil, a higher table land, between Manantoddy and Nambollacotta, at a place called Chollyode in Monanaad and Nillialum and Ponany in Moopeyanaad, it is likewise found at Devalla and its immediate vicinity in Namballacotta, p. 156 vol. xiv. An officer of the Bombay Artillery, examined the gold districts in the Dharwar and Belgaum collectorates. Many years ago, the attention of the late Captain Newbold was drawn to that locality, when travelling through Damul, and those interested in the subject will find an account, p. 44 of vol. xi. of the Madras Journal, of the gold that he discovered there, in the bed of a rivulet at Sattoor, a few miles from Dhoni, in the Kupputgode range of Hills near Damul. Also in the sands of the *Hurti rivulet*, in the same range, a few miles to the South of *Gudduk*; and he mentions that gold likewise exists in the Kir talook of the Dharwar Collectorate, near Chick Mulgoond. The gold of the Kupputgode range seems mixed with silver, for he obtained a small button of that metal from the auriferous ore collected in the sands near Dhoni, and he subsequently discovered a grey silver ore in a fragment of quartz that he picked up there. There has not been recorded any account of the products of the washings of Malabar, but in washing the sands of the Kupputgode range, there remains a black sand (menachanite) which Captain Newbold supposed to be probably derived from the decomposition of the dykes of basaltic rock, or the greenstone and hornblende rocks in the vicinity. Further to the west, the same kind of black sand is mixed with the gold found in the bed of the river at the village of *Cananelly*, near Bellary, in the Ceded Districts, specimens of which and of the gold discovered there are now in the Madras Museum. Although it has been reported that gold has been detected in the Cuddapah Collectorate, we do not find any sufficient authority for the statement, and think it unlikely to have escaped the notice of Dr. Voysey, who mentions the fact of a large proportion of silver being found in the Sulphuret of Lead discovered 15 miles in a N. E. direction from the branch of the Penaar, South of Cuddapah. The only other places, therefore, in the Ceded districts, where gold is authoritatively mentioned as occurring, is at *Suttangul*, where Heynes at p. 342 of his Tracts describes it as having been discovered near Royacottah, not far from Pangampillay, near Hurrydroog. Although there seems no doubt that the gold in these auriferous rivulets is only washed down from their neighbouring hills, there has hitherto been no effort made in this country to trace the valuable ore to its matrix. Many years ago Captain Newbold suggested that the sands should be carefully examined every 40 or 50 yards, and the spot where the particles of gold no longer appear, most diligently explored, the subjacent rock laid bare, and if necessary an excavation made into it, but with our more perfect knowledge of the matrix of the ore, we would suggest that the explorer, hammer in hand, strike at once at the veins of quartz that traverse the rocks adjacent to the gold rivers, for we are not without hopes that the auriferous quartzes of these province would prove as productive as any in the world. In *the Hyderabad* Territories gold has

been mentioned as occurring at Goodaloor, or Godalore, on the Godavery, where the late Dr. Walker, at p. 184 of vol. xvi. of the M. Literary Society's Journal, mentions its occurrence, where the Ramghere and Cummumet Circars meet, and also in several nullahs that feed the Godavery from the south. Further north, in the Rajah of Berar's territories, Mr. Burr describes gold as occurring in many of the rivers in the Nagpore district, almost in the centre of India, and, at the same page, he gives the late Mr. Mason as his authority for stating that the natives obtain a little gold by washing in the streams near Vizagapatam. As we turn southwards, however, we do not observe mention made of any gold in the Masulipatam or Guntoor Collectorates, nor do the specimens of rocks from these districts in the Central Museum indicate the presence of the ore, there. In the Nellore Collectorate, however, we find Dr. Voysey mentions the occurrence of Copper in the veins of white quartz,—and at Callastry in the North Arcot Collectorate, he states that the quartz rock contains lead ore mixed with silver. As we proceed still more to the south, we enter again upon the gold districts of Madras Presidency; for gold, writes Mr. Burr, is well known to occur in *Coimbatore* and the southern declivities of the Neilgherry Hills. Capt. Newbold states, (vol. I. p. 514 of Sir Whitelaw Ainslie's Materia Medica) that gold was discovered by the late Mr. Mainwaring in the *Madura* district, where it occurs mineralized by means of zinc, constituting a blende which he thought resembled somewhat the Schemnitz blende of Hungary. The streams running through the Paulghaut valley, which unite about 15 miles below Palghautcherry and form the great Ponany river, are repeatedly mentioned as containing gold; and in June 1832 when Lieut. Nicolson was returning to the scene of his mining labours in Malabar, he visited, in his route, such spots as he considered likely to produce the mineral of which he had been in search so many months; and tidings of the existence of the ore are stated to have been found at *Darampooray*, at the foot of the *Shevaroy Hills*, at *Sattiamungalum*, *Donagancottah*, *Addivarum* or *Stremogoy* and *Metapollum*, and a very precise and scientific enquirer, lately arrived in Madras, has now in his possession the gold sands of Polygonuth, about 45 miles from Dindigul, and mentions that he has lately seen the natives washing for gold at the branch of the Cauvery, which runs past Darampooram. When describing the gold of the Kuppotgode range, Captain Newbold mentions the existence of the ore around the base of the Neilgherry and Koondah mountains, and in the Wynaad. Lieut. Nicolson, indeed, when working in Malabar 20 years ago, stated that he had fairly traced the strata that contain gold in the direction of the Koondah and Mookoorty Hills, but this report of his was subsequently found not to rest on solid data; the gold Commissioners attributing the error that that officer had fallen into, to his too sanguine disposition leading him to trust to the report of a native. We have noticed above, however, the existence of gold in the Carcoor Pass, and at Devalla: indeed specimens of the rocks, from the gold mines at the latter place, are now in the Madras Central Museum, and a gentleman of Madras lately brought with him a specimen of the gold rocks at Goondaloor, and Mr. Burr also, at p. 72 vol. xii. of M. J. S. J., mentions the southern declivities of the Neilgherry mountains as gold districts: Dr. Benza is however the only author we have met with, who states that gold has been found on the plateau of these Hills. "It is, he writes, in this kind of magnetic iron ore, particularly in the blocks below Gradation Hall, that I remarked on the quartz laminæ, small, brilliant, gold-coloured specks, precisely similar to those seen in the auriferous quartz veins in the rocks of the Malabar coast, specimens of which have been deposited by Colonel Cullen in the Museum of the Asiatic Society of Bengal. Does this appearance indicate the existence of gold particles in this ore? We know that in America, gold is occasionally found in the siderocriste, which is a species of quartz iron ore, like the one just described. It is the belief of some people, that owing to the similarity of the rocks, of the detritus, and of the quartz veins of the Malabar coast, and of these hills, gold may be found in the last, as well as in the former. The specimen of the earth I send is taken (No. 22) from an excavation made, some years ago, by an officer, who had been employed on the Malabar coast, for the purpose of ascertaining the existence of gold in the detritus of that coast. It is said that he found gold in the earth dug upon the side of one of the hills of the Dodabetta group, facing the cantonment." The quartzoze rock which Dr. Benza says contains the ore is now in the Madras Museum. We now come to the Mysore territories, the only portion of this Presidency requiring to be noticed, and we would particularly direct the attention of enquirers to the various localities in it that we may here point out, as well because of the long known general diffusion there of the precious ore, as because those who have most attentively examined the geology of the Mysore country regard its rocks as strongly indicative of gold being in abundance there. It is not known how long the natives have been working for gold at Baitmungalum just above the Ghats—but Heyne mentions that Captain Warren had learned the fact of the natives employing themselves, in their leisure, in working for the ore amongst the rocks and stones at that place and the same fact is repeated by Sir Whitelaw Ainslie and Dr. Clark, the latter of

whom remarks that gold was discovered in the eastern provinces of Mysore by Lieutenant Warren of H. M. 33d Regiment in 1802,—who found it in the small nullahs or ruts or breaks in the ground at Warrigum, a small village 4½ miles S. W. of Baitmungalum, also on the banks of the Palar river, and the Ponian near Caargory: from a load of earth near the last he obtained 3 sparkles of gold. He found gold also at *Marcoopium* 3 miles south of Warrigum, where there were mines worked by natives and which had also been worked by Tippoo. Heyne likewise (at page 41) states that gold has been found near the hills to the S. E. of Ooscottah, and Newbold describes gold as having been discovered by Captain Warren, near the Batterine Hills. These sites in Mysore we think might all be carefully examined, and the river ore traced to its matrix; the climate is less prejudicial to health than most of the other gold districts that we indicated above; and the reported recent discovery of a nugget may likewise contribute to stimulate to new sites. But we would more particularly request attention to the glacis-like slope at the foot of the Mysore hill facing the town, where a crumbling grey chlorite rock exists, as one that might be looked at. On the right hand side of the Mercara road, about two miles west of the town of Hoonsoor a whitish sand will be observed, which, if washed, gold may be detected in; and it might be looked for also between Yeddadora and Saligram, about 18 miles from Hoonsoor. The specimens now in the Central Museum of rocks from the gold districts of the Madras Presidency, consist of steatite and ferruginous quartz; and such rocks are abundant in Mysore and Madura. Indeed among the steatite and quartz specimens which the Rev. Mr. Muzzy contributed from the Madura district, there are several which closely resemble the specimens from the gold mines at Devalla and other places on the Western Coast. India has not much to boast of with regard to this metal; very little of it having hitherto been found in these provinces. Captain Hardwicke says, it can be obtained from sand, in the Sirinagur country, and we know it to be a product of Assam. (2) Captain Warren discovered a gold mine in Mysore in 1800, betwixt Annicul and Poonganore, but which does not appear to have been much attended to. The metal as far as I can learn, is disseminated in quartz, and also found in the alluvial soil. Gold too, I understand, was obtained in the Madura district, by the late Mr. W. Mainwaring, in a native sulphuret of Zinc (blende). Captain Arthur of the Corps of Engineers informed him that he found Native Gold in Mysore, disseminated in quartz, and also in an indurated clay: some specimens he observed crystallized, in minute cubes. Gold dust has been got in the bed of the Godavery, and in Malabar, in the bed of the river which passes Nelambur in the Ernaad district; it has moreover, been procured in very small quantities, in Wynaad, and in the sand of the Beypoor river, near Calicut. Though the sources are evidently numerous from which this valuable metal can be obtained in the Indian Peninsula, it would seem, from the little interest they have hitherto excited, that none of them promised to be very productive. In other Eastern territories, however, gold is met with in greater abundance. By Forest's account there is much of it in the island of Mindano: it is a produce of almost all the Philippine islands; also of Borneo, of Sumatra, of Pegu, of China, of the Burmah dominions, of Siam and of Thibet; but perhaps, in no part of the world, is it found in such quantity or with less trouble than in Cochin China; nay, it would appear, from the description of that kingdom which may be seen in the Asiatic Annual Register for 1801, that Gold there is almost taken pure from the mines, which are near the surface of the earth.—*Ainslie's Mat. Med. page* 54. Appended to a Memoir will be found accounts of the auriferous deposits ot Assam and the vicinity of Shew Gween in the Province of Martaban. The gold discovered in both localities is of considerable purity, the latter Mr. Oldham considers fully equal in value to the average quality of Australian gold. Though not quite so abundant as in California, yet there is perhaps, no mineral, except iron, more universally diffused over the Provinces, than gold. It is found in the lead near their northern boundary, it is washed from the sands of the Tenasserim on the south, and the streams that tumble from the high granite mountains between Yay and Monmagon, are constantly 'rolling down their golden sands' into the valleys around. It has been collected, in small quantities, in the tin deposits east of Tavoy. Mr. O'Riley found gold in the tin from Henzai, half a degree south of Yai, and "almost all the creeks," says Dr. Helfer, "coming from the eastern or Siamese side of the Tenasserim river, contain gold. The greatest quantity is obtained close to the old town of Tenasserim where people wash it, and obtain sometimes one anna's weight each, during the rainy season." The richest deposit of gold in the Provinces, is however, at the head waters of Tavoy river, where it is found in an alluvial or diluvial formation of red earth and pebbles, very similar to that in which gold is found in North Carolina. On the east side of the mountains, at the base of which this deposit rests, "the Siamese Government," says Dr. Morton, "have several hundred men permanently occupied, each of whom it is said, is expected to deliver one tickal (about one rupee and a quarter) weight of gold dust per annum,—The Burmese authorities in former times also employed people in this work at the streams on our side of the boundary, but

though the quantity then procured was greater than at present, this does not appear to have ever been considerable. The method adopted is that of digging a longitudinal excavation in the sand, and washing, from time to time the deposit found therein." Three or four years ago, the head native officer in Tavoy made an experiment at "the diggings" on Tavoy river, and by the washings, of nine days, obtained gold to the value of about ten rupees. This gold appears to contain a considerable proportion of silver. Mr. O'Riley says that the Assay Master at the Mint in Calcutta reported it.

Gold,.....	87.895
Silver,.....	9.241
Base metal,.....	2.864
	1,00,000

This metal, in sufficient abundance to be worked, is found in the Malay Peninsula, Sumatra, the Western and Southern sides of Borneo, the Northern and South-Western Peninsulas of Celebes, and in a few parts of the great Philippine islands of Luzon and Mindano. The produce of the Western side of Borneo, by far the largest, have been estimated as low as 52,000 ounces. and this by parties reckoning the Chinese population of the same country, most of it engaged in gold washing, as high as 125,000. On the other hand, Sir Stamford Raffles estimated the total annual produce of the Western part of Borneo as high as 225,335 ounces, which at the value of 3*l*. 17*s*. the ounce, would give a total value of 867,539*l*. Mr. Logan estimates the total produce of the Malay Peninsula at no more than 20,000 ounces. I have never heard of any attempt at estimating that of Sumatra, Celebes, or the two Philippine Islands.—*Crawfurd Dict. page* 144. In China, Gold is collected in the sands of the rivers in Yunnan and Sz'chuen, especially from the upper branch of the Yangtsze-kiang called Kinsha-kiang or Golden sanded river, from this product. The largest amount is said by Davis to come from Likiang fu near that river and from Yungchang fu on the borders of Burmah. It is wrought into personal ornaments and knobs for official caps, and beaten into leaf for gilding, but is not used as a coin, nor is much found in market as bullion. Silver is brought from Yennan, near the borders of Cochin China and the mines in that region must be both extensive and easily worked to afford such large quantities as have been exported during the last five years. —*Williams' Middle Kingdom, page* 144. Gold is found in many parts of the Japanese Empire, sometimes it is obtained from its own ore, sometimes from the washings of the earth or sand and sometimes it is mixed with copper. The quantity in the country is undoubtedly great. An old Spanish writer of the seventeenth century tells us that in his day the palace of the Emperor at Yedo, as well as many houses of the nobility were literally covered with plates of gold. In the beginning of the Dutch trade the annual export was £840,000 sterling and in the course of sixty years the amount sent out of the kingdom through the Dutch alone was from twenty five to fifty millions sterling. Silver mines are quite as numerous as those of gold. In one year the Portuguese, while they had the trade, exported in silver £587,500 sterling. Copper abounds throughout the whole Japanese group and some of it is said to be not surpassed by any in the world. The natives refine it and cast it into cylinders about a foot long and an inch thick. The coarser kinds they cast into round lumps or cakes. Quicksilver is said to be abundant, but this, so far as we know, has never been an article of export Lead also is found to be plentiful, but like quicksilver it is not been sent out of the kingdom. Tin has also been discovered in small quantities, and of a quality so fine and white that it almost equals silver, but of the extent of this mineral little is known, as the Japanese do not attach much value to it, and therefore have not sought for it. Iron is found in three of the provinces, and probably exists in others. The Japanese know how to reduce the ore, and the metal they obtain is of superior quality, of which they make steel unsurpassed in excellency. Coal :—"They have no want of coals in Japan," says Kœmpfer, "they being dug up in great quantities in the province of Sikusen and in most of the northern provinces." Dr. Siebold also speaks of coal as being in common use throughout the country, and on visiting one of the mines he saw enough to convince him that it was skilfully worked. For domestic purposes they convert the coal into coke. Viewed in the light of commercial intercourse between the two hemispheres, this coal is worth more than all the metallic deposits we have enumerated Native sulphur.—In a region so volcanic, this is, as might be expected an abundant mineral. In some places it lies in broad deep beds, and may be dug up and removed with as much ease as sand. A considerable revenue is derived by the government from sulphur.—*American Expedition to Japan, p.* 76.

(4110) GOMPHIA AUGUSTIFOLIA, is a native of Ceylon and the continent of India. The root and leaves are bitter. It is employed in Malabar in decoction, in milk, or water, as a tonic, stomachic, and anti-emetic.—*O'Shaughnessy, page* 269.

(4111) GOMPHRENA GLOBOSA. GLOBE AMARANTH; Everlasting flower. Gomphrena. Amaranthaceæ. Globe Amaranth.

Gool mukhmul, HIND. | Jafferee Goondee, DUK.

Both red and white varieties cultivated in gardens.—*Gen. Med. Top. page* 187. Annual: common in most gardens. The native women wear the flowers in their hair. It resembles red clover.—*Riddell.* In the Tenasserim Provinces, the globe amaranthus is often cultivated by Karens and Burmans, as well as by Europeans. —*Mason.*

(4112) GOMUTO OR EJOO (*Arenga saccharifera*, Labill.; *Saguerus Rumphii*).

Anou, SUMATRA.	Makse, AMB.
Gomuti, ENG.	Seho, TER.
Sagwire, PORT.	Duke or Dok, JAV.
Iju or Ejoo, or See jee. MAL.	Cabo negro, SP.

The *Gomuto* or *Ejoo* fibre, so well known in Eastern commerce and as used in Eastern shipping, is hardly known in the Western world. It is, however, occasionally heard of by the name of "vegetable bristles." Though a portion of the fibres may be likened to stiff bristles, the greater part is more like black horse-hair. This is celebrated, in the countries where it is produced, both for its strength and for its imperishable nature, even when exposed to wet. It is supposed to be the same as the *Cabo negro* of the Spaniards of Manilla. The tree yielding it was described and figured by Rumphius ('Herb. Amb.,' i, p. 57, t. 13) under the name of Gomuto, or *Saguerus;* but the latter name being too similar to that of the true Sago tree, has been changed to *Arenga*, from the native name *Areng*, under which it was described by Labillardiere. The specific name has been given from the large quantity of sugar procurable from its sap by cutting the spadices of the male flowers. We thus observe that the tree is valuable for several very distinct, and all very useful products. It is described by Marsden, in his 'Sumatra,' under the name of *Anou*, as a Palm of "much importance, as the natives procure from it *sago* (but there is also another sago tree, more productive); *toddy*, or palm wine, of the first quality; *sugar*, or jaggary; and *ejoo*." Dr. Roxburgh, writing in the year 1799, says of it: "I cannot avoid recommending to every one who possesses lands, particularly such as are low and near the coasts of India, to extend the cultivation thereof as much as possible. The palm wine itself, and the sugar it yields, the black fibres for cables and cordage, and the pith for sago, independently of many other uses, are objects of very great importance, particularly to the first maritime power in the world, which is in a great measure dependent on foreign states for hemp." This Palm is to be found in all parts, from the Gulf of Bengal to all the Asiatic islands on its eastward, especially in low moist situations and along the banks of rivers. Dr. Roxburgh describes the trees (in 1810) which had been introduced into the Botanic Garden at Calcutta about twenty-four years before, as from twenty to thirty feet in height, exclusive of foliage or fronds, which rise from fifteen to twenty feet higher. These fronds or leaves are pinnate, and from fifteen to twenty-five feet long. The trunk is straight, at first covered entirely with the sheaths of the fronds or leaves, and the black horsehair-like fibres, called by the Malays *Ejoo*, which issue in great abundance from the margins of these sheaths. As the tree advances in age and size, these drop off, leaving an elegant, columnar, naked trunk. He further states that he had observed that each of the well-grown thriving trees produces about six leaves annually, and that each leaf yields about three quarters of a pound weight of these fibres, and, therefore, each tree about four pounds and a half. But some luxuriant trees yield at least one pound of fibre from each leaf. As these black fibres issue from the sides of the sheaths, they necessarily surround the stem, and may be cut off without injury to the tree. Even in commercial specimens, some may be seen covered both on the upper and lower surface with dense cellular membranes, having between them a mass of these black fibres. These are supported by thicker or whalebone-like fibres, which are attached to the thinner fibres by cellular tissue. These stiff fibres are employed in Sumatra as styles for writing with on the leaves of other Palms, &c., as mentioned both by Marsden and Bennett. These fibres are further described as stronger, more durable, but less pliant and elastic than those of the *Coir*; but they resist decay, and are therefore more fit for cables and standing rigging, but less fit for running rigging. "The native shipping of all kinds are entirely equipped with the cordage of the *Gomuto*, and the largest European shipping in the Indies find the advantage of using cables of it. It undergoes no preparation but that of spinning and twisting,—no material similar to tar or pitch, indispensable to the preservation of hempen cordage, being necessary with a substance that, in a remarkable degree, possesses the quality of resisting alternations of heat and moisture. The best *Gomuto* is the produce of the islands farthest east, as Amboyna and the other Spice Islands. That of Java has a coarse ligneous fibre; the produce of Matura is better. Gomuto is generally sold in twisted shreds or yarns, often as low as a Spanish dollar a picul, and seldom above two; which last price is no

more than one sixth part of the price of Russia hemp in the London market. Were European ingenuity applied to the improvement of this material, there can be little doubt but it might be rendered more extensively useful." Milburn, again, in his 'Oriental Commerce,' mentions the Ejoo as of all vegetable substances the least subject to decay, and that it is manufactured into cables, and the small cordage of most of the Malay vessels made of it: "it is equally elastic with coir, but much more serviceable, and floats on the surface of the water." These fibres are universally employed, in the countries where the trees are indigenous, for making cordage for their nets and seines, as well as for the rigging of their vessels, as also cables. These are described by all as remarkable for their tenacity and durability, and as not undergoing any change by exposure to wet, not even when stowed away in a wet state. In some experiments made by Dr. Roxburgh, some thickish cord bore 96 lb., and some smaller 79 lb.; while coir of the same size bore only 87 lb. and 60lb. respectively. Besides the above horsehair-like fibres, there is at the base of the leaves a fine woolly material (baree), much employed in caulking ships, as stuffing for cushions, and as tinder. Ejoo was sent to the London Exhibition of 1851, *via* Singapore, from Malacca, as separated from stiff fibres, and as prepared for manufacture or export, and prepared as sinnet or coarse line for making ropes or cables. The portion belonging to each leaf having apparently been cut off close to the sheath, and each measuring about three feet in breadth and two feet in length. The bundles of the coarse and fine fibres are about six feet in length, and about twelve inches in diameter, neatly tied up with split cane. Interspersed among the coarser, there are some finer fibres, something like black wool. The sinnet is coarse, but strong, and broke with a weight of 85lb., when coir of about the same size broke with 75 lb.; but the comparison is not very exact. Mr. Kyd, the celebrated ship-builder of Calcutta, possessed a cable made of the Ejoo fibre, which he had had for four years exposed to all weathers, and which raised the bow anchor of a merchant ship of 500 tons, buried in the sands of the Hoogly; in two previous attempts at which, three Russian hempen cables had given way. Besides making strong and durable cordage, the Ejoo fibre is no doubt applicable to a variety of purposes for which horsehair and bristles are now employed. *Fib. Pl. p.* 99. Seeman tells us that Gomuti is a horse-hair looking substance produced at the base of the petioles of the Arenga saccharifera, and is known by various names in the languages of the Archipelago. This fibrous substance is superior in quality, cheapness and durability to that obtained from the husk of the Cocoa-nut. It has great power in resisting wet, and is used by the natives of the Indian islands for every domestic and naval purpose to which cordage, is applied, a practice in which Europeans have of late years imitated them. The coarser parts are used as pens by all the tribes who write on paper, and as the arrows for blow pipes or arrow-tubes. The Gomuti, of all vegetable substances, is the least prone to decay, it is fastened like straw over the bamboo thatch: round the ends of posts placed in the ground: mixed with mortar: and is planted by the Burmese into ornaments of the arms, legs and neck. The Arenga saccharifera tree produces about six leaves annually, and each leaf yields from eight to sixteen ounces of clean fibres.—*Seeman.* See ARENGA SACCHARIFERA.

(4113) GOODIA LATIFOLIA. LEGUMINOSÆ. This genus of flowering plants are all natives of New Holland, colour of the flowers yellow, they never attain any great height, they may be raised from seed or cuttings, in a loamy soil.—*Riddell.*

(4114) GOOGULL FIBRE is supposed to be obtained from the Isora corylifolia, the Valumbrikaya of the Tamils.

(4115) GOOLAB, distilled rose water, prepared also in India, but largely imported from the Persian Gulf.

(4116) GOONCII. Roots of Abrus precatorius. An Indian substitute for liquorice.

(4117) GOONG.

Goong, Goonch, GUZ. & HIND.

A little red and black seed, obtained from the pod of a plant (*Abrus precatorius*), growing wild in Southern Asia and also met with in some parts of Africa and America. These seeds are used in India as weights by jewellers, and also for bracelets, necklaces, and other trinkets.—*Faulkner.*

(4118) GOOR, SACCHARUM OFFICINARUM.

Goor, Duk. | Bellnm, TEL.
Nullavellum, TAM. | Jaggary, ENG.

A very coarse kind of sugar obtained from the Sugar cane.—*Ainslie, Met. Med. pdge* 266.

(4119) GOORAKIEME. A soft, fine, but open-grained, light Ceylon wood.

(4120) GOORAKOO; Goodakoo or Goodak; called in Bengal Tambakoo, the name given in the Peninsula of India to the compound of tobacco for the *hookah*; from *goor* raw sugar and *akoo* Tel: leaf.—*Herklots.*

(4121) GONG OR LOO, a Chinese musical instrument, composed of a mixed metal, (said to be tin, copper, and bismuth), resembling bronze in appearance. It is in the form of a large flat basin, with a ridge; and, when beaten with a stick or mallet, covered with woollen cloth or twist, emits a strong reverberating sound. Its value is in proportion to the quantity of metal it contains.—*Crawfurd Dict.*

(4122) GOPI-CHUNDUN, an aluminous yellow earth, brought from the ganges at Hurdwar, to Ajmere, and used to mark the foreheads of those who worship Vishnu: also given in medicine.—*Gen. Med. Top. p.* 131.

(4123) GOROCHAMUN: BEZOAR.

(4124) GORDONIA FLORIBUNDA. A species of Gordonia is a conspicuous tree in Maulmain. It belongs to the same family as the tea plant, and the camelias of which the japonicas are such favorites, and is a member of the same genus as the American loblolly bay, and Franklinia, to which the flower bears a strong resemblance. Wallich has named the Tenasserim tree the abundant flowering gordonia, but there is some difference between the Tavoy and Maulmain trees; whether enough however to constitute different species, is doubtful. The Maulmain tree has leaves precisely like *G. obtusa* "with shallow serratures;" but the leaves of the Tavoy tree are quite entire. The Burmese have different names for them. The timber of Gordonia floribunda, and Gordonia integrifolia is called "itch-wood" by the Tavoyers, from the itching which its chips or bark occasion when brought in contact with the skin. Mr. Mason has often seen its compact timber used for house posts, and for rice mortars.—*Mason.*

(4125) GORDONIA WALLICHII, is their most common tree much prized for ploughshares and other purposes requiring a hard wood: it is the "Sing-brangkun" of the Lepchas, and in Sikkim ascends to 4000 feet. Oaks at this elevation occur as solitary trees, of species different from those of Darjiling. There are three or four with a cup-shaped involucre, and three with spinous involucres enclosing an eatable sweet nut; these generally grow on a dry clayey soil.—*Hooker Him. Jour. Vol.* I. *page* 157.

(4126) GOSSAMPINUS RUMPHII. ERIODENDRON ANFRACTUOSUM. White cotton tree. The white cotton tree does not grow spontaneously in Tenasserim, but is often planted, and the floss, which it yields abundantly, is preferred to the product of the red cotton tree.—*Mason.*

(4127) GOSSYPIUM.

Thoothee, TEL. | Pungee, TAM.
Kuppass, HIND. |

A genus of Plants belonging to the natural order *Malvaceæ*, common to both the Old and New World, and which, from the hair, or cotton, enveloping its seeds being so admirably adapted for weaving into cloth, is, after those affording food, one of the most important groups of plants. There can be no doubt that it is indigenous in America, as, besides the distinctness in species, specimens of cotton still attached to the seeds, as well as cloth fabricated from the former, have been brought by Mr. Cumming from the Peruvian tombs. Some of the cloth, consisting of chequered squares of black and white, very nearly resembles some modern patterns. Humboldt has moreover stated that it formed the only clothing of the natives of Mexico, and is one of the plants they most anciently cultivated. With respect to the Old World, the almost universal use of cotton as clothing in the East is well known; and as the species, so far as ascertained by botanists, appear to be Indian and Chinese, the historical investigation is interesting as proving an early communication between the civilised nations of remote antiquity. Though Rossellini incorrectly states that cotton was employed as mummy-cloth, it must have been known to the ancient Egyptians, as he found some of the seed in one of the monuments of Thebes. In later times, we learn from Arrian that muslin was exported from India to the Arabian Gulf, and from that country cotton was no doubt first made known to the rest of the world. The Sanscrit name of the Cotton-Plant is 'karpasi,' and the Hindoo 'kupas;' the cotton itself is in the latter language called 'rooi.' The former is interesting, as 'karpasus' occurs in the "Periplus' of Arrian, and is rendered by Dr. Vincent 'fine muslin.' It is derived from the Sanscrit 'karpasi,' from which probably, as indicated by the editor of 'Harris's Dictionary,' the Hebrew word 'karpas,' employed in the book of Esther (chap. i. v. 6), is also derived; so likewise the Latin 'carbasus.' Dr. Royle, in his 'Essay on the Antiquity of Hindoo Medicine (note, p. 145), infers, that as in the above passage of Esther, white, green, and blue hangings fastened to pillars of marble, are described in the court of the garden of the king's palace; the practice appears similar to what is now adopted in India, where calico curtains, usually in red and white stripes, and stuffed with cotton (commonly called 'purdahs'), are employed everywhere in India, and at Delhi even in the king's hall of audience. This consists of colonnades of pillars supporting a light roof in the court before the private apartments of the palace. On the outer rows of pillars these purdahs are suspended; hence, the author infers, we may understand the use to which were applied the rows of pillars in front of the palace in the ruins of Persepolis. Cotton was no doubt in later times cultivated and manufactured into cloth. Pliny (lib. xix. c. 1) states that Upper Egypt produces a small shrub which some call 'gossypion,' others 'xylon, bearing fruit like a nut, from the interior of which a kind of wool is produced, from which very white and soft cloth is manufactured. Had it been common in Egypt in the time of Herodotus, it could not have escaped him; as he says specially of the Indians, that they possess a kind of plant which, instead of fruit, produces wool of a finer and better quality

than that of sheep: of this the natives make their clothes. Nearchus describes the dress of the Indians as being made of flax from trees ('Library of Entertaining Knowledge,' Egypt. Antiq., ii. p. 125). Theophrastus (lib. iv. c. 9) clearly describes the cotton with leaves like the vine as being abundant in the Island of Tylos in the Persian Gulf. Heeren, in his work on the 'Commerce of the Ancients,' comes to the conclusion that these plantations of cotton in the Island of Tylos were the result of the commerce with India, the true country of the cotton. The inferences from these quotations of the original introduction of cotton from India into Egypt are in some measure confirmed by there being no species of *Gossypium* indigenous and peculiar to the latter country. In conclusion, it is necessary to refer to the facility with which cotton is distinguished from linen to controvert the assertion of Rossellini that it was always employed for mummy-cloth; as the result of numerous observations by Bauer, &c., with the most powerful microscopes of modern times, and every variety of mummy-cloth, has proved that it is invariably composed of linen, and not of cotton cloth. The one fibre is easily distinguished from the other; that of cotton having a flat tape or riband-like appearance, while the fibre of the linen has a round tubular and even-jointed structure. (Egypt. Antiq., 'Library of Entertaining Knowledge,' vol. ii. p. 182). The genus *Gossypium* is characterised by having a double calyx, of which the inner is cup-shaped, obtusely 5-toothed, the outer or involucre tripartite, with the leaflets united at the base, cordate, with the margins irregularly cut. Stigmas, 3-5. Capsules, 3- or 5-celled, many-seeded. Seeds clothed with wool-like hairs, or cotton. The species of *Gossypium* occupy naturally a belt probably exceeding the torrid zone in breadth, but in a cultivated state we have cotton now extending on one hand to the south of Europe, and Lower Virginia and even Maryland in the United States of America; while on the other we have it as far south as the Cape of Good Hope, and in America to the southern parts of Brazil. Within these limits it may also be seen cultivated at considerable elevations. Baron Humboldt mentions having seen it even at 9000 feet of elevation in the Equinoctial Andes, and in Mexico at 5500 feet. Dr. Royle states that it is cultivated in small quantities at 4000 feet of elevation in 30° N. lat. in the Himalayas. The localities suited for the production of cotton depend as much upon the climate as the soil, and also upon the specific peculiarities of the different kinds of cotton plants. That the production of cotton is so much influenced by external circumstances is not more remarkable than in many other cultivated plants; indeed, we might expect it to be more so from the susceptibility of its hairy development to the influence of situation. Humboldt has remarked that *G. Barbadense*, *G. hirsutum*, and *G. religiosum* flourish in a climate where the mean annual temperature is from 82° to 68°; but that *G. herbaceum* is successfully cultivated where, the summer heat being 75° or 73°, that of winter is not less than 46° or 48°. The cultivation of the cotton however does not depend so much on winter cold as on sufficient length of suitable summer heat. The thermometer in Upper Virginia is sometimes as low as zero of Fahrenheit in winter, and yet cotton can be cultivated during the long summer. It is remarkable that a genus so important for its product, and so long known, and with comparatively so small a number of species, should yet have these undetermined. The celebrated De Candolle states, that no genus more urgently requires the labours of a monograph from a careful botanist who could have the opportunity of seeing the species in a living state. The confusion has in a great measure proceeded from botanists absurdly neglecting the cultivated in their search for new species; and cultivators being incompetent or unwilling to distinguish varieties from species, frequently raising the former to the rank of the latter, because the produce, in which alone they are interested, happened to be more or less valuable. In the proceedings of the East Indian Committee there is an interesting letter from Mr. Spalding, where he informs us that the American cultivators confine their attention to such plants as are of annual growth. 1st. The Nankeen Cotton, introduced at an early period. This is abundant in produce; the seed covered with down, the wool of a dirty yellow colour, and usually low priced. 2nd. The Green Seed Cotton with white wool, which, with the former, is grown in the middle and upland districts, whence the latter is called Upland Cotton, also Short Staple Cotton, and, from the mode in which it was cleaned, Bowed Georgia Cotton. 3rd. The Sea-Island or Long Staple Cotton, which is distinguished by the black colour of its seed, and by the fine, white, strong, and silky long staple by which it is surrounded. This is grown in the lower parts of Georgia and South Carolina, near the sea, and on several small islands which are not very distant from the shore. The species admitted by botanists are not yet clearly determined. M. De Candolle admits 13 species, and notices others. Two have since been described by Dr. Roxburgh, one by Rœusch, and another in the 'Flore de Senegambie.' Of varieties Mr. Bennett says he knows more than one hundred kinds, and that they appeared to him never ending. Dr. Royle, the most recent author who has treated expressly of the species, admits eight species, in which are absorbed some of De Candolle's; while others are avowedly unnoticed for want of materials for satisfactory determination. But from his own observations, Dr. Roxburgh's 'Flora Indica,' as well as from Swartz, 'Observ.

Bot.' for the West Indies, and the specimens, though few, in the British Museum, it is probable that several of the cultivated species are correctly determined.

(4128) GOSSYPIUM HERBACEUM, Linn., which is herbaceous in temperate, and usually with bitriennial stems 4-6 feet high in tropical countries, is no doubt the *Xylon* s. *G. antiquorum*, and includes also the *G. Indicum* of Lamarck, which would indeed be the preferable name for this species. The younger parts of the stem, as well as the flower and leaf-stalks, hairy and marked with black spots. Leaves hairy, palmate, 3- (generally) 5-lobed, lobes broad and rounded with a little point, or in the woody varieties sub-lanceolate and acute, Stipules falcate, lanceolate. Flowers of a lively yellow colour, with a purple spot near the claw. Segments of exterior dentate, sometimes entire. Capsules ovate, pointed, 3- or 4-celled. Seeds free, clothed with finely-adhering grayish down under the short-staple white wool. This and its varieties are those chiefly cultivated in India. It has been procured from China and the Malayan Peninsula, and also from Egypt.

(4129) GOSSYPIUM PUNCTATUM, from Senegambia, is probably a variety. It is that cultivated in the Mediterranean region, and must have been the species taken to America from Smyrna.

(4130) GOSSYPIUM ARBOREUM, Linn. Stem arboreous, 15-20 feet, sometimes shrubby, young parts hairy, tinged of a reddish colour. Leaves palmate, 3- or 4-lobed, hairy, dotted with blackish spots of a dark green colour; lobes elongated, lanceolate, sometimes mucronate, sinus obtuse, glands one, sometimes three. Stipules oval-shaped. Flowers solitary, with short peduncles, red, with a yellowish tinge near the claws. Leaflets of the exterior calyx cordate, ovate, entire, sometimes dentate. Capsule ovate-pointed, 3- or 4-celled, seeds covered with a greenish coloured fur, enveloped in fine silky yellowish-white wool. This species is found in the island of Celebes and in every part of India. It is noticed among lists of the plants of Arabia, and also of Egypt. It is planted near temples and habitations of Faqueers in India, and is stated to be sacred to the Hindoo deities, and therefore employed only for making muslin for turbans. The species is marked *G. religiosum* in Heyne's 'Herbarium,' and one specimen of *G. Barbadense* is marked *G. arboreum* in the 'Linnean Herbarium.'

(4131) GOSSYPIUM RELIGIOSUM, Perennial. Stem 3-4 feet, branches and petioles a little velvety, hirsute towards the apex, and covered with black points. Leaves cordate, superior 3-lobed, inferior 5-lobed, deeply divided; lobes ovate-acuminate, entire, pubescent (some of the lower ones ovate-acuminate), one to three glands; stipules lanceolate, deciduous (cordate-acuminate, Roxb.) Flowers large, fulvous, peduncles short dotted; leaflets of the exterior calyx large, cordate-acuminate, deeply laciniate, hairy and dotted; capsule ovate-acuminate, dotted, 3- 4- or 5-celled; seeds black, covered with firmly-adhering short tawny fur under the long tawny-coloured wool. There is considerable confusion with respect to the species which should be called *G. religiosum*. The distinguishing characteristic of what is considered such at present is the having tawny-coloured instead of white wool. There are at least two distinct localities for this kind of cotton, one Siam, the other China. From the latter country it was introduced both into India and America under the name of Nankin Cotton. Dr. Royle is of opinion that two distinct species yield tawny-coloured cotton; one with small velvety-looking leaves and much dotted in every part, of which he has seen specimens from Macao, Tahiti, and Guzerat. The other is a much larger plant, with the general appearance and leaves of *G. Barbadense*, of which there are specimens in the 'East Indian Herbarium.' Mr. Wilkinson has brought specimens from Egypt of a rather tawny-coloured cotton, with brownish seed, free from fur, which he says is there called 'gotun' Hindee.'

(4132) GOSSYPIUM HIRSUTUM, Linn., Shrubby, about six feet high, young pods very hairy. Leaves, the upper undivided, cordate, acute; the lower 3- or 5-lobed; lobes ovate, acute (triangular, Roxb.), hairy on the under and smooth on the upper surface. Petioles very hairy, dotted with black spots; glands 1 or 2 to 3; stipules lanceolate (Cavanilles); corolla, base yellow, purplish towards apex (uniform yellow, Roxb.); exterior calyx ovate-acute, very hairy, cordate, 3-toothed (Cav. laciniate, Roxb.); capsule large, ovate-acute; seeds many, free, clothed with firmly-adhering green down under the fine long white wool. (Swartz.) This species is cultivated in Jamaica, according to Swartz; and would appear, from the description of the seed to be the Green-Seeded, Short-Staple, or Upland Cotton of the Americans.

(4133) GOSSYPIUM BARBADENSE. Stem shrubby, 6-15 feet, smooth; leaves, the upper 3-lobed, the lower 5-lobed; lobes ovate, acute, smooth, often pubescent on the under surface; leaflets of exterior calyx large, deeply laciniate; flowers yellow; capsule ovate, acuminate, smooth; seeds 8-12, free, oblong, black, and without any other pubescence than the long fine easily-separable cotton. Swartz describes this species as extensively cultivated in the West Indies: it is also the *G. vitifolium* of Cavanilles. Is one of the cultivated cottons of Egypt. It is more than probable that the Sea-Island or Long Staple Cotton is a variety of this species, as its seeds agree in character. More than this it is not possible to say, as, among the numerous collections which London contains, strange to relate, there are

none in which genuine specimens of cultivated cottons, properly named, can be seen; but it is to be hoped that travellers and naturalists will be induced to pay a little more attention to the products of a country, whether natural or the result of art, and deposit them in our museums, with the plants which produce them. Several other species, as *G. punctuatum*, from Senegal; *G. obtusifolium*, from Ceylon; and *G. peruvianum*, from Brazil, have been described; but Dr. Royle is of opinion that all the species of cotton may be reduced to four—*G. peruvianum* (*G. acuminatum*); *G. Indicum* (*G. herbaceum*); *G. arboreum*; and *G. barbadense*. For further information the reader is referred to the works quoted above, and to Royle's 'Illustrations of the Botany, &c., of the Himalayan Mountains.' COTTON, article.

(4134) GOSSYPIUM NIGRUM. This is an ornamental tall growing shrub generally cultivated in gardens on account of its dark red flowers;—from the staple of the wool being short although fine, it is not of much value.

(4135) GOUR. [BOVIDÆ.]

(4136) GOURD, a kind of fruit obtained from various plants of the natural order *Cucurbitaceæ*. In countries having hot and dry summers the different kinds of this fruit are held in high estimation, and are a valuable article of consumption, acquiring a very large size, abounding in nutritious matter, and being moreover very wholesome. The largest is the kind called Potiron Jaune by the French, which sometimes weighs above 2 cwt. All the most esteemed kinds belong to genus *Cucurbita*, the species of which are almost entirely destitute of the bitterness that renders other fruits of the same natural order unfit for food; thus the Vegetable Marrow is supplied by the *Cucurbita ovifera;* the Potiron by *C. maxima;* the Squash-Gourd, a very delicate sort, and perhaps the most agreeable of all when cooked in a very young state, by *C. melopepo;* and the Orange-Gourd by *C. aurantia*. Bottle-Gourds, which are bitter and dangerously drastic, are the fruit of *Lagenaria vulgaris;* while what is called the Colocynth-Gourd, a powerful purgative, is in reality a kind of melon, the *Cucumis colocynthis*. —*Eng. Cyc.* A coarse genus of the cucumber family, generally cultivated throughout the year, of comparatively little value as a vegetable, requires rich soil and plenty of room; it is not commonly known, that the young shoots of all the edible varieties of gourds are an excellent vegetable, used as spinach.—*Jaffrey*.

(4137) GOWDIE, a name for the fish called the Sword Dragonet. [CALLIONYMUS.]

(4138) GRAINS OF PARADISE are hot, acrid, aromatic seeds, produced upon the coast of Guinea, and used for medicinal and other purposes as stomachic and cordial stimulants. They are produced by the *Amomum Grana Paradisi* of Linnæus, and *Amomum grandiflorum* of Smith. [AMOMUM.]—*Eng. Cyc.*

(4139) GOUGHIA, a curious evergreen laurel-like tree, was found by Dr. Hooker at Chating in the Lachen valley of Sikkim. This fine plant was named (Wight, "Ic. plant.") in honour of the Hon'ble Capt. Gough, son of the late Commander-in-chief, and an officer to whom the botany of the Peninsula of India is greatly indebted. It is a large and handsome evergreen, very similar in foliage to a fine rhododendron, and would prove an invaluable ornament on English lawns, if its hardier varieties were introduced into this country.—*Hooker, Him. Jour. Vol.* II *page* 33. Wight in Icones gives Goughia, *Griffithiana*, 1877; and Neilgherrensis, 1878-79.

(4140) GOWLA.

Gowla, GUZ. HIND. | Gewla, TAM.

A brown coloured seed, about the size, and having much the same appearance as the coriander seed, but more oval. They have a pleasant, subaromatic and mucilaginous taste; and are considered by native practitioners as cordial and stomachic. They are imported into Bombay from the Persian Gulf, and are distinguished in the bazars either with or without shells, or more strictly speaking, husks.—*Faulkner*.

(4141) GRACILLARIA LICHENOIDES, One of the Algæ, highly valued in Ceylon.

(4142) GRACILLARIA TENAX, the Fucus tenax of Turner; about 27,000 lbs. are annually imported into Canton, from the provinces of Fokien and Tchi-Kiang, and sold for 6d. to 8d. the pound. The Chinese make it the basis of an excellant glue and varnish, and employ it chiefly in the manufacture of lanterns, to strengthen or varnish the paper and sometimes to thicken or give a gloss to silks or gauze. Mr. Neill thinks that the gummy substance called Chin-chou, or hai-tsai, in China and Japan may be composed of this substance. Windows made of slips of Bamboos and crossed diagonally, have frequently their interstices wholly filled with the transparent glue of hai-tsai.

(4143) GRACULA RELIGIOSA, (Linnæus,) the Mina-Bird, is the Beo and Mencho of the Javanese, Teeong of the Sumatrans, and is referred by Mr. Swainson to the *Sturnidæ*. Mr. G. R. Gray arranges it under the family *Corvidæ*, in the sub-family *Graculinæ*. M. Lesson places this bird next to the Rollers, and among the *Eurystomidæ*. It is found in Java, Sumatra, and the great Eastern Islands. Insects and fruits form the food of the Mina Bird which is easily tamed, and learns to whistle and talk with great facility. With the natives it is a great favourite in consequence. Marsden says of it, that it has the faculty of imitating human speech in greater perfection than any other of the feathered tribe.—*Engl. Cyc. page* 139.

(4144) GRAM.

Kooltees Chunna, Guz. Hind.

A name given in oriental commerce to the produce of two leguminous plants cultivated in India, chiefly used for feeding horses, cattle, &c. See Cicer and Dolichos.—*Faulkner.*

(4145) GRANADILLA. Passiflora quadrangularis. This luxuriant exotic from the Jamaica passion flowers, flourishes well on the Tenasserim Coast, and is very prolific. The smooth oblong fruit grows nearly as large as a cucumber, and contains a succulent pulp, which make a cooling delicious dish, and when prepared in tarts, can scarcely be distinguished from green apple. The Rev. Mr. Bennett of Tavoy, has recently introduced it among the Karens, by whom it is highly esteemed, and much sought for. It will no doubt soon be generally diffused through the Provinces, as it possesses all the attractive qualities of fine fruit, handsome fragrant blossoms, and when trailed over an arbor, a rich pleasing shade.—*Mason.*

(4146) GRAPES. Vitis vinifera.

Kodimoondric pullum, Tam.	Dracha pundoo. Tel.
Anub, Arab.	Booaangoor, Malay.
Dakah. Hind.	Vitis vinifera. Lin.
Junb, Arab.	Dracha, Sans.
Raisins, Fr.	Booangoor, Mal.
Trauben, Ger.	Uvæ, Lat.
Darakh, Guz.	Ungoor, Pers. and Duk.
Ungoor, Hind.	Uvas, Port.
Grappi, It.	Ubas, Sp.

Grapes grow in abundance in India, in private gardens, but no wine is made from them.—*Ains. Met.Med.p.*19. A well-known fruit produced from the Vine, which is cultivated in all warm and tropical climates—France, Spain, Portugal, and Italy, as well as some parts of Hungary and Persia, produce grapes which yield wine of various qualities and flavour. They are also extensively produced in various parts of India.—*Falk.* Vitis indica, produces beautiful clusters of round purple berries and a large grape which is very fair eating: it is not the common vine of Europe which nevertheless is probably this Himalayan plant, the *Vitis indica.* The origin of the common grape being unknown, it becomes a curious question to decide whether the Himalayan *Vitis Indica* is the wild state of that plant: a hypothesis strengthened by the fact of Bacchus &c. having come from the East.—*Hooker, Him. Vol.* II. *p.* 187.

(4147) GRAPHIC SLATE. A slate that "soils and writes," as Dr. McClelland described it is found east of Tavoy, and another and softer variety is found in Maulmain near Tremenheerite. They may be justly regarded as varieties of graphic slate.—*Mason.*

(4148) GRAMINACEÆ or GRASSES, are a very extensive and important natural order of Endogenous Plants, comprehending many of the most valuable pasture plants, all those which yield corn, such as wheat, barley, and maize, the sole source of colonial sugar in the sugar-cane, and the most fragrant of all plants in the form of Andropogons. Their structure is among the most simple of the perfect forms of vegetation; a stem clothed with alternate leaves whose stalks are universally thin, and constituting as many sheaths to guard the young and rapidly growing shoots, a few rudimentary leaves collected at the ends of the branches of inflorescence, and constituting flowers a very small number of stamens, and a single seed inclosed in a thin pericarp, are all that nature provides to enable these plants to preserve their race and to distinguish their numerous kinds from one another. Yet with such a simple apparatus, many thousand species are so precisely characterised that the natural order of Grasses is perhaps, one of the easiest to study and arrange, provided the task be commenced upon right principles. The floral leaves, called glumes, paleæ, and scales, offer a prodigious number of different appearances, according to the manner in which they are combined or modified; and the inflorescence, the number of stamens, the texture of the parts, or the relation of the sexes to each other, afford additional means by which the distinctive characters are varied. This is, no doubt, one of the wise provisions of Providence by which man is enabled to distinguish good from evil, the useful from the useless, the profitable from the unprofitable. For in no class of plants is it more necessary than in grasses to know how to choose between different species. For instance, most grasses are saccharine and nutritious to cattle, but the species of *Holcus, Bromus,* &c., are as frequently worthless. There is a great difference between the value of grasses for pasture; certain kinds suit the meadows, others marshes, others upland fields, and others bleak and sterile hills, where they furnish valuable food for sheep: these kinds will not grow indiscriminately, or are not equally suitable for different soils and situations, and it is therefore essential for the husbandman that he should be capable of discriminating between them. Some indicate the quality of soil: the species of *Dactylis, Holcus,* and *Bromus* are inhabitants of sterile land; the *Festucæ* and *Alopecuri* of better soil: while various *Poæ* and *Cynosurus* are found only in pasture-land of excellent quality. Most grasses are perfectly harmless, if not nutritious; yet the single species *Lolium temulentum* is a deleterious species in the midst of harmless *Lolia*; and *Bromus purgans* and *Festuca quadridentata* afford similar instances of this singular exception to ordinary rules. For these and similar reasons, classification, which at all times is so necessary, here becomes the very foundation of all correct knowledge, and it has accordingly very particularly excited the attention of systematic botanists from the time when the general term *Gramen* was broken up by Linnæus into a num-

ber of different genera. It is not desirable in this place to show by what degrees the knowledge of botanists upon this subject has advanced from the days of Linnæus up to the present time. Those who are desirous of gaining this information should consult Palisot de Beauvois' 'Agrostographie, published at Paris in 1812, and the subsequent writings of Brown, Kunth, Nees von Esenbeck, and Trinius. "The distribution of cultivated grasses is one of the most interesting of all subjects. It is determined not merely by climate but depends on the civilisation, industry, and traffic of the people, and often on historical events. Within the northern polar circle agriculture is found only in a few places. In Siberia grain reaches at the utmost only to 60°, in the eastern parts scarcely above 55°, and in Kamtschatka there is no agriculture even in the most southern parts (51°). The polar limit of agriculture on the north-west coast of America appears to be somewhat higher, for in the more southern Russian possessions (57° to 52°) barley and rye come to maturity. Only in Europe, namely in Lapland, does the polar limit reach an unusually high latitude. Beyond this dried fish, and here and there potatoes, supply the place of grain. The grains which extend farthest to the north in Europe are barley and oats. These, which in the milder climates are not used for bread, afford to the inhabitants of the northern parts of Norway and Sweden, of a part of Siberia and Scotland, their chief vegetable nourishment. Rye is the next which becomes associated with these. This is the prevailing grain in a great part of the northern temperate zone, namely in the south of Sweden and Norway, Denmark, and in all the lands bordering on the Baltic, the north of Germany, and part of Sibra. In the latter another very nutritious grain, buckwheat, is very frequently cultivated. In the zone where rye prevails wheat is generally to be found, barley being here chiefly cultivated for the manufacture of beer, and oats supplying food for the horses. To these there follows a zone in Europe and Western Asia where rye disappears, and wheat almost exclusively furnishes bread. The middle and the south of France, England, part of Scotland, a part of Germany, Hungary, the Crimea and Caucasus, as also the lands of middle Asia, where agriculture is followed, belong to this zone. Here the vine is also found, wine supplants the use of beer, and barley is consequently less raised. Next comes a district where wheat still abounds, but no longer exclusively furnishes bread, rice and maize becoming frequent. To this zone belong Portugal, Spain, part of France on the Mediterranean, Italy and Greece, further, the countries of the East, Persia, Northern India, Arabia, Egypt, Nubia, Barbary, and the Canary Islands; in these latter countries however the culture of maize or rice towards the south is

always more considerable, and in some of them several kinds of *Sorghum* (Doura) and *Poa abyssinica* come to be added. In both these regions of wheat, rye only occurs at a considerable elevation, oats however more seldom, and at last entirely disappear, barley affording food for horses and mules. In the eastern parts of the temperate zone of the old continent, in China and Japan, our northern kinds of grain are very unfrequent, and rice is found to predominate. The cause of this difference between the east and the west of the old continent appears to be in the manner and peculiarities of the people. In North America, wheat and rye grow as in Europe, but more sparingly. Maize is more reared in the western than in the old continent, and rice predominates in the southern provinces of the United States. In the torrid zone, maize predominates in America, rice in Asia; and both these grains in nearly equal quantity in Africa. The cause of this distribution is, without doubt, historical, for Asia is the native country of rice, and America of maize. In some situations, especially in the neighbourhood of the tropics, wheat is also met with, but always subordinate to these other kinds of grain. Besides rice and maize there are in the torrid zone several kinds of grain as well as other plants which supply the inhabitants with food, either used along with them or entirely occupying their place. Such are, in the new continent, Yams (*Dioscorea alata*), the Manihot (*Jatropha Manihot*), and the Batatas (*Convolvulus Batatas*), the root of which and the fruit of the Pisang (*Banana Musa*), furnish universal articles of food; in the same zone in Africa, Doura (*Sorghum*), Pisang, Manihot, Yams, and *Arachis hypogœa*; in the East Indies and on the Indian Islands, *Eleusine coracana*, *E. stricta*, *Panicum frumentaceum*, several Palms, and *Cycadaceæ* which produce the Sago, Pisang, Yams, Batatas, and the Bread-Fruit (*Artocarpus incisa*). In the islands of the South Sea, grain of every kind disappears, its place being supplied by the bread-fruit tree, the pisang, and *Tacca pinnatifida*. In the tropical parts of Australia there is no agriculture, the inhabitants living on the produce of the sago, of various palms, and some species of *Arum*. In the high lands of South America, there is a distribution similar to that of the degrees of latitude. Maize indeed grows to the height of 7200 feet above the level of the sea, but only predominates between 3000 and 6000 feet of elevation. Below 3000 feet it is associated with the pisang and the above mentioned vegetables, while from 6000 to 9260 feet the European grains abound: wheat in the lower regions, rye and barley in the higher, along with which *Chenopodium quinoa* as a nutritious plant must also be enumerated. Potatoes alone are cultivated from 9260 to 12,300 feet. To the south of the tropic of Capricorn, wherever agriculture is practised, considerable resemblance

GRAMINACEÆ OR GRASSES.

with the northern temperate zone may be observed. In the Southern parts of Brazil, in Buenos Ayres, in Chilli, at the Cape of Good Hope, and in the temperate zone of Australia, wheat predominates; barley however and rye make their appearance in the southernmost parts of these countries, and in Van Diemen's Land. In New Zealand the culture of wheat is said to have been tried with success, but the inhabitants avail themselves of the *Acrostichum furcatum* as the main article of sustenance. Hence it appears that in respect of the predominating kinds of grain, the earth may be divided into five grand divisions, or kingdoms—the kingdom of rice, of maize, of wheat, of rye, and lastly, of barley and oats. The first three are the most extensive; the maize has the greatest range of temperature, but rice may be said to support the greatest number of the human race."—*Schouw, in Jameson's 'Philosophical Journal.'* The uses of this most important tribe of plants for fodder, food, and clothing, require little illustration. The abundance of wholesome fæcula contained in their seeds renders them peculiarly well adapted for the sustenance of man; and if theCereal Grasses only, such as Wheat, Barley Rye, Oats, Maize, Rice, and Guinea Corn, are the kinds commonly employed, it is because of the large size of their grain compared with that of other grasses; for none are unwholesome in their natural state with the exception of *Lolium temulentum*, a common weed in many parts of England, the effects of which are undoubtedly injurious. *Bromus purgans* and *catharticus* are said to be emetic and purgative; *Bromus mollis* is also unwholesome, and *Festuca quadridentata* is said to be poisonous; *Molinia varia* is injurious to cattle; and some other species are supposed to affect the milk of cows which graze upon them. Among corn-plants not generally known may be mentioned *Eleusine coracana*, called Natchnee on the Coromandel coast, and Nagla Ragee, or Mand, elsewhere in India; *Setaria germanica*, yielding German millet; and *Panicum frumentaceum*. There are many other species. The value of grasses as fodder for cattle is hardly less than that of corn for human food. The best fodder-grasses of Europe are usually dwarf species, or at least such as do not rise above four or five feet from the ground. The most esteemed are *Lolium perenne*, *Phleum* and *Festuca Pratensis*; *Cynosurus cristatus* and various species of *Poa* and dwarf *Festuca*. The fodder-grasses of Brazil are of far more gigantic stature, and perfectly tender and delicate. In Australia the favourite is *Anthistiria australis*, or Kangaroo Grass; in India *A. ciliata* is also in request; but the most common Indian foddergrass is Doorba, Doorwa, or Hurryalee (*Cynodon dactylon*). Gama Grass (*Tripsacum dactyloides*) has a great reputation as fodder in Mexico; and attention has lately been directed to the Tussac Grass of the Falklands (*Festuca flabellata*), a species forming tufts five or six feet high, and said to be unrivalled for its excellence as food for cattle and horses. The fragrance of our sweet Vernal Grass is by no means confined to it; other species possess the same quality, which is connected with the presence of aromatic secretions, which have in part recommended grasses to the notice of medical practitioners. Sugar is a general product of grasses. It exists in great quantities in the Sugar-Cane (*Saccharum officinarum*). Maize so abounds in it, that its cultivation has been proposed in lieu of the sugar-cane. —*Eng. Cyc.* This very extensive and important natural order of Endogenous plants, comprehending many of the most valuable pasture plants, all those which yield corn, such as wheat, barley and maize, the valuable sugar-cane and the most fragrant of all plants in the form of Andropogons, although seemingly simple in structure, many thousand species are so precisely characterised, that the natural order of Grasses is perhaps one of the easiest to study and arrange, provided the taste be commenced on right principles. There are 291 genera and about 4000 species, arranged with 13 tribes. Among the grasses there are both land and water, but no marine plants, and their limit is the utmost range of the vegetable kingdom. Their dissemination has depended on the civilization, industry and traffic, of people, and often on historical events. The tropical grasses have broad leaves and acquire a great height, occasionally even assume the appearance of trees; some species of Bamboo being 50 to 60 feet high. For economical purposes grasses are often of much importance, and, as fodder for Cattle their value is hardly less than that of corn for human food, and perhaps the best grass in India for this purpose is the Hurryalee, Doorba or Doorva (Cynodon dactylon). In India the sum total of described grasses is 1300 species, and the following is a list of those said to be eaten by Cattle.

Pasture grasses of India.—In the provinces, besides grain, Camels and Elephants are fed upon the leaves of various trees. The Goats, Sheep, and Cattle, are pastured upon what are called the waste land, or the jungles of the villages; the last are fed also upon chopped straw, and the stalks of the joar (Sorghum vulgare), cut into small pieces; while Horses, besides grain, are fed upon grass brought in by men called grass-cutters, but who rather scrape off the ground the creeping stems and young leaves of the grass called Doob or Dhoorba or Hurryallee. This Doob-grass (Cynodon dactylon of Botanists), which grows throughout the year, is fortunately the most common species throughout India, and succeeds particularly well in the Northern parts where lawns and pastures of moderate extent are made by planting pieces of the creeping stems of this grass. It is also much used for forming a covering for the banks of rivers, ramparts, and esplanades. The high lands of the Ballaghaut also possess a grass of which cattle are amazingly fond, and which has so strong an aromatic and pungent taste, that the flesh of the animals, as well as their milk and butter, become scented with it. This species is allied to the Lemon grass, and is very abundantly diffused towards the North-west of India. There are, however, numerous other grasses common in India which cattle delight in; but the greater number of these flourish most in the rainy season. Their rapid growth, and the great height they attain, as well as their withered and dry nature towards the close of the year, soon however unfit them for pasture grasses. The inhabitants of many parts of India remedy this, by burning down the old and dried up grass, when the young blade shoots up and affords excellent pasturage. India being at one season deluged with rain, and at another parched up with heat, with only a few months of temperate climate, cannot be expected to possess any pasture grasses similar to those of European countries. But as grasses are among the most universally diffused of plants, we find some suited to every season, indigenous in all parts of India, and affording food for its various herbivorous animals. For the purpose of pasturing improved breeds of Sheep, the hills and table-land, from Coimbatore to Kandeish, and the frontier provinces from Gujarat to Hurriana and Saharunpore, seem alone suited. But the Himalayas, enjoying a temperate climate, and a European-like vegetation, have also abundant and excellent pasturage. During the rainy season, when the temperature is moist but equable, we have many grasses resembling those in the plains. These are associated with others belonging to European genera, which are able to withstand the winter's cold: so that throughout the year nearly, there is abundant pasturage in the neighbourhood of the Himalayan villages. Of this the inhabitants avail themselves, by driving their herds of cattle, and flocks of goats and of sheep, to different ranges and elevations, according to the season of the year. The sward upon these mountains is short and thick, and very closely resembles that which we meet with on the mountains of Scotland and Wales; while the Sheep are as much esteemed for their mutton as those fed in the plains upon grain. Dr. Royle, in his Illustrations of the Botany and other branches of the Natural History of the Himalayan Mountains, has stated that these grasses belong to such genera as Agrostis, Fox-tail grass, Cat's-tail, Meadow-grass, Fescue, Cock's-food, Bent-grass, Oat-grass, and others. Also, that many of the same species which are accounted the best pasture grasses in England are among those found in the Himalayas, as Cock's-foot grass; Annual, Narrow-leaved, and smooth-stalked Meadow-grass; Cat's tail or Timothy-grass, Purple Fescue-grass, which from its greater produce is considered preferable to that specially called Sheep's Fescue-grass. In the climate where these grow naturally, nothing would be easier than the introduction of any other of the superior pasture grasses of England; but this is hardly necessary where the natural pasturage is so good. These were so much valued by the Native Governments, that some of the pasture of the Sandstone-hills, south of the Kistnah river, where the lemon grass is found, were reserved for their own cavalry, or the right to cut and sell it was rented to the highest bidders. To improve the pastures or increase the quantity of fodder in the warm and moist parts of the plains of India, it will be necessary to have recourse to the grasses of other climates, as to those of the West-Indies and of South America. The Guinea grass and the Sott's grass of Jamaica are both highly esteemed in that island, while some of the pasture grasses of Brazil and of the banks of the Amazon, are described as being of a gigantic size, and at the same time perfectly tender and delicate. Closely connected with the subject of the pasture grasses is that of providing green food for horses, camels, and elephants, and one to which little attention has been paid, though the supply has much diminished in the neighbourhood of towns and large stations. To this Dr. Wallich called attention in his evidence before the Committee of the House of Commons in 1832, stating, that for any number of animals, either for conveyance or for consumption, any quantity of food might be produced in the utmost possible abundance in India, but suggested that a more ready and plentiful supply of food for elephants and camels should be provided by planting those trees (such as particular Indian fig-trees) which form the staff of life for them, and which are extremely easily cultivated. In the Madras Presidency, considerable exertions were made about the year 1796, in every where planting what was called the Bastard Cedar

(Guazuma ulmifolia) as green food for cattle.—*Royle's Productive Resources of India.* Rye grass and clover grow well in upland districts in India, and when sown fresh have been found to answer admirably on the Shervaroy, Pulney, Baba-Boodun and Neilgherry Hills. In Guzerat, the cultivators feed their cattle on the sweet stalks of the joari and bajri.—*Spry's Suggest. page* 46.

Guinea Grass.—This grass has been cultivated to a considerable extent in India and Ceylon with more or less success according to the care and attention bestowed on it. When well manured and kept clear of weeds it grows more luxuriantly and admits of being cut every six weeks or two months. A small patch, near Colombo, which, beginning with above three quarters of an acre, has gradually been extended to above an acre and a half, has now for seven or eight years supplied 3 or 4 milch cows and from 5 to 7 horses continually with all the grass required for their consumption and has latterly left a surplus which has been dried for bedding and hay. When first planted it frequently attains a height of even 9 feet and a stalk taken promiscuously from a small patch planted lately in Combaconum measured 10 feet 4½ in length, but when cut two or three times it grows thicker but not so high. It is exceedingly excellent feeding for horses and cattle, and is generally preferred by them to the ordinary country grass, though horses which are hard worked seem to prefer the dry grass roots supplied by the grass cutters. It should not be given to cattle fresh, but the supply for one day should be cut the day previous, and it should not be cut too close to the ground but the stalk ought to be left 7 to 9 inches high. It is a good plan to move the ground between the roots every time the grass is cut and the ground should be heavily manured after every three or four cuttings. It is very hardy and may be easily propagated. It requires abundant moisture but will not live in a soil which is at all marshy. It answers best planted in small tufts 1ft. 9 in. to 2ft. apart, which rapidly spread into stools from 6 in to 1ft. in diameter.—*In Literis M.S.S.* *Lucerne* has been successfully acclimated in the Dekhan, and has long been largely cultivated by natives for sale to Europeans and for their own cattle.—*Spry's Suggest. page* 63. Besides these, the celebrated Prangos Hay plant Grass was discovered by Mr. Moorcroft, in Tibet, and found by him to be employed as winter fodder for sheep and goats, and frequently for neat cattle. Mr. M., writing from the neighbourhood of Droz, describes the Prangos Hay plant as producing fatness in a space of time singularly short, and likewise as being destructive to the River Fluke; he therefore justly concluded that it would be an invaluable acquisition to any country, to the climate of which it was suited, as its highly nutritious qualities, its vast yield, its easy

GRAMINACEÆ OR GRASSES.

culture, its great duration, its capability of flourishing on lands of the most inferior quality and wholly unadapted to tillage, impart to it a general character of probable utility unrivalled in the history of agricultural productions. When once in the possession of the ground, for which the preparation is easy, it requires no subsequent ploughing, weeding, manuring, or other operation, save that of cutting and of converting the foliage into Hay."—(Moorcroft in a letter to W. Butterworth Bayley, Esq, formerly Chairman of the Court of Directors.) Various attempts have been made to introduce the Prangos Hay plant into Great Britain, but hitherto unsuccessfully; and it is probable it will only succeed, and be valuable in a climate similar to that where it is found indigenous. The Prangos is highly valued in the cold and arid region of Tibet, where it is indigenous, and which Mr. Moorcroft (v. p. 179) thought would be valuable as fodder for sheep and cattle in European countries. It is found in Tibet, and also most abundantly on Abatoong, a low trap hill in the valley of Cashmere; but there it was not so vigorous as in its Tibetan habitat. Though abundant in various directions, the Cashmerians do not esteem it of any value, and Dr. Falconer is of opinion that its importance has been much over-estimated, in consequence of its being the only food in many of the bleak and barren tracts of Tibet. In Cashmere, where far from a deficiency of herbage, there is actually a superabundance of pasture grasses, it is necessarily much less esteemed. The Prangos will, therefore, most probably be a valuable acquisition only in countries devoid of good natural pasturage, and of which the climate is favourable to its growth.—*Royle. Pro. Res.*

Joint Grass.—This, says Mr. Bonynge, is not a grass that is generally known in India. I never met with it in the South, North-West, or in Bengal. It grows in the Tartar country; generally in the margins of forests, where there may not be too much shade; a forest being partially cleared, it springs up in places where it perhaps never existed before, or if it did, not for centuries past. The grass will run to a length of some fifteen feet, and will rise, if there be any support, five or six feet; if not, will grow up some three or four feet by its own support. It is not a wiry grass: the joints are some six or eight inches long; with four or five blades of grass about the same length growing out from each joint. The joints near the ground are harder and brittle; those near the top, soft and juicy—with a luxuriant termination of soft blades, similar to those from each joint, but are softer and thicker. On my arrival in the country I found there were no cows, goats, or sheep. These I introduced, and at the same time a quantity of gram, upon which sheep are fattened in East India. After the arrival of the cattle they declined the gram, and I found on inquiry that they had been browsing on this

grass, and upon which they continued to feed. They all became as fat as if fed on the gram, (a kind of pulse,) which remained on hand, there being no use for it.—*Bonynge, America, page* 159. The principal of the Indian grasses, and perhaps the most generally diffused, is the Doob-grass (*Cynodon dactylon*), a creeping plant possessing much nourishing property in its long stems, no less than in its leaves. This endures the greatest elevation of temperature, as its roots penetrate far below the surface, and although during the dry monsoon giving no sign of life, it puts forth its tender leaves on the first approach of the rains. A very nourishing grass, possessing a powerful aromatic odour, is met with on the elevated lands above the Ghauts of the south, as well as in the north-west provinces. So strong are its aroma and flavour, that the flesh, milk, and butter of the animals feeding upon it become in time sensibly affected both in taste and smell. Upon the many slopes of the Himalayas there is found abundance of good nourishing pastures, admirably adapted to the requirements of cattle and sheep, and upon which many herds and flocks are reared when the dry season forces them from the plains below. Throughout the flat countries, and spread over vast tracts of indifferent soil, we meet with grasses, or rather herbage, in sufficient abundance, but generally either coarse and poor, or rank and distasteful to animals. In swampy or sterile plains these reedy grasses often fail to tempt even the coarse-feeding buffalo and rhinoceros; and it is a common practice amongst all the Indian villagers, at the end of the dry season, to set fire to these tracts, on which the long withered herbage readily ignites, and after the first monsoon showers furnishes a rapid and abundant supply of young sweet blades. In some parts of India, especially at the Presidencies, it is customary to cut grass for hay, as fodder for horses during the excessively dry months, but latterly artificial grasses have been introduced for this purpose. The Guinea-grass and Mauritius-grass are both admirably adapted for feeding cattle. The grasses so extensively diffused, and in differ- ferbivorous as pasturage for cattle and corn for ing impro sential for the continued existence of table-land, kingdom, are seldom thought of as the frontier prov rdage. Yet they were probably and Saharunpore. es which were converted into malayas, enjoyin le twisting between the hands pean-like veget and pliant stems of many of ellent pastura a rope, as is daily practiced the tempera hose of straw, and the rush- y grasses are formed of the twisted are associa e employed for thatching, gener screen-and-mat-making. ter's ate the presence of fibre tho bear at least a certain ressure. In these plants however, as well as in sedges and rushes, the fibre is not always separated from the rest of the vegetable matter, but the whole leaf or stem is dried, and used in its entire state. As the fibre, however, possesses the requisite degree of tenacity, it can be separated in the form of pulp and used for paper making. The grasses abound in India; in the plains are numerous species of genera little known in Europe; with the cultivation of rice, maize, joar, and many millets in the rainy season; and in the cold weather, of wheat, barley, oats, and millet; while in the Himalayas the pasture-grasses are many of them the same as in Europe, and the cereals are cultivated in the spring and summer, with some rice in the rains. In India several of the indigenous grasses are employed for making mats, baskets, ropes, sacks, nets and sails. Thus the *Moonja* of the natives (*Saccharum munja*) is collected after the rainy season and kept for use, as it is employed in tying up their cattle at night and for ropes for their Persian wheels. It is said also to be one of the grasses employed for making tow-ropes by the boatmen about Benares. The *Shur* or *Sara* of Bengal (*Saccharum sara*), or the Pen reed grass, Mr. Henley informs Dr. Royle is another species employed by the boatmen about Allahabad and Mirzapore, and esteemed as a tow-line for its strength and durability, even when exposed to the action of water. It is said to be beaten into a rude fibre and then twisted into a rope. Besides the above, the sacred grass of the Hindoos, the *dab* or *koosha* of the Brahmins (*Poa cynosuroides*), is also made into rope in North-West India. Other species of Saccharum are used for thatching and for screens, and some for making writing-pens and for arrows. The fibres of the *Khuskhus* or Vetiveyr are more remarkable for agreeable odour than for their tenacity, while the Bamboo, the most gigantic of grasses, might be enumerated with timbers rather than with fibres, though its split stems are often employed for making mats in India, and the young shoots for paper-making by the Chinese. Many others of the grasses might be converted into half-stuff for paper-makers, and have the great advantage of affording large quantities of a cheap material. The *Nul* or *Nar* of Bengal is described as being employed for making the mats known by the name of Durma, which are formed of the stalks split open. Dr. Stocks informed Dr. Royle that in Sindh the grass called *Sur*, which perhaps is *Arundo karka*, has its culms, *sur jo kanee*, made into chairs, and its flower-stalks beaten to form the fibres called *moonyah*. These are made into string or twine (*moonyah jo naree*), and into ropes (*moonyah jo russa*). Mr. Burns, of the Indus Flotilla, has mentioned that the boatmen of the Indus universally employed the Moonja (probably the above *Saccharum Munja*) as a towing rope and for the rigging of their vessels, in all places above Sukkur. But below that place Coir

rope is very generally employed, being better able, it is believed, to stand the action of salt water. The Moonja however, is possessed of great tenacity, as is evident from two-inch ropes, often fifty fathoms in length, made of its fibres, being sufficient for dragging their largest or 1200-maund boats up the Indus, and consequently against the full force of the stream, even round projecting points. The rope is also possessed of lightness, so advantageous for rigging, and is capable, also, of bearing, without injury, alternate exposure to wet and to subsequent drying; both qualities being essential for a tow-rope. Mr. Burns has also informed him that plants growing beyond the range of the overflowings of the river, or of the influence of the tides—that is, in the interior of the country, where, indeed, it grows in vast abundance—are possessed of the greatest strength. The upper leaves, about a foot or so in length, are preferred and collected. Having been made up into bundles, they are kept for use. When required for twisting into rope, they are first moistened in water, two men then, sitting opposite to each other, take one of these moist bundles and beat it alternately with mallets, until the loose cellular are separated from the fibrous parts. These are then ready for twisting into the ropes which are so extensively employed on the Indus. It is evident that a continuation of the same process, or the employment of the *Dhenkee* of India, would afford a very ample supply of half-stuff for paper-makers, and at a cheap rate.—*Royle Ind. Fibres page* 30. Griffith collected nearly one hundred different grasses in the Tenasserim Provinces, but Mr. Mason is not aware that the description of a single species has ever been published.

The Description of Grasses best adapted to different localities. The most nutritious Grass, indigenous to all parts of India, and when cultivated, of most luxuriant growth in the hottest time of the year, is Hurriallee; but as it will take two, or three years, before sufficient hay could be produced to supply each Horse with 3 lbs. a day for six months in every year, it would be a great saving to Government if Rumnah Grass land were allotted to Regiments. Although there are no Rumnahs available at Madras, the Horse of the Body Guard could (with His Lordship the Governor's permission) have the Grass growing in Guindy Park, as it remains untouched by the Antelope, and is fully equal to similar Grass issued to Horses up-country. I do not think Rumnah Grass grows at Bangalore, but as the "Hurriallee" thrives there to perfection I apprehend no difficulty in raising a supply of it at once. The 7th Light Cavalry have purchased no other Forage but *hay* for 1853-54, at 184 lbs. per Rupee, and if it be "Hurriallee," Saugor must be a more congenial climate for it than even Bangalore, where no more than 64 lbs. are obtained for a Rupee.

GRAMINACEÆ OR GRASSES.

The quantity of land required to raise Forage for 100 *Horses.* The produce of Grass will vary at each station, and depend entirely upon the soil and means adopted in its cultivation. I should however suppose—that after the first year four cawnies would yield sufficient hay for the use of 100 Horses, for six months in each year, at 3 lbs. per Horse. A piece of ground about 15 yards square, near the sick Lines of the Body Guard, were dug up, manured, and sown with Hurriallee roots, and without irrigation it produced three cuttings, weighing about 500 lbs. of hay, and Mr. Pritchard expected to get a much larger quantity after the rains this year.

The most advantageous means of cultivating Grass, as regards irrigation, manure, &c., and the proper Agencies to be employed in effecting the object in view with efficiency and economy.—It would be a saving of labour if Grass lands could be allotted near Regimental Wells, from which they could be irrigated, and the water now wasted after watering the Horses could go to supply them—but this I fear will not be practicable at all stations, either from want of ground or a scarcity of water during a very hot season, when some of the Wells become quite dry, or contain scarcely sufficient water for the Horses. No person in India has bestowed so much pains and perseverance in the cultivation of Hurriallee Grass, as Major Ottley, and we cannot do better than transcribe his Report to the Agri-Horticultural Society of Madras, and published in the Madras Journal of Literature for 1849, Vol. XV. Page 477. It is replete with most valuable practical information. Vellore, 17th July 1849. "No one in Vellore besides "myself has ever attempted its cultivation and "for three years I had little success, although, "the ground was dug, cleaned and manured to "the fullest extent, from pits 20 feet square, and "five feet deep of Cow-dung, at least a year old, "and all the watering was to little purpose for "it never exceeded six or 8 inches in height. At "the recommendation of a native, I mixed po-"tash to loosen the soil, but it had the effect of "destroying the roots, and to remedy this, I "covered the whole surface with about 9 inches "of light sandy stuff called wundul, taken from "the bottom of tanks, adding to it plenty of "dung. I planted again and the result was "most favorable. Rice land is clayey, and after "irrigating cracks and is more or less one sheet "of sun burnt brick, which precludes the roots "from bifurcating, or shoots springing up, the "condition of my ground will be best shown by "a return of 8 crops last year of as fine hay, as "can be produced in any part of the world, "averaging one ton a cawny. You have only to "give me 30 days law any month in the hot "season, to furnish a specimen to the extent of "4 tons. I find the roots after a year, get so "thick and matted, that the grass cannot grow

" more than a foot, in fact the upper surface can " only be compared to a coir rug: when this is " the case, it takes three days ploughing to get " rid of the superfluous roots, and although one " would fancy from the cart loads taken out, that " few roots would be left, still, in about 10 days, " with good flourish of manure which is thrown " previous to the last ploughing, it will be found " after levelling, ridges prepared 6 feet apart, and " watering by the pecottah, that the plot is as " green as ever, furnishing a good return, but " still better the second cutting. The dry weather " is more favourable to crops than the monsoons. " Too much wet is bad, and produces frequently, " myriads of caterpillars, that devour all but the " stem in a night or two. I only water twice. " Seed will answer very well, but roots of a pro- " per description throw almost a year in ad- " vance of them. I attempted three modes of " planting, first dibbling, sticking the roots up and " down, but this was too slow a process, so I in- " undated the ground like a paddy field, and " struck them into the mud, but neither plan an- " swers so well as making long furrows with a ma- " moty three or four inches deep, and laying the " whole root in lengthways, for, then every joint " or knot throws out a shoot. and covering them " prepares another trench so that two men cut " along at a great rate; the principal part of my " ground was really good for nothing and " took 12 to 14 men a year to dig and " clear an acre, for it was full of those hor- " rible knotty weeds that have long fibres, " under ground called " cango." I then dug " a number of holes 2 feet deep, 4 in diameter, " 5 feet apart and put into each 2 cart loads of " fresh cowdung, and covered them with wundul " and old manure, and, when the surface was all " properly prepared, and planted, I found that the " grass that grew over the pits to be most luxuri- " ant, when other parts seemed bare in compari- " son, although the produce throughout was splen- " did, this shows that the richer the soil, the bet- " ter the crop. Quicklime as a manure is ad- " mirable stuff; in proof of which I deposited a " cart load on the grass and threw a bamboo " mat over it, in the course of three weeks the " grass grew through the lime and mat, and it " was with force alone it could be removed. " Another experiment was to strew straw over " a bed that had been watered for the last " time and the grass rose much higher than " in parts where it was not applied. In May " and June I had excellent cuttings and the " compound is now like a sheet of paddy, I " take no pains to grow more than is want- " ed for my stud, nevertheless I can accom- " modate my friends with a little. From what " I have offered, it will be observed that it is " quite useless attempting to cultivate this kind " of grass, except in deep, rich, loose, mellow " soil, I manure from large pits that are always

" kept filled with cow dung and the tops cover- " ed with light earth to prevent evaporation " of chemical properties. This is mixed year- " ly with wundul, lime and a sprinkling of salt " and a good layer is spread over the plots, " and ploughed in as before stated, all this ex- " pense is thrown away without you have ca- " pacious wells at convenient positions, say, for " an acre and a half, to irrigate beds that must be " nicely prepared 6 feet broad and 30 long, with " a gentle slope, so that the water may flow over " them quickly, larger beds are only to ensure " loss of time, labor and water, and this bit of " information was taught at a considerable cost, " having had to diminish the size of all the par- " titions, three different times, for I found it took " all day to water the most trifling space, and, by " the means suggested, half an acre can be flood- " ed with a Pecottah and pair of bullocks in 8 " hours. The Bangalore hay is a melange of " all sorts, and I will back my garden against " any in Mysore for quality, quantity and length " of produce, at any season of the year, as I be- " lieve no man in India has ever taken the same " pains to bring this particular grass to perfec- " tion, and that for a period of 5 years. It is no " doubt a description of couch grass, for it is " equally difficult to extirpate, and the roots are " generally found a foot from the surface, and " the smallest particle left in the ground will " shoot up. I return the several papers and am " only sorry I have not had time to consider " the subject in the manner I should wish, so " excuse this hasty reply." (Signed) C. G. Ottley.

The subject of managing grass lands, if taken in its full extent, would far exceed the limits proposed in this Memorandum, in which I shall endeavour to give as briefly as possible, an outline of the various means whereby even the poorest soil may be rendered capable of adding something to the general stock of food necessary for the support of Government Horses and Cattle. Grasses are divided into a very large number of species, and these are extremely various, not only in their nutritive properties, but also in their time of ripening, their seeds, their habits, and the duration of their existence. The majority are annuals, but some of them appear to be perennials. The sum total of described Indian grasses is probably about 1300 species. One hundred and fifty is the number said by Wight and Griffith to have been obtained from the Peninsula of India, but only such as are eaten by cattle are here alluded to, and of these a list is given in Appendix A. In the way of systematic classification, we have as yet no text book for Indian grasses. Several eminent Botanists have commenced the task of arranging them, but either the materials have been insufficient, or life has been cut short before the completion of the work. I believe, however, that a monograph of the subject may shortly be expected from the pen of Colonel Munro, H.

M.'s 39th Regiment; and there is reason to think, from the manner in which Doctor Hooker mentions the work, that the want so long felt will be ably supplied. In this part of India, the vegetation of most plants is interrupted for a longer period by the dry season, than in Europe by the winter. The sandy tracts about Madras remain perfectly arid and parched for a greater part of the year; the dry season extending from March to October, only a little relieved by partial showers during the South West monsoon. This alternation of drought and heat, at one season, and of heavy rains, at another, necessarily precludes the pasture grounds of the Carnatic from attaining the verdant, flourishing condition observable in extra tropical countries: at the same time, however, the temperature of the cold weather admits of the production of a considerable quantity of serviceable grass. In England the subject has received great and deserved attention. In some places, hay grasses are cultivated, in some, those adapted for pasturage or for catchmeadows, while in other localities preference is given to varieties which yield early or late pasturage, or have the recommendation of being suitable to some peculiarity of the soil. In India, however, the subject has received no such minute consideration, although deserving accurate investigation and careful experiment. The pasture lands are every where left to nature: there is generally a right of common pasturage; and there is nothing to prevent the village cattle from roaming at discretion. The first step, therefore, towards the improvement of grass lands must be the establishing and keeping up a strong and sufficient fence.

Laying down Grass.—After the erection of a good fence, the next step to be taken in laying down pasture land, is to prepare, pulverize and clean it, and having brought the ground into good condition to apply manure.

Manure.—With respect to the manure best adapted for increasing grass crops, perhaps stable sweepings and the vegetable mould of decayed leaves mixed half and half, is the most serviceable. It is obvious that where there are mounted corps we can always command a large quantity of stable sweepings for pasture lands, and if care were taken to collect urine, and other drainage of stables and dung hills, this would be found even more efficient than solid manure. The urine should be preserved in tanks, which might be formed at a short distance, and the fluid conveyed in pipes would be found a most useful top-dressing; the tanks should be covered to prevent evaporation, and by applying them towards the end of the rains would be washed in without being carried away. If, however, fertilizers of this description are not procurable in sufficient quantities, recourse must be had to other manures; and the alluvial soil which forms the upper layer at the bottom of tanks will be found to answer well. The best season for the application of manure is just before or during the rains.

Foreign Grasses.—The next question that present itself is that of the introduction of foreign grasses. After consulting all the available records of agricultural experience on this matter, it appears that the best way to obtain good fodder at a moderate cost is to pay attention to the indigenous grasses of the country, which, by irrigation and judicious manuring, may be greatly improved—such grasses being always chosen as are suitable to the soil. The Durva or Hurryallee grass (Cynodon dactylon), unquestionably the best species which India possesses for forage, has been cultivated with great success at Vellore by Major Ottley, who has given an interesting account of this grass in the Madras Journal of Literature and Science, 1849, Vol, XV, p. 477, and a short description of it will be found in Appendix R. In upland districts rye grass and clover grow, and both these exotics, when sown fresh, have been found to answer exceedingly well on the Shervaroy, Pulney, Neilgherry, and Bababoodun Hills. The Guinea grass has been strongly recommended in Bengal.

Inoculating Grass.—In poor soils such as that of the Carnatic, grass seeds do not take so well as in rich land; and there is great difficulty in procuring a good sward. In this case recourse must be had to planting, or, as some call it inoculating grass. This is done by taking pieces of turf from the banks of a river or tank, and spreading them over the land to be laid down, after it has been prepared in the same manner as it would have been to receive the seed. The turf should be taken up in little square pieces, and spread over the surface of the ground, leaving small interspaces between each piece. A stone roller or a wooden beater should then be employed to press them into the ground. In a few days the interspaces will be found to be filled up, and a complete carpet of turf to be formed.

Paring and burning the surface of poor soils.—Before putting down the turf, poor stiff lands must be divided by ditches, ploughed in deep furrows, and exposed as much as possible to the wind and sun. Such soils may with careful culture and irrigation become permanent meadow land, but it is essential to get them into a sound state by most carefully clearing them of nuthgrass and weeds before laying down grass seeds, and subsequently by keeping the land free of coarse grass by hand weeding, Paring and burning the surface have been found useful, and if beneficial in the first instance, the operation may be repeated with advantage.

Conclusion.—The above must be considered only as an outline of the plan to be pursued in the cultivation of grass. It is impossible to predict the cost and probable improvement in each case, as these depend so much on local peculia-

rities. But by beginning, as recommended by Mr. Pritchard, on a small and experimental scale at first, and proceeding cautiously, new modes of lessening expense will be suggested, past errors will be avoided, and certain grounds of calculation will be obtained.—H. F. C. Cleghorn, *Professor of Botany*. The Cynodon Dactylon or Hurryalee Grass, of India, is considered the best for horses. Root creeping through the loose sand, with strong fibres at the nodes. Stem rarely exceeding six inches in height, creeping to a considerable extent, matted, very smooth. Florets, all on one side of the spike-stalk, awnless, purplish, and ranged in two close alternate rows. All the stems which lie near the ground take root, and by this means, though an annual plant, it increases and spreads very wide. It yields abundance of seed, of which small birds are very fond. It has been found very successful to allow the seed to ripen before the hay is cut, as it then propagates itself by seeds, in addition to the runners. This Grass is also found in Great Britain, but in that country its produce and nutritive properties are comparatively insignificant, while here it consititutes ¾ of the pasture. Respecting this Grass, Sir W. Jones observes (As. Res. Vol. 4, P. 242,) "that it is the sweetest and most nutritious pasture for cattle; and its usefulness, added to its beauty, induced the Hindoos, in their earliest ages, to believe that it was the mansion of a benevolent nymph. Even the Veda celebrates it, as in the following text of the A't'harvana: "My Durva, which rose from the water of life, which has a hundred roots and a hundred stems, efface a hundred of my sins, and prolong my existence on earth a hundred years."—*Dr. Cleghorn, Grasses.*

(4149) GRASS CLOTH OR CHINA GRASS CLOTH, is fabricated from the fibre of the Urtica nivea of Linnæus, the Boehmeria nivea of Gaudichaud. Though the beautiful fabric known as China Grass cloth has long been known, it is only in comparatively recent times that it has been ascertained to be manufactured from the fibres of the *Boehmeria Nivea*. It is met with bleached and unbleached. It is extensively used by the Chinese, being woven into narrow pieces and into handkerchiefs; the export being chiefly to India and the United States, many handkerchiefs being sent to the latter country.

(4150) GRASS OIL OF NEMAUR.

Roosa-ka-tel. HIND.

This valuable oil was first brought to notice by Dr. Maxwell in 1824, and was further described by Dr. Forsyth in 1826. The oil is obtained from the grass by distillation; 250 to 300 small bundles of the grass are placed in a boiler, covered with water, and distilled. About a seer of oil is obtained in the receiver. Dr. Forsyth describes it as volatile, extremely pungent, of light straw colour, very transparent, with a peculiar, rich and agreeable odour. Dr. Forsyth adds, that it is very highly esteemed by the wealthy natives for the cure of rheumatism, especially that of the chronic kind; two drachms of the diluted oil are rubbed over the pained part in the heat of the sun or before a fire twice daily. It causes a strong sensation of heat or pricking, lasting for two hours or longer. The natives also regard it as an efficacious remedy in slight colds. They anoint the soles of the feet with the oil, and it is stated that slight diaphoresis is thus produced. See *Trans. Med.* and *Phys. Soc.* iii. p. 219.—*O'Sh. page* 639.

(4151) GRATIOLA MONNIERIA, THYME LEAVED GRATIOLA. Lin.

Neerpirimie. TAM. | Jelabrimmi, SANS.

The jointed root, stalks, leaves and blue bell shaped flowers of this creeping plant, which is of the class Diandria and order Monogynia, are all used in medicine by the native practitioners who consider them as diuretic and aperient, and to be particularly indicated in that species of stoppage of urine which is accompanied with obstinate costiveness.—*Ains. Mat. Med. page* 94.

(4152) GREASE, for Railways. The mixture used by the East Indian Railway for axle-grease is this.

Tallow	50 lb.
Country Soap	20 ,,
Castor Oil	30 ,,
Water about	10 Gallons.

Melt the tallow in a large vessel, cut the soap in slices and put into the water when the latter is warm, when the soap is fully dissolved pour the water containing it into the tallow after which add the castor oil: *immediately* after the latter is added, take the mixture off the fire, and while it is cooling let it be stirred constantly till cool. The mixture may require a little more or less water according to the temperature of the weather.

(4153) GREEN COPPERAS, GREEN VITRIOL, SULPHATE OF IRON.

Sulfate de fer, FR.	latum, Salmartis, LAT.
Schwefelsaures eisen, GER.	Taroosee, MAL.
Heracussis, Hera-tootia, GUS. HIND.	Zunkur madnee, Tootiya-subz, PERS.
Solfato di ferro, IT.	Anna bugdie, TAM.
Ferri sulphas, Ferri Vitrio-	

Green copperas is of great importance in the arts. It is a principal ingredient in dyeing: in the manufacture of ink, and of Prussian blue; it is also used in tanning, painting, medicine, &c. When pure it is considerably transparent, of a fine bright, though not very deep, grass green colour, and of a nauseous astringent taste, accompanied with a kind of sweetness.—*McCulloch. Faulkner.*

(4154) GREEN SHANK. The Indian Green shank, has been separated from *Totanus glottis* by the name *T. glottoides*; and the lat-

ter name is adopted by Mr. Gould for the Greenshank of Australia. Upon comparison of fine specimens from Scotland and Norway with others obtained in the Calcutta provision-bazar, we can discern no difference whatever. The alleged *T. glottoides* is simply the bird in its winter plumage, in which it is less known in Britain than in its summer garb.

(4155) GREWIA, a genus of Plants belonging to the natural order *Tiliaceæ*, so-named in honour of Dr. Grew, celebrated for his work on the anatomy of vegetables. Though the family takes its name from the European genus *Tilia*, its species are distributed chiefly through tropical countries. *Grewia* now consists of upwards of 50 species of moderately-sized trees or shrubs, which have leaves resembling those of the elm, yellow or white flowers, and many of them pleasant-tasted subacid fruit. The calyx consists of 5 coriaceous sepals, which are coloured internally. Petals 5, each provided with a gland or scale at the base, inserted with the numerous stamens into the elevated receptacle; germ superior, generally 2-celled; style single; stigma 4-lobed; drupe with from one to four 1 or 2-seeded small nuts. The species of *Grewia* are found in the tropical islands and the hot parts of the Old World, extending west to the west coast of Africa, and south to the Cape of Good Hope. In India they are common in every part, both in jungly forests and the dry open plains; some of the same species extend from the southern to the most northern parts; a few even ascend the Himalayas to moderate elevations. Species are also found in Arabia and Egypt. The species of *Tiliaceæ* are noted for their mucilaginous properties, as well as for the remarkable tenacity of the inner fibre of their bark, as exemplified in the *Tilia*, or common European lime-tree: that of *Grewia oppositifolia* is employed for making ropes with in the Himalayas; and *G. elastica*, figured by Dr. Royle in 'Illustrations of Himalayan Botany,' t. 22, and called Dhamnoo by the natives, is valued for the strength and elasticity of its wood. Cattle are fed on the leaves of some species, as *G. didyma*, at moderate elevations in the Himalayas. The pleasant-tasted subacid fruit of several species is eaten by the natives of India, but principally used for making sherbet. *Grewia asiatica*, or *phalsa*, is that principally employed and cultivated in their gardens.—*Eng*: *Cyc.* Wight, in Icones, gives Grewia columnaris, 44; hirsuta, 76; *microcos*, 84; oppositifolia, 82; rotundifolia, *scabrophylla*, sclerophylla, 89; ulmifolia, 84; and umbellata, 83. Perhaps there is no tree more generally diffused throughout the Provinces than a species of grewia, whose terminal bunches of flowers may be seen on almost every knoll in the country. At Tavoy, when vessels require spars, they are usually furnished from a small tree which grows on the seaboard, belonging to the genus Grewia.—*Mason.*

(4156) GREWIA ASIATICA. Lin.

Fulsa pullum, Tam. | Fulsa, Hind.

Fulsa is, properly, a Hindoostani word, but is also used by the Tamools: it is the name of a small, pleasant sub-acid fruit of a handsome bush and is much prized by the Mahomedans, who prescribe it to cool the habit in fevers. Cultivated at Ajmeer, both large tree and small bush varieties: the large tree is very beautiful when in new foliage.—*Ainslie, page* 225. *Irvine.* This shrub is generally cultivated in most fruit gardens; it bears a dark purple berry, when ripe, containing one or two small stones. The fruit is generally made into sherbet by pouring boiling water on it, and when cool, adding sugar to the taste. The plants are generally cut down almost to the ground in November, and even the leaves are burnt round the stalks, after which the roots are opened and manured, and watered occasionally, when new shoots spring out, and the fruit is borne near the axilla of each leaf; when of a dark purple, they are ripe and fit for use: grown readily from the seed.—*Riddell.* At the Madras Exhibition of 1855, Dr. Riddell exhibited fibres of the Grewia asiatica, G. tiliæfolia and Maliope grandiflora, but they were coarse and indifferent. Grewia asiatica and G. tiliæfolia both yield a useful bast.

(4157) GREWIA FLORIBUNDA.

Myat-ya, Burm.

A very common tree throughout the Rangoon, Pegu and Tounghoo districts, but scarce in the Prome and Tharawaddy districts. The bark affords a coarse strong fibre, not much employed however by the Burmese. It is a good serviceable timber for all ordinary purposes of house-building. There are three other species of *Grewia*—*G. asiatica* is a large tree like *G. floribunda*, but not so plentiful. The other two kinds are small and comparatively scarce. Wood, white-colored, adapted to every purpose of house-building.—*McClelland.*

(4158) GREWIA HIRSUTA.

Javelliki, Tam.

A shrubby plant; fruit hairy, common in the jungles.—*Jaffrey.*

(4159) GREWIA SALVIFOLIA. The species of Grewia makes good walking sticks. The wood of Grewia salvifolia is also good for the same purpose, and the bark of many species yields good fibres.—*Madras Hort. Gard.* 44.

(4160) GREWIA SPECTABILIS AND G. HOOKERII.

Phet-woon, Burm.

Both very plentiful, and of a quality like the last mentioned. They attain a girth of about three to four feet and grow up tall and remarkably straight. They are found with Teak in the forests of Pegu and Tounghoo. Wood, white-colored, adapted to every purpose of house-building.—*McClelland.*

(4161) GREWIA TILIÆFOLIA.

Sadachoo or chadachy marum, also Thalathee marum, TAM.

A considerable tree, the wood is soft and easily worked, useful for inferior building and common purposes. Said to be unfit for cabinet purposes, for which in appearance it seems well adapted, on account of its hygrometric properties, which causes it to contract and expand, however well seasoned, with every change of the weather. —*Wight.* The wood is used for the same purposes as the Ben teak, for which it is often sold at Calicut.—*McIvor. M. E.*

(4162) GROSSULARIACEÆ, *Currant-Worts*, a natural order of Exogenous Plants, consisting of 2 genera and 95 species. The genera consist of shrubs, either unarmed or spiny. The leaves alternate, lobed, with a planted vernation, often with a membranous edge to the base of the petioles. Flowers in axillary racemes, with bracts at their base, rarely unisexual by abortion; the calyx superior, 4- or 5-parted, regular, coloured, imbricated, or somewhat valvate in æstivation; petals 5, minute-inserted in the throat of the calyx; stamens 5, inserted alternately with the petals, very short; ovary 1-celled, with 2 opposite parietal placentæ, ovules numerous, on short stalks, anatropal, style 2- 3- or 4-cleft. Berry crowned with the remains of the flower, 1-celled, the cell filled with pulp; seeds numerous, suspended among the pulp by long filiform cords, testa externally gelatinous, adhering firmly to the albumen, which is horny; embryo minute, with the radicle next the hilum. Nothwithstanding the great dissimilarity in the appearance of these plants and Indian Figs, the two orders were formerly confounded, and are still accounted by many writers conterminous, chiefly, on account of their both having inferior pulpy fruit and parietal placentæ. They are natives of the mountains, hills, and woods and thickets, of the temperate parts of Europe, Asia, and America, but unknown in Africa. In North America they are particularly abundant, and on the mountains of Northern India they contribute to give a European character to that remarkable region. In the tropics of Asia and the South Sea Islands they occur in the form of *Polyosma*, a genus which derives its name from the excessive fragrance of its flowers. To this order belongs the genus *Ribes*, of which the Gooseberry and Currant are different species. The Black Currant is tonic and stimulant and has fragrant glands upon its leaves and flowers. —*Engl. Cyc.*

(4163) GROUND NUTS, ARACHIS HYPOGÆA, OR HYPOCARPOGEA.

Bhoysing, GUZ. HIND.

Ground nuts are now extensively cultivated in the Concans on account of the oil which they afford. They are occasionally exported to England and France.—*Faulkner.* This very singular plant has frequently been confounded with others, partly through the carelessness of travellers, and by the improper use of names, which tended to mislead and confuse. Its common appellation, the earth-nut, has led to the conclusion that it was a species of nut, such as is known in England under the name of "pig nut," "hawk nut," and "ground nut." This, as well as the "earth chesnut," belongs to totally different genera. On the Continent and in the East Indies a similar confusion had long existed by the appellation of "ground pistachio," which caused the fruit to be confounded with the nut of the tree *Pistacia vera*. Some resemblance, on the other hand, existing between these—as well as from their being eaten by different nations, and used as an article of food, and also for producing oil—rendered the true description still more difficult. Botanists have however, well established the nature and character of all these plants. The Arachis "nut" partakes of the nature of the pea or bean of Europe, and is a low annual plant of the order *Diadelphia decandria* of Linn.; orginally from Africa, but now extensively cultivated in every quarter of the globe. It has been naturalised in Europe, and with the climate of the South of France it may be turned to good account. It has been said to be indigenous in Florida, Peru, Brazil, and Surinam; but the plant may be grown on a light sandy soil, under a moderate heat, equal to that of Italy or the South of France. The class to which it belongs approaches to the pea tribe; but its remarkable difference to this, as to the pulse we know as a bean, is the circumstance of its introducing its fruit or pod—if we may so call it—into the earth, for the purpose of ripening its seed. The Arachis, or earth-nut, has obtained its name from this operation. The flowers, leaves and stems, are produced in the ordinary manner we see in the pea tribe. When the yellow flower has withered and the seed fertilised, there is nothing left but the bare stem which had supported it. This stem, in which is the germ of the future fruit and pod, now grows rapidly in a curved manner, with a tendency to arrive shortly on the surface of the ground, into which it penetrates this now naked stem, and sinks into the earth several inches. It is in this obscure position that the fruit takes its ripened form, and is either gathered from its hiding place or left to the future season, when its time of rising into new existence calls it from what was thought its unnatural position. When mature, it is of a pale yellow color, wrinkled, and forms an oblong pod, sometimes contracted in the middle; it contains generally two seeds. The nuts or peas are a valuable article of food in the tropical parts of Africa, America, and Asia. They are sweetish

and almond-like, and yield an oil, when pressed, not inferior in use and quality to that obtained from the olive. The leaf resembles that of clover, and, like it, affords excellent food for cattle. The cake, after the oil is expressed, forms an excellent manure. The Arachis is usually sown in dry, warm weather, from May to June, and are placed at the distance of eighteen inches from each other. Insects are fond of them; and if the season is cold and unfavorable to them, or the growth retarded, they become musty and bad, or are eaten by insects. The mode of obtaining the oil is nearly the same as for other pulse or seeds; and under favorable circumstances the Arachis will produce half its weight of oil. When heated and pressed the quantity is very considerably increased. This oil is good for every purpose for which olive or almond oil is used. For domestic purposes it is esteemed, and it does not become rancid so quickly as other oils. Experiments have been made on its inflammable properties, and it is proved that the brilliancy of light was superior to that of olive oil, and its durability was likewise proved to be seven minutes per hour beyond the combustion of the best olive oil, with the additional advantage of scarcely any smoke. In Cochin-China and India it is used for lamps. It is known as Bhoe Moong or Moong Phullee in Bengal, and as Japan or Chinese pulse in Java. From China this plant was probably introduced into the continent of India, Ceylon, and the Malayan Archipelago, where it is generally cultivated. In South Carolina the seed is roasted and used as chocolate. The leaves are used medicinally. It is grown in Jamaica, and there called Pindar nut. That the culture of the Arachis in warm climates, or even in a temperate one, under favorable circumstances, should be encouraged, there can be but one opinion. And when it is considered that its qualities are able to supersede that of the olive and the almond, which are but precarious in their crops—to which may be added, that as a plant it is greedily devoured in the green state by cattle—how much may it not serve to assist the new settler in regions of the world which have a climate suited to it. It is known by various local names—such as *mani manoli* by the Spaniards, and has obtained also that of *cacahuete* in some countries. It has the additional term *hypogea* attached to it, which literally signifies subterranean. This is apt to mislead; for the plant grows above ground as other pulse, whereas only its seed and pericarp are inserted, after blooming, into the earth. Hence the better term *hypocarpogea*. It appears to form an important article of cultivation along the whole of the west coast of Africa, and probably on the east coast, on several parts of which it was found by Loureiro ("Flor. Cochin," p. 430). It was doubtless carried from Africa to various parts of equinoctial America, for it is noticed in some of

the early accounts of Peru and Brazil. 800 quarters of this nut were imported into Liverpool from the West Coast of Africa, in 1849, for expressing oil, and about half that quantity in 1850. Eighty to 90 tons of the expressed oil are now annually imported. The seeds contain about 44 per cent. of a clear pale yellow oil, which is largely used in India as food, and for lamps, particularly at Malwa and Bombay, &c. Two varieties are grown in Malacca, the white seed and the brown seed, and also in Java, in the vicinity of sugar plantations; the oil cake being used as manure. It is there known as katjang oil. This plant, which seems to be a native of many parts of Asia, has within the last ten years been much cultivated about Calcutta. The seeds contain abundance of fixed oil, have a faint odour, and very mild agreeable taste; 1,950 parts of seed, separated from their coverings and blanched, give 1,405 of kernels, from which, by cold pressure, 703 parts of oil are procured. The seeds are consumed as a cheap popular luxury, being half roasted, and then eaten with salt. The oil is calculated to serve as an efficient and very cheap substitute for olive oil, for pharmaceutical purposes. It burns with little smoke, with a clear flame, and affords a very full bright light, answering perfectly in Argand lamps. The oil cake affords, also, an excellent food for cattle. The ground nut has of late become of considerable importance as an article of exportation, by English houses; yet more so by French houses at Ghent, Rouen, and Bordeaux; some of whom have contracted with the merchants of the African colonies for large quantities, sending shipping for the cargoes. One house alone contracted for 60,000 bushels in the years 1844 and 1845. This nut oil is so very useful to machinery that the naval steam cruisers on the coast have adopted it. A ground nut oil factory exists in the colony of Sierra Leone; but from the want of steam power and proper machinery, and from bad management, together with the inferior attainments of the African artisan, when compared with the European mechanic, and their facilities in quantity or quality, there is abundant scope for improvement. The price in the colony is 4s. 6d. per gallon. It is capable of being refined so as to answer the purpose of a salad oil; the nut is prolific, and eaten by the natives and Europeans, boiled, roasted, or in its raw state; and frequently introduced at the table as we do the Spanish Barcelona nut at dessert. It grows in the rainy season, and is collected in the dry, and sold in the colony for one shilling to eighteen-pence per bushel, in goods and cash. Form of the nut, long, light shell, contains two kernels covered with a brown rind, when shelled white in appearance. It is a low creeping plant, with yellow flowers; after they drop off, and the pods begin to form, they bury themselves in the earth, where they come to maturity. The pod is

woody and dry, containing from one to three peas, or nuts, as they are called, hence the common names, ground-nut or pea-nut. They require to be parched in an oven before they are eaten, and form a chief article of food in many parts of Africa. From a narrow strip of land, extending about 40 miles northerly from Wilmington (North Carolina), comes nearly the entire quantity of earth nuts (known as pea-nuts) grown in the United States for market. From that tract and immediate vicinity, 80,000 bushels have been carried to Wilmington market in one year. The plant has somewhat the appearance of the dwarf garden-pea, though more bushy. It is cultivated in hills. The pea grows on tendrils, which put out from the plant and take root in the earth, where the nut is produced and ripened. The fruit is picked from the root by hand, and the vines are a favorite food for horses, mules, and cattle. From 30 to 80 bushels are produced on an acre. There are some planters who raise from 1,000 to 1,500 bushels a year.—("Hunt's Merchant's Magazine," vol. xv., p. 426.) The ground-nut is exceedingly prolific, and requires but little care and attention to its culture, while the oil extracted from it is quite equal to that yielded by the olive. Almost any kind of soil being adapted for it, nothing can be more simple than its management. All that is required is the soil to be turned over and the seed sown in drills like potatoes; after it begins to shoot it may be earthed with a hoe or plough. In many parts of Western Australia they are now grown in gardens for feeding pigs, the rich oil they are capable of yielding being entirely overlooked. In regard to their marketable value at home, Mr. Simmonds gives a copy of a letter of a friend received from some London brokers, largely engaged in the African trade:—"Wilson and Rose present compliments to Mr. N., and beg to inform him the price of African ground nuts is as under:—Say for River Gambia, £11 per ton here. Say for Sierra Leone, £10 per ton here. For ground nuts free on board at the former port, £8 per ton is demanded; these are the finest description of nut, the freight would be about £4 per ton; the weight per bushel imperial measure, and in the shell, is about 25 lbs." The following, also, is an extract from a letter written in 1842, by Mr. Forster (the present M.P. for Berwick), an eminent African merchant. Speaking of the staple of Africa, he says:—"I have lately been attempting to obtain other oils from the coast, and it was only yesterday I received from the hands of the oil presser the result of my most recent experiment on the ground nut, which I am happy to say is encouraging. I send you a sample of the oil extracted from them. They are from the Gambia. It is a pure golden colored oil, with a pleasant flavor, free from the frequent rancidity of olive oil." Since then the cultivation has gone on, and the exportation largely increased. The French also have entered into the trade, and several vessels are exclusively employed in exporting this product from the river Gambia, conveying it to oil factors on the continent, who extract its oil. Seeing then, the many advantages the cultivation of such a product bestows, and its adaptation to the soil and climate of Australia, I cannot refrain from expressing a hope that some of the influential landowners in the cultivated districts will give the matter their consideration. I am informed by an American merchant that he cleared 12,000 dollars in one year, on the single article of ground or pea nuts obtained from Africa. Strange as it may appear, nearly all these nuts are transhipped to France, where they command a ready sale; are there converted into oil, and thence find their way over the world in the shape of olive oil; the skill of the French chemists enabling them to imitate the real Lucca and Florence oil, so as to deceive the nicest judges. Indeed, the oil from the pea nuts possesses a sweetness and delicacy that cannot be surpassed. Advices from the West Coast of Africa to the 16th August, 1853, report that the ground nut season had closed; the quantity shipped during the season having exceeded 900,000 bushels. The yield has increased 20 per cent. each year for the last three years, and it is expected the increase will be still greater in the forthcoming season.—*Simmonds' Com. Pro. page.* 517.

(4164) GROUND NUT OIL, ARACHIS HYPOGEA. Manilla nut oil.

Vayreuddala-yennai, TAM.	Phullie-ka tael, HIND.
Manilla noona, TEL.	Boysing ka teil, HIND.
Willayetie-moong-kie-	

This valuable oil, which of late years has been exported to a large amount, is obtained by expression from the seeds of the Ground or Manilla nut, which is now cultivated to a considerable extent in most parts of the Peninsula of India. In the year 1848-49—37,000 gallons were shipped, but in the two following years the Exports exceeded 1,00,000 gallons. It has however fallen to 57,207 gallons in 1852-53. It does not seem to be consumed to any large extent in this country, although the nut itself is much eaten by the poorer classes. It is said to be used for adulterating gingely oil in North Arcot, where it costs from Rs. 1-8-0, to 2-12-0, per maund. In the Nellore District, the seeds are procurable at Rs. 1-8-0, per maund and in Tanjore about 200 acres are cultivated, producing annually 75 candies of oil at Rs. 2-6-0 per maund. The seeds yield about 43 per cent, of a clear straw coloured edible oil, which is an excellent substitute for olive oil, and makes a good soap. Its value in London in January 1855 was £47-10 per ton. The Madras Tariff, the Tanjore Local Committee and Lieut. Hawkes exhibit excellent specimens.—*Eng. Cyc.*

(4165) GROUND RATANS. The excellent walking sticks known to the English under this name, are made from the Rhapis flabelliformis which grows in Lin kin and Southern China.

(4166) GRINDSTONES. The Natives of India prepare a grindstone composed of shell lac as its basis, and corundum powder or other hard mineral as the grinding material. In Coimbatore persons of the barber caste are the manufacturers of these. The process is sufficiently rude. The stone being pounded and reduced to the form of fine grained gun powder is heated in a chatty. The lac is then added and the two stirred together until the mass is of the consistence of dough, when it is turned out and beat and kneaded into the required shape. There are only two articles used in its construction, but not using a mould, the operation is tedious and the finished article when completed, not by any means of first rate excellence. The principal objection to them seems to be the extreme hardness which renders them less effective than if the lac by a small admixture of a softer substance were rendered somewhat more yielding. Upon the whole as made there it is a rather rude but durable machine. It was stated that at the Hoonsoor farm, where pearl barley is prepared, English grind-stones for making it required frequent renewal, but that one of this description has now been in use 5 years. The stone used in Coimbatore is powdered coarse garnet sand, found in the beds of the neighbouring hill streams. The Corundum stones met with for sale in the bazars are usually small, generally more rounded and water worn on the edges, as if collected in the beds of mountain streams from among the pebbles they bring down. In making a Lac grind-stone simply of Gum Lac, and finely pulverized corundum stone, these are heated separately to facilitate their more perfect admixture and combination. They are then thrown into a mould and strongly beaten and kneaded to give compactness and expel all air bubbles.—*M. C.*

(4167) GRISLEA, a genus of tropical Plants belonging to the natural order *Lythraceæ*, or *Salicariaceæ*. The genus is characterised by having a tubular calyx, which is from 4- to 6-toothed; the petals, 4 to 6 in number, are inserted between the divisions of the calyx; the stamens, twice as many, arise from the bottom of the calyx, and have their long filaments extending with the style beyond its tube; the capsule is superior, 2-celled, many-seeded, and covered by the persistent calyx. The plants of this genus consist of shrubs, with opposite, very entire leaves, dotted on the under surface with dark-coloured glands. The peduncles are axillary and many-flowered; the flowers reddish-coloured. The species are not more than three in number, of which one, *G. secunda*, is found in the warmer parts of South America, and the others in India. *G. tomentosa*, the best known and most useful species, is found in the islands of the Indian Ocean, in China, and in every part of the continent of India, especially in the jungly tracts at the foot of its several ranges of mountains. In such situations its bright red calyx, retaining its colour till the seeds are ripe, gives the whole plant a very showy appearance, and points it out to the collectors of its flowers, which form an article of commerce. These are much employed by the natives of India for dyeing a red colour, and, having some degree of astringency, are also employed in Indian medicine. The plant is known by the names of Dharee, Dhaee, &c., and the flowers by that of Dhaeephool.—*Eng. Cyc.*

(4168) GRISLEA TOMENTOSA, Woolly Grislea.

Dhawn Phool, Hind.

Very ornamental both in foliage and blossom. The flowers are used in dyeing. This tree would do well in compounds. This is very distinct from the Dhan, which is the common firewood of Ajmeer. Though a rare tree in Ajmeer, the plant is very common in the Prome district, and flowers in April. It is not found in Tounghoo district. —*McClelland.* The red flowers of this plant are used for red dye. In the bazars of Bengal they are found in a dry state, under the name of Datoke. The petals are officinal at Lahore, where they are used as a dye, as well as a medicine. The red petals, contain much tannic acid. —*O'Shaughnessy.* These scarlet flowers generally come to Ajmere, from Kotah and Harowtie: are considered stimulating and given to women in labour. One seer costs four annas. The gum of this tree, called *dhaura* or *dhau ka gond*, is brought from Mewar and Harowtee, and is abundant, white in colour, like the katira and tragacanth gums, swells in water: in dying cloth it is applied to those parts that the dye is not wished to touch; it is eaten in "luddoo:" one maund costs ten rupees.—*Gen. Med. Top. p.* 133.

(4169) GUAIACUM OFFICINALE, Lignum Vitæ.

Gayac, Boissaint, Fr.	Lignum Vitæ, Lat.
Pockhaln, Ger.	Guayaco, Sp.
Guajaco, It.	

A lofty tree, a native of Jamaica and Hispaniola. Both the bark and wood are used as sudorifics in the treatment of gout, rheumatism, and chronic or secondary syphilis. It is asserted that a native of St. Domingo first made known to Europeans the sudorific virtues of this tree. The wood from its extreme hardness is much used for screws, presses, blocks, and pullies. The trunk of the guaiac tree is from 60 feet upward; in temperate climates the growth is exceedingly slow, not more than one line annually. The resin is obtained either by spontaneous exudation, or by taking a billet of wood with a

hole bored through its centre lengthwise, and setting fire to the upper end—the melted resin flows along the tube to a receiver placed beneath it. Internally taken, either wood or resin excites a sensation of warmth in the stomach, and dryness of the mouth and throat (Duncan). It increases the heat of the skin, accelerates the pulse, and proves diaphoretic, if the patient be kept warm, or diuretic, if the surface of the body is exposed to the air. In large doses Dr. Duncan says it acts as a purgative. Besides the diseases before mentioned, guaiac is given in cases of foul ulcers, hospital gangrene, thickened ligaments, mercurial ulcerations, and in various forms of scrofula. The wood is used in decoction, the resin in pills, emulsion, or tincture; 10 to 30 grs. may be given daily. Dr. Duncan states that half an ounce of the tincture with three ounces of water is a sudorific dose for an adult, if he attend to keep himself warm.—*O'Shaughnessy.* The wood is the weightiest timber known; is exceedingly hard and difficult to work; is externally of a blackish brown, and internally of a yellowish colour. It is well adapted for stampers and mallets, for friction rollers, castors, turnery ware: also for the sheaves of pulleys or blocks, a purpose for which it is extensively used. This wood is imported into Bombay from England, and is chiefly worked into sheaves for blocks.—*Faulkner.* This shrub has been lately introduced, into Madras and is found to thrive remarkably well, readily flowering and fruiting. In time, a supply may be available.

(4170) GUANA: IGUANA.

Zib, Arab. | Oodomboo, Tam.
Ghore-pore, Duk. | Oodoomoo, Tel.
Ghoda-sala, Sans.

The Guana of India is generally found about old walls, and ruinous buildings; it is about two feet long; the belly is protuberent; the tail long, round, and tapering: its back, tail, and throat are serrated; and its whole surface is covered with shining scales. The flesh is eaten by the Mahomedans of India, and in the West Indies, it is salted and barrelled for exportation. In India the body of the dried Guana is made into an electuary, with a certain portion of Ghee, and used as a strengthening medicine in consumptive complaints.—*Faulkner.* An animal oil is obtained from it.

(4171) GUANO, Huano. A highly concentrated manure, said to be an accumulation of the excrement of herons, flamands, and other birds, inhabiting the islands of Chinche, near Pisco, the coasts of Peru and Africa, &c. Different opinions, however, are entertained as to its exact nature and origin, many supposing that it is a peculiar mineral or earth. It is a dark yellow substance, of a strong odour, found in deposits of 50 or 60 feet thick and of considerable extent in the localities above mentioned.—*Faulkner.*

(4172) GUAREA TRICHILIOIDES. Bark a violent emetic and purgative.—*O'Shaughnessy, page* 346. Wight in Icones, gives G. Paniculata.

(4173) GUATTERIA CERASOIDES. *Anonaceæ*, Roxburgh C. 33. A moderate sized tree, wood white and close grained, at least as seen in a three or four years old branch. Dr. Wight had not seen it as it appears in the trunk.—*Wight.*

(4174) GUATTERIA LONGIFOLIA.

Thavathroo, Tam. | Asoka chettoo, Tel.

A very handsome, erect growing tree, wood soft and useless.—*M. E. of* 1855,

(4175) GUAVA TREE, White and Red, Psidium Pomiferum, Lin. P. Pyriferum.

Coia murum, Tam.

The wood of this tree, from being extremely close grained, tough, and compact, is preferred for making wooden mallets, and other things required to stand hard knocks.—*Ains. Met Med. page* 211. It is also used for wood engravings. In Tenasserim, the guava is planted perhaps more extensively than any other fruit tree in the country. Loudon has the most correct notion of the fruit. He says: "Most of the species are cultivated in the tropics for their fruit, which also ripens freely in this country, but is of little merit." The white guava is the species most usually cultivated but the red is not uncommon.—*Mason.*

(4176) GUAZUMA. A genus of the family Byttneriaceæ, the G. ulmifolia sometimes known as Bastard cedar Gunstock-tree introduced into Madras from South America and the G. tomentosa. G. ulmifolia presents, between its outer bark of sapwood—a fibrous mass about half an inch in thickness, richly impregnated with mucilage, which is extracted by macerating the fibrous mass, for twelve hours, in warm water, and is greatly employed in the West Indies for clarifying sugar. G. Tomentosa yields fibres. This Guazuma is employed in South America in clarifying sugar, as a Kydia is in India.—*Royle.*

(4177) GUAZUMA TOMENTOSA, K. (Abroma Guazuma, Willd). A native of South America and of the West Indies, and now common in gardens in India, where the wood is called the bastard cedar; the old bark is used in the West Indies as a sudorific; the young bark is very mucilaginous, employed for clearing sugar. The bark of the *Kydia calycina* (*Choupullea*, Hind.) a native of Coromandel, Nepal, and the Neilgherries, is used for the same purpose in this country.—*O'Shaughnessy, p.* 226. In the Dekhan it is rather a common tree, with small yellow axillary and terminal flowers, capsule woody, tubercled, about the size of a small plum.—*Riddell.* The tree is pretty common about Madras, evidently planted, the fruit is tubercled, about the size of a cherry, introduced by Dr. Anderson about 70 years ago.—*M. E. J. R.*

(4178) GUAZUMA ULMIFOLIA is a South American tree, which was introduced into India, and largely cultivated at one time in the Madras Presidency under the name of Bastard Cedar, as fodder for cattle. The fibres of its straight, luxuriant, young branches were submitted to trial by Dr. Roxburgh. The Byttneria Tribe, of plants to which this genus belongs, are by some botanists considered a distinct natural order, by others reduced to a section of Sterculiaceæ. They belong to Lindley's Malval alliance of Exogens, and are readily known by their petals being bagged at the base, their stamens partly sterile and petaloid, and their fruit covered with hooked spiny hairs. From Sterculiaceæ proper they differ by the presence of petals, and their stamens not being united into a column; from Malvaceæ by their 2-celled anthers and bagged petals; and from *Lasiopetaleæ* by their calyx not being coloured like a corolla, and their petals not rudimentary. The species are chiefly inhabitants of tropical countries. They partake of the mucilaginous inert properties of *Malvaceæ*. Their bark often yields a tough fibre fit for manufacture into cordage; and one species, *Theobroma cacao*, produces the seeds from which the buttery and somewhat bitter substance called cocoa is obtained, and which forms the basis of chocolate. The fruit of *Guazuma ulmifolia* is eaten by the Brazilians. Many of the species yield fibres which might be manufactured into cordage, as *Microlæna spectabilis* and *Abroma augustum*.

(4179) GUETTARDA SPECIOSA, Rubiaceæ. Lin.

Panneer poo, Tam.	Panneer poo, Tel.
Panneer ka pool, Duk.	Hima, Sans.—*Ainslie.*

A small tree: with large white fragrant flowers, in blossom throughout the year: the tree is sacred both to Siva and Vishnoo.—*Riddell.* Is extremely fragrant: Corals white and tube long. The tree itself is very handsome. *Ain.'s Mat. Med. p.* 158.

(4180) GUGAL KA GOND, Amyris agallocha. The tree is plentiful in the Ajmeer hills, yields a fragrant gum resin used in the sacred fumigations by the brahmins; the gum has a similarity to myrrh; used also in flatulencies taken in ghee: is one of the ingredients in the incense or "dhoop."—*Gen. Med. Top. p.* 135.

(4181) GUIA KHUTAI. A Bokharian Hakim presented Dr. Bonigberger with a hard, pitch-like plaster (on a small piece of red linen), which he pretended had been prepared in China, and which was capable of removing every kind of pain, simply by application. One and the same plaster serves for several cases. The form is square, three or four inches in diameter; each of them bears a Chinese Seal. According to the assertion of the Hakim its constituent parts are sweet oil and litharge, the latter, as an impalpable powder, is added to the former. The Bokharian doctor pretended that every pain without exception, must yield to its application. It should be applied as near as possible to the affected part; for instance, in headache, it ought to be applied on both temples or on the forehead, in ear-ache behind the ears; in carious toothache a small piece should be put into the hollow of the tooth. It acts as a rubefacient, without blistering.—*Dr. Honigberger, page* 282.

(4182) GUINEA GRASS. Panicum jumentosum. Guinea grass is grown by a few Europeans in Tenasserim, and it does as well as the indigenous species. See Grasses.

(4183) GUIZOTIA OLEIFERA. Verbisina sativa.

Ramtill, Hind.	Valasaloo, Tel.
Oochelloo. Tam.	

A seed equal to the shape of Black cummin seeds has no smell but oil manufactured from it.

The Oil.

Valeesaloo Noonay, Tel.	Kala Till-ka-tel, Hind.

This sweet tasted edible oil is plentiful in the Mysore, Vizagapatam and Ganjam Districts. It is used for nearly the same purposes as the Sesamum. It is procurable in the Nuggur Division of Mysore at Rs. 3 8 0 per maund, but is considered inferior to gingely oil.—*M. E. of* 1855.

(4184) GUJ PIPPUL. Fruit of Pothos officinalis. Guj-pipar, according to Dr. Irvine, is supposed to be the root of Borassus flabelliformis, brought from Cabul: is astringent, and is given in medicine, to promote digestion: one seer costs two rupees. The guj peepul or guj-pipar is the sliced dried fruit of Pothos officinalis.—*Genl. Med. Top. page* 135.

(4185) GUILANDINA BONDUCELLA: KUTKULINGA. East and West Indies; commoner in Bengal than Madras. The kernels are very bitter. Mr. Piddington has detected in the nuts oil, starch, sugar, and resin; further analysis is desirable. This substance is the commonest antiperiodic supplied in the list of Bazar medicines to hospitals in Bengal, and it is undoubtedly one of considerable utility, especially in convalescence from fever: I cannot speak of its qualities from any accurate observation, although like others I have used it a good deal among sepoys and jail prisoners with apparent benefit. Mr. Waring thinks but poorly of it. But many think differently and sub Assistant Surgeon Bholanath Doss of Ajmeer says a few doses of it with black pepper were sufficient to put a stop to the paroxysm. He sometimes gave 12 to 15 grs. three times during the day, at other times he gave 8 grs. every hour, leaving it off an hour, before the expected paroxysm. If it does not stop the paroxysm the first time it seldom fails the second. The common way of exhibiting this substance is to give of the nut finely powdered, and of black

pepper, each 6 to 20 grs. three times daily.—*Ind. Ann. Med. Sci. for April 1856, page 192.*

(4186) GULANCHA. Root and stem of Menispermum cordifolium; intensely bitter, transverse section very porous and radiated.—*O'Shaughnessy, Beng. Ph.*

(4187) GUL-GAJUBA. Flowers of gajuba from Bombay: cooling, in various mixed prescriptions: one seer costs two and a half rupees.—*Gen. Med. Top. p.* 136.

(4188) GULPISTA.

Buzgund. Guz. and Hind.; Gulpista, Pers.

A kind of gall produced on the Pistachio tree (*Pistacia vera*), a native of the South of Europe, and of Asia. They are imported into Bombay from the Persian Gulf, and are used in medicine by the natives of India.—*Faulkner.*

(4189) GUM TRAGACANTH, Gum Dragon.

Samagul-kateera, [illegible], Arab.	Kattera, Guz. and Hind.
Gommi astraganti, Fr.	Tragacantha, Lat.
Traganth, Ger.	Vadomocottay pisin, Tam.

A gum produced by a species of *Astragalus*, growing in Persia and Turkey. It is more costly than, and extremely different in many of its properties from Gum Arabic. The finest kind occurs in twisted, vermicular, rounded or elongated pieces, almost transparent, whitish, brittle, inodorous, with a slightly bitter taste. It is also found in large tears, of a vermicular form, a reddish colour, and mixed with impurities. It is used in topical dyeing, and in pharmacy for making powders into troches, &c.—*Waterston. Faulkner.*

(4190) GUM AMMONIAC.

Feshook, Ushek. Arab.	Ammoniacum, Lat.
Gomma Ammoniaque, Fr.	Semuugh-bil-Shereen, Pers.
Ammoniack, Ger.	Goma Ammoniaco. Sp.
Astruck, Guz. Hind.	
Gomma Ammoniaco, It.	

A concrete resinous juice obtained from a plant resembling fennel, found in the north of Africa, Arabia, Persia, the East Indies, &c. It has a bad and peculiar smell, and a bitter, nauseous, sweet, taste. The colour externally is yellow, and white internally. It is imported into Bombay from the Persian Gulf, and is chiefly re-exported to England. It is used in medicine.—*Faulk.*

(4191) GUM ARABIC.

Samagh Arabee, Tolh, Arab.	Arabee Goondur, Guz. Hind.
Gomme Arabique, Fr.	Gomma Arabica, It.
Arabische Gummi, Ger.	Kapitha, Sans.

Acacia, L. Gummi Acaciæ, E. Gummi Arabicum, D. Gum of various species of Acacia E., of A. vera, *Willd.* L.; of A. vera and A. arabica, D. Gum Acacia or Gum Arabic. Gum being an exudation from many trees, especially in warm and dry climates, must have been known from the most remote antiquity; and hence we find it mentioned by early Greek writers. It probably formed an article of commerce from Africa into Europe in ancient as it does in modern times. Gum being required for use in the arts as well as in medicine, large quantities are imported from the west and the east coast of Africa, from Egypt, Arabia, India, New Holland, and from the Cape of Good Hope. *Gum Arabic*, so called from being supposed to be produced in Arabia, is imported in immense quantities from Africa into Aden; none is collected and very little produced in Arabia. (Malcolmson.) It used to be produced in Upper Egypt and Nubia. M. Pallme describes the gum as being collected in Kordofan, especially in the district of Bara, in November, December, and January, it "is of the finest quality, and is erroneously named Gum Arabic;" from 10 to 14,000 hundred weight being conveyed on camels from Bara to Dongola on the Nile, whence it is conveyed to Cairo, and thence distributed to Europe. As the whole of the arid desert country is covered with Acacia trees, much is also conveyed to the ports of the Red Sea, and from thence to the opposite coast of Arabia, whence it is re-exported to Bombay, and from thence to this country. This is probably yielded partly by the *Acacia vera* and *A. arabica* mentioned in the Pharmacopœias, but chiefly by *A. Seyal*, *A. Ehrenbergii*, and *A. tortilis*. M. Pallme says that the Gum-tree of Kordofan differs materially in the shape of the tree, its leaves, and spines, from the Mimosa nilotica, that is, *Acacia vera*. Mr. Johnston, when near the Hawash, had given to him a lump of soft Gum Arabic, nearly a pound in weight, and of most agreeable flavour, like a green ear of corn. He mentions at the same time, that the trees were without exception the long-thorned Mimosa, and tall enough to ride under. It was probably the A. tortilis or A. Seyal. *Gum Senegal* is exported from Portendic, Sierra Leone, and the French settlements on the Senegal, being produced chiefly in the desert country to the north of the Senegal. *Acacia Verec* is stated by the authors of the Fl. de Senegambie to yield the pale and fine varieties, *A. albida* (*A. Senegal*, Wild.), and *A. Adansonii* the inferior reddish varieties. *A. Seyal*, *A. vera* and *A. arabica*, being found in Senegambia, probably also yield some of the gum exported from the western coast. *Barbary Gum* is exported from Mogador on the west coast of Africa, and is produced in a similar kind of country. It is an inferior kind, and, moreover, a mixture of two or three kinds. *Acacia gummifera* is thought to yield some of this gum. Jackson gives *attalet* as the name of the tree which produces gum. *East India Gum* is exported to Europe chiefly from Bombay, having been previously conveyed there from the coast of Arabia; so that it is chiefly of African origin. But some of Indian origin is also exported from

Calcutta by the name of Babool Gum, which is that of the *Acacia arabica*, and is of good quality, but Gum is yielded also by *Acacia serissa* and *A.* now *Vachelia farnesiana*, also by species of other genera. Gum is also imported from the Cape of Good Hope, yielded by *Acacia karroo*; and *A. decurrens* yields gum in New Holland. As space cannot be afforded for all, we will restrict ourselves to the description of the officinal species. ACACIA VERA. Willd. (*Mimosa nilotica*, Linn) A middling sized tree, with spines in pairs, straight, sharp, about a quarter to half an inch long. Leaves bipinnate, and as well as the branches smooth; these are covered with a reddish brown bark. Two pairs of pinnæ. Leaflets small, 8 to 10 pairs, oblong linear, with a gland between the pinnæ. Flowers in yellow, globose heads, from 2 to 5 in the axillæ of the leaves, and stalked. The legume is moniliform, short, straight and containing but few seeds. A native of Egypt and extending across Africa to Senegal. An astringent extract, known to the ancients by the name of ακακια, was prepared from the legumes of this and probably of other species. Dr. Royle obtained it in the bazars of India by the old name of *akakia*. ACACIA ARABICA. Willd. (*A. nilotica*, Delil.) Usually only a small, but growing to a tree 40 feet in height. Spines in pairs, usually short. Leaves bipinnate, with 4 to 6 pairs of pinnæ, with a gland between the first and between the last pairs. Leaflets from 10 to 20 pairs, minute, oblong, smooth. Flowers yellow, fragrant, in globose stalked heads, axillary and subternate. Legume stalked, moniliform, long and curved, compressed, contracted on both sutures between each seed. A native of Egypt, extending across Africa to the Senegal; found in Arabia and in every part of India.—*Roxb. Com. Pl.* II. t. 149. Gum, dissolved in water or in the form of a mucilage, is a very generally diffused principle of vegetables. It flows from the several Acacias in a liquid state, but soon hardens, and may be seen from a perfectly colourless substance to different shades of yellow, even on the same tree. It is in dry, semitransparent, roundish masses, of the size of a small nut, or larger, often in fragments, rugose at the surface, brittle, friable; fracture vitreous; without odour; of a mild, slightly sweetish, viscous taste. Sp. G. about 1·31 to 1·52. It is soluble in water, having a slightly acid reaction on litmus. The finer species are often separated after being imported, and form the picked or Turkey Gum; the inferior kinds are in larger or irregular pieces, of a deeper colour, more mixed with impurities, and less soluble. *Adulterations.* The inferior kinds of Gum are apt to be intermixed with the finer kinds of African Gum, especially when powdered; but in this state, starch also is apt to be added, but may be detected with Iodine. The following observations occur in the Juries' Reports of the Madras Exhibition of 1855. The term *Gum* properly speaking, is confined to those natural exudations, which solidify on exposure to the air, but are easily redissolved by water: they are often transparent, but vary in tint from white to reddish brown. Of the true gums, the only one which enters largely into commerce from the Madras Presidency is *Gum Arabic*, or East Indian gum: under this term, the exudation of a variety of trees is known to be included, and the variation in quality of many of the specimens is very remarkable. When insoluble in water, but soluble in alcohol, these exudations bear the name of *Gum Resins*, they are chiefly used in medicine. When soluble in spirit of turpentine, they are *Resins*, these are used for the most part in preparing dyes, varnishes, lacquers, sealing wax, &c. &c. Besides these two sorts, the *Elastic Gums* belong to this section. India rubber and Caoutchouc are the types of the latter, both of these substances rapidly rose in demand after their first discovery, and merchants anxiously look for new sources of supply. Recent inquiry has shown that caoutchouc is furnished of good quality, by a large number of milky juiced plants, belonging to different families (Sapotaceæ, Apocynaceæ, Moraceæ and Euporbiaceæ.) Assam, in particular, furnishes large quantities of India rubber from "*Ficus elastica*," whilst specimens are exhibited from Labuan of the "*Urceola elastica*" caoutchouc, and from the Peninsula of *Cryptostegia grandi-flora*. On the other hand, the supply of Gutta Percha from the Indian Archipelago is beginning to fall off. By a late account, a few isolated trees here and there occur, but they are scarce and Gutta Taban (as it is there commonly called,) will every year be more difficult to obtain, as the coast region is said to be pretty well cleared, and a long transport from the interior must, by augmenting the labour, increase the value of the article. Up to 1844, it was calculated by Mr. Logan, in the "Journal of the Indian Archipelago," that 270,000 trees had been felled—value of gutta percha 274,190 dollars —the value of each tree is thus on an average about a dollar. The difference in the appearance and properties of the gutta percha of the present day, is owing to its having become a manufactured substance with an intermixture of inferior guttas, added by the gum hunters to increase the weight.—*M. E. J. R.*

(4192) GUM, GHAUTTY OR INDIAN GUM; BABOOL GUM.

Ghautty Goond, GUZ. and HIND.

A substance, the produce of the Babool (which furnishes most of the gum found in the bazars), the Nim, Mango, Cotton, Wood-apple, and several other trees. This gum is not unfrequently mixed with, or substituted for, Gum Arabic. It can, however, be easily distinguished from Gum Arabic by its being more brittle

and less adhesive and gummy, and generally in smaller pieces. The trees which produce this gum, grow abundantly in the Deccan, from whence it is brought to Bombay, and exported to England.—*Faulkner*. The chief Gum Trees &c. of Southern Asia are:

Babool Tumma Gum, ...	(Acacia arabica).
Tangedu jigata, ...	(Cassia auriculata).
Kut or Kheir gum, ...	Acacia catechu.
Dirisana gum, ...	„ Sirissa.
Konda tanjedu jigata, ...	(Acacia xylocarpa).
Mutty pal.	Ailanthus Malabaricus.
Kalabanda jigata, ...	(Aloe perfoliata.
Meisakshi, ...	Amyris commiphora.
Cashew gum, ...	Anacardium occidentale.
Jilledu jigata, ...	(Calotropis gigantea).
Myrrh (inoor), ...	Balsamodendron myrrha.
Bdellium (googul), ...	Balsamodendron.
Olibanum (saleh gond), ...	Boswellia thurifera.
Boorooga gum, ...	Bombax malabaricum.
Pulas gum, Modugu gum, ..	Butea frondosa,
Palay caoutchouc, ...	Cryptostegia grandiflora.
Kuttimundoo, ...	Euphorbia kuttimundoo.
Wood apple gum, ...	Feronia elephantum.
Caoutchouc, ...	Ficus elastica.
Marri jigata, ...	Ficus indica.
Atti or medi jigata, ...	Ficus racemosa.
Dekamunnee, ...	Gardenia lucida.
Gamboge, ...	Gardenia pictoria.
Gutta percha, ...	Isonandra gutta.
Pachonthee, ...	Isonandra.
Vutta thamara	Macaranga indica.
Mamidi jigata	Mangifera indica.
Pogada jigata, ...	Mimusops elengi.
Moringa gum, ...	Moringa pterygosperma.
Assafœtida (hing), ...	Narthex assafœtida.
Devadaru jigata, ...	Phyllanthus turbinatus.
Kino, ...	Pterocarpus marsupium.
Somida jigata, ...	Swietenia febrifuga
Neredu jigata, ...	Syzygium jambolanum.
Gambier, ...	Uncaria Gambir.
Keekur gum, ...	Vachelia farnesiana.

Resins and Gum Elastics.

Amber, Kahroba, ...	Cutch, Assam and Kemaon.
Animi, ...	Bombay, from Africa.
Benzoin, Loban, ...	Straits, Sumatra.
„ a kind of, ...	Malabar.
Caoutchouc, ...	Ficus Elastica, Assam.
Copal, Soondroos, ...	Vateria Indica, Canara.
Dammer, Ral and Dhoonia,	Shorea robusta, Balasore, foot of Himalaya.
Deodar Oil, Kelon-ka-tel, Guggilam, ...	Cedrus Deodara, Himalayas.
Gutta Percha, ...	Isonandra, Singapore.
Mastic, Mustajee, ...	Bombay.
Mysakshi, ...	
Piney, Pandum, ...	Vateria Indica, Canara.
Resin, ...	Beerbhoom.
Theetsee, ...	Melanorrhœa usitata, Assam.
Turpentine, Gunda Biroza,	Pinus longifolia, Seharunpore.
Wood Oil, Gurjun, Dhoona-tel, ...	Dipterocarpus Turbinatus, &c., Chittagong.

(4193) GUM.

Gomme, Fr. | Gomma, It.
Gummi, Ger. | Goma, Sp.
Goond, Guz. Hind.

A term applied to several modifications of a distinct proximate principle of vegetables, of more universal occurrence than any other secretion by plants. Some of these modifications are termed *mucilage*. [When certain seeds or roots are infused in water at 160° or 180°, subjected to pressure in a linen strainer, and the liquor evaporated, the residue resembles gum. Bruised linseed treated in this manner may be made to yield a substance closely resembling Gum Arabic.] In fact, gum is the material usually prepared by plants for their own nutrition; in which state it is in solution; but when the bark is wounded either by the knife, by the puncture of insects, by disease, or by means of certain fungi, the solution escapes to the surface, thickens, and even becomes solid and pulverable. The gums are characterised by forming as viscid, adhesive, or mucilaginous solution with water, and by being insoluble in alcohol; so that the addition of spirits of wine to a moderately strong aqueous solution of gum causes the separation of a white precipitate or magma, in consequence of the alcohol combining with the water, and the gum, having nothing to hold it in suspension, falls down. Another characteristic of gum is its convertibility into mucic or saclactic acid by the action of nitric acid. There are two leading modifications of gum, one of which is represented by *Gum-Arabic*, and the other by *Gum-Tragacanth*; there are many intermediate varieties, amongst which *Cherry-tree Gum* may be distinguished. The different kinds of gums have been classed under the generic terms of *Arabine*, *Tragacanthine*, and *Cerasine*, from *cerasus*, a cherry-tree. Gum-Arabic is the produce of several species of acacia growing in Arabia, India, Upper Egypt, Senegal, &c. It occurs in rounded pieces, or *tears*, and in fragments, up to the size of a walnut, or larger: these are of irregular shape: the colour is either white, yellowish, or dark wine yellow; there is scarcely any odour and the taste is mawkish and glutinous; the sp. gr. varies from 1.30 to 1·50. It breaks readily into small irregular pieces, with an uneven vitreous facture. It dissolves almost completely in water; 100 parts of water at 212° Fahr. take up 19 parts of gum. The solution is, however, purer when made with cold water, and keeps better: it is sometimes used as a glaze or varnish, and for the purpose of giving a gloss and stiffness to ribands, calico, &c. The sp. gr. of the solution being greater than that of water many substances in a state of minute mechanical division which will subside in water, will not do so in mucilage: hence the use of gum in writing ink and in some paints, and in the pigments used in calico-printing, &c. When gum is sold in powder, it is often adulterated with starch the presence of which may be detected by tincture of iodine, which strikes a blue colour: or when cold water is used for the solution, the starch remains undissolved. Gum is highly nutritive, and is used in medicine as a demulcent. At an average of the 3 years ending 1842, the

gum-Arabic entered for consumption in the United Kingdom amounted to 18,176 cwts. a-year. *Gum Senegal*, from the island of that name on the coast of Africa, is largely used by the calico-printers instead of gum-Arabic. Gum-Tragacanth is the produce of certain species of *Astragalus*, growing in Asia Minor, Armenia, and Northern Persia. It is usually in the form of white or yellowish semi-transparent flakes, or curled vermicular pieces, which are very tough, and require, before they can be powdered, to be dried at 212°, when they lose about 10 per cent. of water, and become brittle. When steeped in water this gum swells into a bulky mucilaginous mass, which, when boiled with water, gradually acquires the appearance of a solution of ordinary gum. 100 parts of tragacanth yield 53 of arabine and 33 of tragacanthine, or *bassorine*, a mucilaginous substance forming the bulk of *Gum Bassora*, the remainder being water and oxalate of lime. Gum-tragacanth is used for some of the purposes to which gum-Arabic is applied. It is often sold in the shops as *gum-dragon*. Cherry-tree Gum, including that of peach and apricot-trees, and other species of *Prunus*, resembles inferior gum-Arabic in its external characters, but is only partially soluble in cold water. It differs from it in some of its chemical relations. Gum-Resins are vegetable secretions which are most abundantly and most perfectly produced in warm countries, from trees and shrubs of particular tribes of plants, but rarely from herbaceous plants, except the large herbaceous umbelliferæ, which yield the fœtid gum-resins. They either exude spontaneously, or from incisions made in the stem and branches. "When they first escape to the surface they are fluid, and of a light colour, but gradually harden and become of a deeper hue, either by the evaporation of some of their volatile oil, or by the absorption of oxygen from the air and the conversion of the oil into a resin. Some remain in a semi-liquid, viscid, state, such as *sagapenum* and *galbanum*, which are only pulverizable in winter. Most gum-resins possess a strong odour, (which in many instances is disagreeable, such as that of *asafætida*,) with a warm acrid taste, and by application to the skin for any considerable time, they cause redness and inflammation. Owing to their composition being a mixture of gum and resin, they are not completely soluble either in water or absolute alcohol, but are perfectly dissolved in proof spirit, which is much employed to prepare tinctures of this class of substances. The gum, being soluble in water, is capable for a time of holding the resinous portion suspended in water, thereby forming an emulsion, a state which admits of their administration, if used soon after being prepared; for by rest they separate. Many of them are soluble to a certain extent in acetic acid, especially when assisted by heat. The strong mineral acids char them, and produce chemical changes. "Many gum-resins are popularly termed *balsams*, a designation to which they have no title, as they do not contain benzoic acid." *Artificial Gum.* In the process of calico-printing and for stiffening different goods, an artificially prepared gum has for some years been employed. Starch or fecula is by the action of diastase, a peculiar azotised substance formed during the germination of seeds, converted into a gummy mucilaginous substance named *dextrine*. It is also known in commerce under the name of *British gum* and *torrefied starch*. The term *leiocome* has been applied by Payen to a modified dextrine, whiter and more soluble than can be obtained by torrefication. It is formed by moistening 1,000 parts of dry starch (potato starch is generally used) with very dilute nitric acid, consisting of 2 parts of concentrated acid and 300 of water: the mixture is divided into small blocks, which, when dried in the air, are rubbed down and exposed in a proper drying stove to a current of air heated to about 150° or 160°: the powder is afterwards well dried at a temperature not exceeding 230°. When well made it dissolves in cold or tepid water as easily as gum-Arabic. From a recent paper by M. Emile Thomas, quoted in the *Chemical Gazette*, it appears that artificial gum is manufactured in three distinct forms; viz. as a white, brilliant, pearly powder; as a syrupy solution; and in the form of exotic gum in greater or less perfection, either broken into small fragments, or made into rolls of various sizes. Dextrine is manufactured either by the use of acids or by means of the diastase contained in malted barley. When sulphuric acid is used, the dextrine is deliquescent, and the products often coloured: hence this acid is not used. Pure nitric acid is commonly employed for obtaining dextrine in the state of powder, as in M. Payen's process. Muriatic acid is also used for rendering the starch soluble, and it is then dried at a high temperature. The powder thus obtained is thrown upon a metallic sieve, and submitted to the action of a jet of steam, which moistens the dextrine so as to render it transparent without liquifying it: after this it requires very little drying. This process, however, requires more skill than can be expected of an ordinary workman. The process by diastase seems to be the most advantageous. The fecula is rendered soluble in vats heated by steam in such a manner that the temperature may be easily raised or lowered. The fecula is first mixed with 4 times its weight of water at about 122° Fahr. At one operation 600 lbs. of fecula are mixed with 1,200 quarts of water. The temperature must be kept at about 140° until the whole mass is converted into starch; 2 per cent. by weight of very white malted barley is then added, and also the mucilage produced from 1 per cent. of linseed. If a larger proportion of malt were used, the decomposition would be more rapid, but a larger quan-

tity of glucose would be formed, and the gum would be more coloured. The mucilage of linseed imparts tenacity to the gum. The mixture must be kept at about 120° or 140° until all the starch is again dissolved; the temperature should then be suddenly raised, taking care, however, not to exceed 167°, but keeping as near that temperature as can be in order to cause the diastase to act as powerfully as possible. The mixture is then to be well stirred until the decomposition is almost complete: this may be ascertained by testing with iodine, which ought to give a violet approaching to red, instead of the characteristic blue tint. During the decomposition the liquid must be kept constantly in motion: the operation lasts about an hour and a quarter; that is to say, a quarter of an hour for the formation of the paste, one for its dissolution, and the other three-quarters for rendering it soluble. The liquor is then removed from the decomposing vats, and left in pans to settle for from 6 to 18 hours, according to the external temperature. During this time a slight fermentation will be perceptible, but it must be checked by adding alum in the proportion of 10 grammes for every 25 gallons of liquid. By allowing this time for the mixture to settle, the colouring of the gum while being baked is avoided. When drawn off, the liquor will mark about 10° B: it is then evaporated by raising it very slowly to the boiling point, the perfect clarification being accelerated by checking the first boiling, as in refining sugar. This clarification is effected without any foreign agent, by the coagulation of the vegetable albumen contained in the malt and the linseed mucilage. The scum which rises to the top must be carefully removed. If the boiling be hastened, the gum will first become thick, and afterwards be coloured. When a solid pellicle of gum forms on the surface, the baking will be completed, at which time the syrup will mark about 35° B. If the gum is to be kept in a liquid form, the baking must be stopped at 30° while boiling, and the syrup be poured into well-closed vessels, previously rubbed with oil of turpentine, and the surface of the gum be covered with a thin layer of that oil. This method is tolerably successful in preventing fermentation. When it is desired to solidify the gum, the boiling syrup is poured into small flat tin vessels, placed upon a hot-air stove, kept at a temperature of from 104° to 122°. At the end of 24 hours the gum will acquire the consistency of jujube paste: it is then to be cut up with a pair of shears into small oblong pieces, and these are to be rolled out upon a polished table with a wooden roller, dusted with pulverized artificial gum, and afterwards placed upon wooden frames, and left for 3 or 4 days to dry. The artificial gum, thus prepared dissolves easily, and makes a very clear solution. —*Tomlinson.*

(4194) GUNNY.

Goonpat, Gooni, Pat, Guz Hind.	Gooni, Beng. Gooni, Tel.

A strong, coarse sack-cloth manufactured in Bengal, for making into bags, sacks, and packing generally. The material from which this article is manufactured is the fibre of two plants of the genus *Corchorus;* viz, *Corchorus olitorius*, and *Corchorus capsularis*, (*Beng.* Pat), both, but particularly the first, are extensively cultivated throughout lower Bengal. Besides a large domestic consumption of gunny, the whole rice, paddy, wheat, sugar, saltpetre, &c, of the country, as well as the pepper, coffee, and other foreign produce exported from Calcutta, are packed in bags or sacks made of this article; and which is put to similar uses all over India, and other places to which it is exported.—*McCulloch. Faulkner.* It is woven of various lengths and generally about 8 inches wide. Buchanan describes the process of growing the hemp and preparing the article in the neighbourhood of Bangalore.—*Rohde. M. S. S.* The sugar of India is brought to England in them, and they are very largely exported to America for packing their cotton. In the year 1850-51, the Gunnies and Gunny cloth exported from Calcutta were in number 9,035,713, valued at Rs. 2,159,782, two thirds of this amount being sent to North America, the Coromandel and Malabar coasts, Pinang and Singapore, besides this 58,950 gunny bags were exported from Madras and Bombay, re-exports to the value of half a lac of Rupees. The kind of cloth of which the Gunny bags are made, is called in Bengal, "*Chatu,*" in Tamil "*Koni,*" Tel. Goni also "Tat." It is of three different kinds, and is always woven in pieces from three quarters to one cubit wide, of which two or three are sown together, at the sides, into one piece, before offering it for sale. The first kind, intended for bedding is four to five cubits long, and from two and a quarter to three cubits wide, and sells at about 8 rupees per 100 pieces. Secondly that intended for covering bales of cloth is of the same dimensions, but is thicker than the former kind, and costs from 6 to 10 rupees per 100 pieces. Thirdly that intended for making rice and sugar bags, is five cubits long and one and a half, or one and a quarter cubit wide, and ten bags cost four or five rupees. On all the Eastern frontier, a great proportion of the women are clothed with coarse cloth, made from the jute.—See Corchorus.

(4195) GUNDUNA. Allium Porrum. Leek.

(4196) GUNPOWDER.

Krudt, Pulver, Dan.	Pulvis pyrius, Lat,
Buskruid, Dut,	Proch, Pol.
Poudre Fr.	Polvora, Port.
Pulver, Schiesspulver, Ger.	Poroch, Rus.
Baroot, Daroo, Guz. and	Polvora, Sp.
Polvere, It [Hind.	Krut, Sw.

A well known inflammable powder, which is composed of certain proportions of nitre, sulphur

and charcoal, reduced to a powder, and mixed intimately together.—*Faulkner.*

(4197) GUNTA BARINGA.

Sheerudek, TAM. | Ghentoo baruughie, TEL.
Cund baruughie, DUK. | Baruughie, SANS.

Gunta baringa is the root of a plant growing in the hills about Lamsingi to the W. of Vizagapatam. It is mentioned by Ainslie p. 112. (1st Ed. 4to,) under its Tamil name "chirudekku." (Honorable Mr. Elliot). The same drug is contained in the Canara and Travancore collections: the plant yielding these roots is unknown.—*M. E. J. R.* This root continues to be used in Southern India by native practitioners as a febrifuge. Ainslie says, "it is a small, knobby, somewhat warm and slightly bitterish tasted root which the natives prescribe in fever and catarrhs. From the word Paringhee, it is perhaps brought from some foreign country." From its low price Dr. Cleghorn is inclined to think this improbable and he is not without hopes of soon ascertaining to what plant it belongs. Of its absolute antiperiodic qualities nothing seems to be known with accuracy.—*Ind. Anns. Med. Sci. for April* 1856, *page* 397. An infusion or decoction of the leaves and tender shoots of this plant, the Vyteans consider as attenuant and diaphoretic: they are said to be slightly bitter and not unpleasant to the taste.—*Ainslie's Mat. Med. page* 112.

(4198) GURANYO ALOO. DIOSCOREA RUBELLA.—Red Sweet Yam. This is an oblong and red skinned root, tuberous, deeply tinged with red under the skin, but the colour does not penetrate deep; they are sometimes as much as three feet long in a rich light soil.—*Riddell.*

(4199) GURANYO ALOO LAL. DIOSCOREA PURPUREA.—Purple Yam. Root oblong; throughout of a lighter or dark purple, but always considerably deep in tinge. This colour is permanent.—*Riddell.* Zemmy kund. Dioscorea atro purpurea.—Another species. Tubers subrotund purple throughout, very large, of an irregular, smooth, roundish shape, and growing near the surface, so as to appear in dry weather through the cracks they make by raising the soil over them.—*Riddell.*

(4200) GUR-BATAS. Root of a climber brought to Ajmere from Delhi: has a bad smell: is considered astringent and cooling; much used in horse mesalihs: four seers for one rupee.—*Gen. Med. Top. p.* 135.

(4201) GURJUN OIL. GURJUN KA TEL.—Oleo-resinous liquid afforded by several species of Dipterocarpus: deep brown, transparent, of nauseous odour; sometimes thick and white.—See DIPTEROCARPUS.

(4202) GUTTA PERCHA. According to Dr. Montgomerie, this word is a pure Malayan one, *gutta* meaning the gum or concrete juice of a plant, and *percha* the particular tree from which this is procured. The *ch* is not pronounced hard, like a *k*, but like the *ch* in the English word *perch*. It is the concrete juice of a forest tree, a native of the shores of the Straits of Malacca, Borneo, and the neighbouring countries. The natives had themselves discovered its valuable properties before they became known to Europeans. They constructed whips, buckets, and vessels of various kinds out of the hardened juice, and thus excited the attention of travellers to a snbstance which has since been applied to a vast variety of domestic and scientific purposes in Great Britain. Their method of proceeding, however, has been of the most destructive kind, especially since the demand of a European market for this substance has had to be met. Instead of economising their treasure, as is done in the case of the caoutchouc, by tapping the tree and allowing its juice to ooze gradually from the incision, they fell the trees at once, and removing strips of bark at intervals, collect indeed a large quantity of sap at one time, but destroy all future supplies from that source. This wholesale destruction of the gutta trees, which are naturally slow of growth, must, if unchecked, necessarily involve the destruction of the traffic, which is now so brisk and advantageous in this article. To put any check upon these proceedings is said, moreover, to be extremely difficult; because each set of explorers, in searching after these trees, is more anxious for present profit, than for future benefit, to the trade. A very small quantity, comparatively speaking, is to be obtained by tapping, and it is evidently to the interest of the first comers to get a full supply of sap for themselves, without considering those who came after, and who might very probably cut down the trees if they had been spared previously. The first accounts which reached us of these trees were given by the late Dr. Montgomerie, of Bengal, who appears to have been the first person to notice the native use of this substance: this was in 1842. In 1843, Dr. D'Almeida presented a specimen of their inspissated juice to the Royal Society of Arts, and described some of the advantages which would accrue from its use. This communication led to no results; but another, made shortly after by Dr. Montgomerie, was more successful, so that by the united efforts of these gentlemen Gutta Percha was introduced to public notice, and soon told its own tale to manufacturers. They could not be blind to the advantages offered by a material possessing many of the properties of caoutchouc, with others in addition essentially its own. The abundance of the supply also encouraged invention, and in a very short time Gutta Percha was applied to multifarious uses, and became a valuable auxiliary in the arts. The tree which produces this substance is from sixty to seventy feet high, and three or four feet in diameter. Its foliage is of a pale green on the upper side, and

covered with reddish-brown hairs beneath. Specimens of the flowers and fruit are exceedingly difficult to be obtained. The tree flourishes luxuriantly in alluvial tracts, at the foot of hills, and forms in many places the principal part of the jungle in such situations. From a communication of Sir W. J. Hooker to the London Journal of Botany, it appears that numerous well-dried specimens of the Gutta Percha, though unfortunately without corollas, were sent to England, by Mr. Lobb, during his botanical mission in the East, accompanied by sections of the wood, which is peculiarly soft, fibrous and spongy, pale-coloured, and traversed by longitudinal receptacles or reservoirs, filled with the gum, forming ebony black lines. Application was then made to Dr. Oxley, of Singapore, for flowering specimens, and these were immediately supplied by him in the most obliging manner, and transmitted to England in a thin box, the top and bottom of which were made of sheets of the gum itself (now deposited in the Museum of the Royal Gardens at Kew.) From the more accurate knowledge obtained by means of these specimens, Sir W. J. Hooker was able to refer the plant to Dr. Wight's new genus of Sapotaceæ, called Isonandra, and to name the plant *Isonandra gutta*. After the natives have cut down the full-grown trees, they make rings in the bark at the distance of every ten or twelve inches, placing under each, as they make it, a cocoa-nut shell, or the spathe of a palm, as a receptacle for the milky sap which begins to flow immediately that the incision is made. The sap is collected in bamboos, taken to their houses, and boiled in order to drive off the watery particles, and inspissate it to the proper consistence. Boiling appears necessary when the juice is collected in large quantity, but when a small quantity is allowed to exude from a freshly-wounded tree, and is collected and moulded by the hand, it consolidates perfectly in a few minutes, and has all the appearance of the prepared articles. Gutta Percha when quite pure is greyish white, but it is generally brought to market of a reddish-brown hue. This is ascribed to chips of the bark, which fall into the sap and give it their colour, but in addition to this there are frequently other matters, such as saw-dust, purposely introduced as adulterants. Dr. Oxley, of Singapore, in an interesting description of this substance, first printed in a Singapore periodical, in the year 1847, states that the tree which yields Gutta percha was formerly very abundant on that island, but already all the large timber has been felled, and few and but very small plants are to be found. "The range of its growth," he says, "appears to be considerable, it being found all up the Malayan peninsula, as far as Penang, where I have ascertained it to be abundant, although as yet the inhabitants do not seem to be aware of the fact, several of the mercantile houses there having sent down orders to Singapore for supplies of the article, when they have the means of supply close at hand. The tree is also found in Borneo, and I have little doubt is to be found in most of the islands adjacent." Respecting the wholesale destruction of the trees, the same writer observes,—"The quantity of gutta obtained from each tree varies from five to twenty catties, so that, taking the average at ten catties, which is a tolerable liberal one, it will require the destruction of ten trees to produce one picul. Now the quantity exported from Singapore to Great Britain and the Continent, from 1st January 1847 to July, 1847, amounts to 6,918 piculs, to obtain which 69,180 trees must have been sacrificed. How much better would it, therefore, be to adopt the method of tapping the tree, practised by the Burmese in obtaining the caoutchouc from the *Ficus elastica*, (viz., to make incisions in the bark, placing bamboos to receive the sap, which runs out freely) than to kill the goose in the manner they are at present doing. True, they would not at first get so much from a single tree, but the ultimate gain would be incalculable, particularly as the tree seems to be one of slow growth, by no means so rapid as the *Ficus elastica*. I should not be surprised if the demand increases, and the present method of extermination be persisted in, to find a sudden cessation of the supply." The great peculiarity which makes Gutta Percha convenient and valuable for a variety of purposes is, that when plunged into boiling water, it becomes so soft and plastic as to be easily moulded into any desired form, and this form it permanently retains on cooling. It was the discovery of this fact which first led the Malays to fabricate it into whips, and subsequently into basins, jugs, shoes, traces, &c. The Medical profession soon became aware of its extreme value and applicability in the practice of surgery. Dr. Oxley early discovered it to be "the best and easiest application ever yet discovered in the management of fractures, combining ease and comfort to the patient, and very much lessening the trouble of the Surgeon." He also employed it for bougies, capsules, tubes for syringes, &c." Gutta Percha tubing has been found extremely useful for water service, and for the conveyance of sound. Its extraordinary strength fits it for the former use in a remarkable degree. A series of interesting experiments were made two or three years ago at the Birmingham waterworks, to ascertain the strength of tubes of $\frac{3}{4}$ inch diameter, and $\frac{1}{8}$ inch thickness. These were attached to the iron main, and subjected for two months to a pressure of two hundred feet head of water without being in any way deteriorated. In order to ascertain the maximum strength of the tubes, they were connected with the Company's hydraulic proofing pump, the regular load of which is 250 lbs. on the square inch. At this point they were unaffect-

ed, and the pump was worked up to 337 lbs., but to the astonishment of every one the tubes still remained perfect. It was then proposed to work the pump up to 500, but it was found that the lever of the valve would bear no more weight. The utmost power of the hydraulic pump, therefore, was ineffectual to burst these tubes. In the conduction of sound gutta percha is also found remarkably useful. Speaking tubes of this substance for the conveyance of messages are now fitted up in mines, railway stations, prisons, workhouses, hotels, and other large establishments. Partially deaf persons are found to appreciate its value: an ingenious apparatus for their use has been devised, including the distribution of the gutta percha tubing over a church or other large building, so that, by seating themselves at particular parts where these tubes terminate, such persons are able to hear distinctly the sermons or speeches delivered therein. Gutta percha is also brought to the aid of the architect in the ornamental work of the interior of houses. It appears to be admirably adapted for cornices and centres for ceilings, also for picture-frames, and many other uses to which plaster and papier machie have hitherto been applied. It has likewise been employed for door handles and plates, for knife handles, vases, baskets, &c., for the stopping of decayed teeth and for printing in relief. The clear, sharp impression it receives, and the toughness of the substance, have made it very useful in books for the blind, and in maps embossed for their benefit. In solution this substance is employed in waterproof clothing; mixed with caoutchouc and other substance it is made into a light, porous, spongy material, suited for stuffing or forming the seats of chairs, cushions, and mattresses. Springs of clocks, clasps, belts, garters and string, are prepared from the modification of the above mixture, while moulds and balls of gutta percha are produced of a hardness sufficient to bear turning in the lathe, like wood or ivory. A varnish may also be made in which gutta percha, being the principal ingredient, may be used to give a waterproof covering to other substances. Gutta percha dissolves at ordinary temperatures, and still better at a higher heat in sulphuret of carbon. The solution leaves behind on a glass plate a thin coating, possessing all the properties of gutta percha, unaltered. Paste-board boxes coated over with this may be made to hold water. Electrical experiments are aided by the use of gutta percha, for it has been found by Dr. Faraday to possess high insulating power. A letter from this distinguished philosopher, published in the "Philosophical Magazine," in March 1848, gives the following among other particulars;—"A good piece of gutta percha will insulate as well as an equal piece of shell-lac whether it be in the form of a sheet, a rod, or filament; but being tough and flexible when cold, as well as soft when hot, it will serve better than shell-lac, in many cases where the brittleness of the latter is an inconvenience. Thus it makes very good handles for carriers of electricity in experiments on induction, not being liable to fracture; in the form of thin band or string, it makes an excellent insulating suspender; a piece of it in sheet makes a most convenient insulating basis for anything placed on it. It forms excellent insulating plugs for the stems of gold-leaf electrometers, when they pass through sheltering tubes, and larger plugs supply good insulating feet for extemporary electrical arrangements: cylinders of it, half an inch or more in diameter, have great stiffness, and form excellent insulating pillars. Because of its good insulation, it is also an excellent substance for the excitement of negative electricity. It is hardly possible to take one of the soles sold by the shoemakers out of paper, or into the hand, without exciting it to such a degree as to open the leaves of an electrometer one or more inches; or if it be unelectrified, the slightest passage over the hand or face, the clothes, or almost any other substance, gives it an electric state. Some of the gutta percha is sold in very thin sheets, resembling, in appearance, oiled silk; and if a strip of this be drawn through the fingers, it is so electric as to adhere to the hand or attract pieces of paper. The appearance is such as to suggest the making of a thicker sheet of the substance into a plate-electrical machine for the production of negative electricity. Then as to inductive action through the substance, a sheet of it is soon converted into an excellent electrophorus; or it may be coated, and used in place of a Leyden jar, or in any of the many other forms of apparatus dependent on inductive action." The properties thus noticed could hardly fail to bring this substance into use in telegraphic communication. Being flexible, impervious to water, and possessing insulating power, it is the most efficient of all substances as a coating or tubing for the copper wire of submarine telegraphs. Thus it aids in producing the most marvellous annihilation of time and space our age has yet witnessed. Gutta percha has been analysed by Dr. Maclagan, who obtained as its per centage composition, carbon 86·36; hydrogen 12·15; the remainder 1·49, was most probably oxygen absorbed from the air during the process of purifying it, as the substance whilst heating on the vapour bath acquired a brown colour. Respecting the purification of gutta percha, Dr. Oxley gives a good hint to manufacturers when he says that gutta ought not to require an elaborate process: the simple boiling in water, and rolling out into sheets, whence all foreign matter can be easily picked off, is the only process he employs, and this he thinks would be generally sufficient, if manufacturers in giving their orders would take the precaution of requiring that the article should be strained through a cloth at the

time of its collection, and if they would encourage the natives to do this, by offering a somewhat higher price for gutta percha so prepared. A vast deal of trouble and expense might, in his opinion, be saved in this way, and the various processes rendered unnecessary, which have from time to time been suggested for the purification of gutta percha. The preparation of this substance for use is carried on on a large scale in the following manner ;—the lumps of gutta as they are received at the factory are first brought within the action of a vertical wheel, on the face of which are fixed three knives, which, as the wheel moves at the rate of two hundred revolutions, per minute, rapidly cut the lumps into thin slices, discovering whatever adulterating materials may be contained therein. The gutta thus torn up is not uniform in colour or texture, but it is rendered so by the subsequent operations. It is first softened by soaking in hot water (by which also the dirt and other impurities become separated from it) and then thrown into a rotating machine, where it is dragged asunder by jagged teeth and reduced to fragments. These fragments fall into water, which still further tends to purify them, and are then softened into a paste in hot water, kneaded, and rolled between heated cylinders, so that all parts may become thoroughly mixed and uniform. It may be then rolled out into sheets between steel rollers, or passed in the mass through heated iron cylinders, and made into tubes, or converted to the thousand purposes of ornament or use which we have briefly indicated. In the Great Exhibition, gutta percha was seen in a vast variety of forms, but none were more interesting than those which illustrated the successive stages of its manufacture. The original lump, the slices, the shreds, the kneaded mass, the sheets ready for use ; all appeared there. A very ingenious adaptation of the substance to making stereotype plates attracted much notice. A mould is taken by pressure of a page of type with woodcuts, in gutta percha ; from this mould a cast is obtained on a cylinder of gutta percha, and from this last the printing is carried on. An hour, it is said, suffices to make both mould and cylinder. See ISONANDRA; also PAUCHONTEE.—*Tomlinson.*

(4203) GUTTIFERÆ, Jussieu. (CLUSIACEÆ, Lindl.) Trees, rarely shrubs, sometimes parasitic climbers, abounding in yellow, resinous juice, branches opposite, often four sided. Leaves decussately opposite, coriaceous, shining, without stipules. Flowers perfect or polygamous, usually terminal, sometimes axillary, articulated with their peduncles. Calyx 2, 4 or 6 leafed, persistent. Petals equal in number to leaflets of the calyx, alternating with them or opposite, occasionally numerous. Stamens usually numerous, free, united into a ring, or tube, or into separate bundles. Disk fleshy, angled or lobed. Ovary one to 5 or many-celled. Ovules solitary or twin, erect or ascending, in a single-celled ovary, abou 4 or many attached to central placentæ. Stigm peltate or radiate. Fruit capsular, drupaceous or baccate. Embryo without albumen, straight The Guttiferæ are allied to Ternstrœmiaceæ an to Hypericineæ, and are found in the tropica parts of Asia and of America. Many of the spe cies yield a yellow, resinous juice like Gamboge useful both as a pigment and as a medicine. Th fruit of some is edible, the seed oily, and th wood hard and useful as timber.—*Royle.* Th *Guttifers*, are a small natural order of Exogenou Plants, inhabiting the hotter parts of tropica countries in both the Old and New World. Thei fruit is succulent, juicy, and in many cases re sembling a large apple or orange. The Mango steen (*Garcinia Mangostana*) is probably the mos delicious of any known ; but it has never beer seen in a fresh state in Europe, for the tree wil hardly exist out of its native, humid, heated atmosphere in the Indian Archipelago. The mos remarkable product of this order is an acrid purgative, yellow gum-resin. In one of its form this is the Camboge or Gamboge of commerce. This substance is well known as a yellow pigment, as also a purgative medicine. The plan which yields the Gamboge of commerce is stil unknown. The London College of Physicians in their 'Pharmacopœia' refer it to some species of *Garcinia*, others refer it to species of *Cambogia*, *Xanthochymus*, *Hebradendron*, and *Stalagmitis*. The East India Tacamahaca is yielded by a species of *Calophyllum*. The Butter o Tallow-Tree of Sierra Leone is the *Pentadesma butyracea*. The fruits of many species are esteemed, besides the Mangosteen. The Mammee Apple, or Wild Apricot of South America, is said to be very delicious. Its seeds are anthelmintic ; its flowers yield on distillation a spirit known as Eau de Creole, and wine is obtained by fermenting its sap. The large berries of the Pacourynva (*Platonia insignis*) of Brazil are highly prized on account of their delicious flavour. The fruits of several species of Garcinia besides the Mangosteen, are brought to table in the countries where they grow, but they are regarded as very inferior. The blossoms of *Mesua ferrea* are remarkable for their fragrance, and are sold in the bazars of India under the name of Nagkesur.—*Engl. Cyc. Vol.* II. *p.* 5.

(4204) GYMNEMA, a genus of Plants belonging to the natural order *Asclepiadaceæ*. It has a sub-urceolate 5-cleft corolla, the throat usually crowned by five scales or teeth inserted in the recesses between the segments of the corolla. The stamineous corona is wanting. The anthers terminate by a membrane, the pollen masses are erect, fixed by the base. The follicles smooth. Seeds comose, generally marginate. The species are usually twining shrubs, natives of the East Indies, the tropical parts of Australia, and Equinoctial Africa. The leaves are opposite,

membranous, and flat. The umbels interpetiolar and cymose. In the greater number of species the stamens are not usually naked, but are furnished with a gland-like body or fleshy tuft at the base of each filament.—*Eng. Cyc.* A dye of an excellent quality has been obtained from a twining plant, Gymnema (Asclepias) tingens. It is a native of Pegu but grown in Burmah, where a green dye is extracted from its leaves.—*Simmonds.* Dr. Wight in Icones gives Gymnema Decaisneanum, 1271; elegans, 830; hirsutum, 1271-72; lactiferum, 343; sylvestre, 1271-349; tingens, var. cordifolia, 593; tingens, var. ovalifolia, 592.

(4205) GYMNEMA LACTIFERUM, Cow-Plant, or Milk-Bearing Gymnema, has an erect stem, or rather twining; the leaves are on short petioles, ovate, bluntly acuminated, usually unequal-sided; the umbels many-flowered, shorter than the petioles; the throat of the corolla crowned by five fleshy tubercles; the tube furnished with double pilose lines running from the tubercles. It is a native of Ceylon, where the milk of the plant is sometimes substituted for cow's milk, and the leaves are boiled with food.

(4206) GYMNEMA TINGENS, is a native of Pegu. It has a twining glabrous stem, cordate leaves, acuminated to oval; the umbels or corymbs often twin, at first shorter than the petioles, and at length spirally elongated; the glands of the filaments one-half shorter than the stamens; follicles cylindrical, spoon-shaped; stigma simple, oval, mutic, crowning the tube of the corolla, and therefore exceeding the stamens. The flowers are largish, numerous, and of a pale-yellow colour. The calyx 5-cleft to the base. From the leaves of this plant a green dye is prepared by the Burmese. Seventeen species of this genus are enumerated, none of them of any particular interest. (Lindley, *Vegetable Kingdom*; Don. *Dichlamydeous Plants.*)

(4207) GYPSOPHILA Silenaceæ. Gypsophila Elegans. This is a genus of small creeping plants, flowers of various colours, and will grow in any common soil.—*Riddell.*

(4208) GYROCARPUS, a genus of Plants containing few species, but these few are widely distributed—one being found in South America on the mountains of New Granada and Caraccas, a second on those of the Coromandel coast, and two others in the tropical parts of Australia. *Gyrocarpus* has, in conformity to the opinion of Mr. Brown, been considered as allied to, and by some it has been placed in, *Lauraceæ.* Blume refers it to his new order of *Illigereæ.* Dr. Lindley considers it has belonging to *Combretaceæ.* The flowers are polygamous or hermaphrodite; the perianth superior, 4- to 8-fid; stamens 4, opposite to divisions of perianth; anthers 2-celled, with the cells opening by a valve from below upwards; drupe 1-seeded, having attached to it two long membranous wings, the prolongation of two divisions of the perianth as in *Dipterocarpeæ.* The embryo is inverse; the cotyledons twisted spirally. The American is so closely allied to the Asiatic species as to have been thought identical by Dr. Roxburgh. The latter grows to be a large tree with cordate leaves which are deciduous about the end of the rainy season; after which the flowers make their appearance in the cold weather, but are shortly followed by the new leaves. The wood of this tree is whitish-coloured and very light. It is preferred whenever procurable for making the catamarans, or rafts, on which the natives come off to ships through the heavy surf of the Madras coast.

(4209) GYROCARPUS JACQUINI.

Tanuka, Tel.

Grows to be a very large tree, is chiefly a native of the mountainous parts of the coast of Coromandel. Leaves deciduous about the end of the wet season. Flowers during the cold season when the trees are naked, the leaves come out soon afterwards. The wood of this tree which is white and very light, is employed to make catamarans (floats), when to be had, in preference to any other.—*Rox. Rohde, M.S.S.*

(4210) GYPSUM is one of the varieties of native sulphate of lime, and is so named from γῆ, earth, and ἕψειν, to concoct; *i. e.* formed or concocted in the earth. The structure is fibrous and earthy. It is widely distributed throughout the world, and was well known to the ancients, who applied it to many of the same uses for which it is valued at the present day. In England it abounds in the London and other clays, but its great repository is in the rock commonly called new red sandstone. Numerous quarries exist in that formation, and those of Derbyshire, South Yorkshire and Nottinghamshire are in high repute. The better sorts of Derbyshire gypsum are employed in the Staffordshire potteries, as an ingredient in certain kinds of earthenware and porcelain, and also in making moulds for such articles of pottery as cannot be shaped on the common wheel. The finest pieces of this gypsum are reserved for ornamental purposes, such as vases, small statues, &c., of which a considerable manufacture exists in Derby. Gypsum in this form generally bears the name of *alabaster*, [There is some doubt as to the derivation of this word, but it is supposed to be from α, without, and λαβον, a handle, referring to a vase or box without handles, for containing perfumes.] and is remarkable for its softness, purity of colour, and fragile character: once soiled, its purity cannot be restored by ordinary washing, and it is also extremely liable to crack. Articles of delicate workmanship in this material are therefore preserved under glass. Alabaster abounds in the tertiary strata of Montmartre, near

Paris, and sometimes it forms entire hills. In the Tyrolese, Swiss, and Italian Alps it is found upon the primitive rocks, often of the purest white, especially at Montiers, near Mont Blanc, and near the summit of Mont Cenis. Gypsum, when calcined and reduced to powder, can be brought to a pulpy mass by admixture with water, and is the well known *Plaster of Paris*. This mass very soon sets, or returns to the solid form, giving out, while in the act of doing so, a considerable degree of heat. Advantage is taken of this fact in the use of gypsum as a material for casting and taking impressions. The writings of Theophrastus and other Greek authors show that this use of gypsum was known to them. They distinguished two kinds of gypsum, the pulverulent and the compact; the latter was obtained in lumps, which were burnt in furnaces, and then reduced to powder. This powder, mixed with water, formed a cement for buildings, and was also used for taking impressions. Casts were taken in gypsum from the living face: from the moulds thus formed other casts were taken in wax, that soft material allowing any imperfections which had occurred in the plaster casts to be rectified. Gypsum was also employed in stucco work for wreaths, medallions, and other ornaments of ceilings, cornices, &c. The purest gypsum is required in making casts: the best part of the crystalline gypsum rocks of Newark is well adapted for that purpose. This should be quarried in dry weather, stacked under covered sheds, and conveyed to the place of manufacture in a perfectly dry state. Here it is sorted into two or three qualities, the central part of each block, which is the finest and best, being selected. The calcining ovens are heated with billet-wood, and the gypsum, previously reduced to small pieces, is thickly strewn on the floor of the oven to the depth of five or six inches. The door is then closed, and kept in that state for twelve hours, after which it is opened, but the gypsum is left for two or three hours longer. It is then placed in covered boxes, and finally ground between stones, and run through a lawn sieve. This process gives a gypsum fit for medal-casting, and other fine purposes. Gypsum in this powdered state may be preserved uninjured for any length of time, if perfectly excluded from the air, but as this is nearly impossible, it is better not to prepare a large quantity at one time. The quality of the powder may be tested by an experienced person, simply by squeezing it in the hand: if it cohere slightly, like wheat-flour, it is good; but if it fall to pieces immediately, it has been injured by damp. In the baking of the gypsum care must be taken not to overheat it, or it will assume the crystalline character of *anhydrite*, and not set on the addition of water. The specific gravity of anhydrous sulphate of lime (artificial) is 2·927. Alabaster is not so often used by the lapidary as by the sculptor, but its treatment, when employed by the former, varies somewhat from the general practice with harder stones; therefore we give a short abstract of the description furnished to M. Holtzapffel by the best lapidaries:—

In working alabaster to the required forms, the lapidary first employs the slitting-mill, which is a thin plate of iron fixed on a vertical spindle, and made to revolve with moderate velocity, the edge being charged with diamond powder, and lubricated with the oil of brick. The alabaster is then roughly ground at a *roughing* or lead-mill, which is a flat circular plate of lead, fixed on a spindle, and travelling on a horizontal plane: this is abundantly supplied with coarse emery and water by means of a brush. The alabaster is moved to and from the centre of the rapidly-revolving lap, until all the marks of the slitting-mill are removed, and the stone is reduced to a flat surface. The alabaster is then smoothed at the same mill with flour emery, after which it is removed to the *wood-mill* to be smoothed. This is a disk of mahogany used with flour-emery and water: it is more effective than the roughing-mill, because more elastic, and because the slight roughness of its face from the rubbing up of the fibres of the wood act more quickly and satisfactorily than metal. The alabaster is now ready for polishing, which is accomplished at a *list-mill* with pumice-stone and water; but as the list, which is wound on spirally, is very elastic, flat works must be lightly applied, or they will sink into the soft face of the list-mill, and become rounded at the edges. The polishing is completed at a leather lap, or thick piece of buff-leather, pasted on a wooden disk, and supplied with fine putty-powder and water. Sometimes the naked hand, and a little moistened putty-powder, are finally used for the last polish. Amber, coral, jet, malachite, steatite, turquoise, and some other substances, are treated in nearly, or exactly the same manner as alabaster. The cleaning of alabaster is effected as follows. The soiled object is immersed in cold spring-water for four or five days; the water is then changed, and a small quantity of lime is added, in which solution the alabaster is allowed to remain four or five days longer. It is then thoroughly rinsed, and exposed to dry in the open air. If the process fails on the first trial, it is repeated, and sometimes a third application becomes necessary. Earthenware-pans should be used, as wooden tubs stain the alabaster. Objects that consist of several pieces will be severed by this process, but can easily be re-united with plaster-of-Paris. The pores of the alabaster will also be opened, and it will exhibit its natural granular and sparkling appearance; but the more opaque effect can be restored by using putty-powder, applied with a rag or stick. Oriental alabaster is a compact substance differing materially from the above; it is a stalagmitic

carbonate of lime, of the same hardness as marble, and used for similar purposes. It is found of all shades, from white to brown, and sometimes veined with coloured zones. The magnificent Belzoni sarcophagus, purchased by Sir John Soane for 1,000 guineas, and exhibited at his museum, is of stalagmite. There are also fine specimens in the Egyptian Gallery of the British Museum.—*Tomlinson.* Extensive beds of crystalline and fibrous Gypsum and Selenite occur near Ennore, the Red Hills, Ootatoor, Tiagur, Madura, Bangalore, Masulipatam, Hyderabad, and other localities. These are not put to any use except in the vicinity of Madras. The substance can be purchased in most bazars in India under the name of *kulnar* and *kurpoora silasit*, and is used in small doses as a medicine, but the Natives do not appear to be acquainted with the uses of this mineral in taking casts, plastering and house decoration, or in manufacturing Keene's cement. The best qualities are from Ootatoor near Trichinopoly, the Chingleput District, Sadras, Ennore, the Red Hills, Nellore, Masulipatam and Bangalore. The only new localities for this mineral are Sadras, the Red Hills, and Nellore. It is now known to occur very abundantly in the Madras Presidency in two forms, the Fibrous and Crystalline Gypsums, both free from Carbonate of Lime, and well suited for the Manufacture of Plaster of Paris, for moulds, busts, statues or ornaments. The Fibrous Gypsum of Bangalore, Tiagur and Nellore are the thickest and best, it is not yet known in what strata they occur, as the accompanying Fossils have not yet been traced and the natives seem averse to show the localities for this mineral, though rewards of 20 Rupees have been offered for this information.—*M. E. of* 1857.—*Crystallized Foliated sulphate of lime.*—A fine transparent crystal of selenite in the shape of a parallelopiped was brought to Mr. Mason by a Burman, who said it was found in Amherst Province. —*Mason.* Granular Gypsum, is found near the banks of the Tenasserim in about latitude 13° 40' N. It is granular and friable, and does not correspond in appearance to ordinary specimens; but Dr. Morton, who analyzed it, pronounced it a decided sulphate of lime. A fine variety of fibrous gypsum, *Sulphate of lime, Shakoung*, (*Chinese*,) is seen in some of the China shops; but it is brought, the Chinese say, from China. They use it in medicine, and say "it is very cooling"!—*Mason.* Gypsum, is brought to Canton in abundance, from the North West of the Province, and is ground into powder, in mills. It is not used as manure by the Chinese, but mixed with oil to form a cement for paying boats after they have been caulked. The powder is employed as a dentifrice, a cosmetic, and a medicine, and sometimes, also, is boiled to make a gruel in fevers, under the idea that it is cooling. The bakers who supplied the English troops at Amoy, in 1843, occasionally put it into the bread to make it heavier, but not, as was erroneously charged upon them, with any design of poisoning their customers, for they do not think it noxious; its employment in colouring tea, and adulterating the ping fa, or powder sugar, is also attributable to other motives than a wish to injure the consumers.—*Williams' Middle Kingdom, page* 242.

H.

(4211) HABENARIA, a genus of Plants belonging to the natural order *Orchidaceæ*. This genus has a ringent hooded perianth, a 3-lobed entire spurred lip. There are three species natives of Great Britain, and Wight, in Icones, gives the following species of Southern Asia: affinis, 1707; cephalotes, 1711; crinifera, 926; decipiens, 1714; digitata, 1701; eliptica, 1706; fimbriata, 1712; foliosa, 1700; Heyneana, 923, 1703-4; Jerdoniana, 1715; Lindleyana, 922; longicalcarata, 925; montana, 927, 1714; ovalifolia, 1708; peristyloides, 1702; plantaginea, 1710; platyphylla, 1709; rariflora, 924; Richardiana, 1718; salaccensis, 922; trinervia, 1701; viridiflora, 1705.

(4212) HABENARIA ACUIFERA. This elegant species of habenaria is found in the Tavoy forests; and several other species of the same genus are scattered over the Tenasserim Provinces.—*Mason.*

(4213) HADIWICKE. A moderately hard, fine, close-grained, rather heavy Ceylon wood.

(4214) HÆMATITE, a name given to certain forms of the native Peroxide of Iron. When of a red colour it is called Red Hæmatite; and when brown, Brown Hæmatite.—*Eng. Cyc.*

(4215) HÆMATOXYLON, a genus of Plants belonging to the natural order *Fabaceæ* or *Leguminosæ*. It has 5 sepals united into a permanent tube. The petals, 5 in number, are scarcely longer than the sepals. There are no stamens; the filaments hairy at the base; the anthers without glands; style capillary. The legume is compressed, flat, lanceolate, acuminate at each end, 2-seeded; the sutures indehiscent; the valves bursting longitudinally.—*Eng. Cyc.*

(4216) HÆMATOXYLON CAMPEACHIANUM, Logwood, a tree common all over the West India islands. It is a low spreading tree, with a stem generally crooked and deformed,

seldom thicker than a man's thigh; the branches somewhat flexuose, terete, covered with whitish dots. In mountain and moist situations it is unarmed, but in the plains, or where the tree is stunted, it is furnished with spines below the leaves; the leaves 2 or 4 from the same point, (an irregular, tough, tubercular prominence,) pinnate, sometimes dividing in a bipinnate manner at the lowest pair of leaflets; the leaflets 4-paired, shortly stalked, obovate or obcordate; the racemes at first about the length of the leaf, afterwards, as the pods form, elongating; the flowers on pedicles half an inch in length, yellow, and slightly fragrant; the calyx deeply 5-parted; the lobes unequal, thrice membranous, purplish, deciduous; the tube short, green, and bell-shaped; the petals nearly equal, obovate, wedge-shaped at the base, scarcely longer than the sepals; the stamens alternately short, inserted (as also the petals) on the inside of the margin of the persistent tube of the calyx; anthers ovate; ovary lanceolate, compressed, 3-seeded; style projecting beyond the stamens and petals; stigma capitate, expanded; the pods compressed, flat, lanceolate, acuminate at both ends, 2-seeded, not opening at the sutures, but bursting longitudinally by a division passing down through both the valves.—*Eng. Cyc.* This tree has been lately introduced into India. It grows readily and seeds abundantly, but it remains to be seen whether it will attain a large size in this country. It is a promising tree and deserves attention.—*M. E. J. Report.* It is principally imported into Britain as dye wood, cut into short lengths. We chip, grind, and pack it into casks and bags, ready for the dyers, hatters, and printers' use, who esteem it as affording the most durable deep red and black dyes.—*Simmonds.* Logwood is noticed by Monardes for its medical uses. It is a powerful astringent, and may be employed as a substitute for kino, catechu, &c. In diarrhœa and dysentery the decoction is used with benefit.—*Eng. Cyc.* That grown in Jamaica is least valued, that of Honduras, Tobasco, and St. Domingo, fetches a somewhat higher price; but that imported from Campeachy direct, is the most esteemed. The annual imports into Liverpool are about 1,300 tons from Honduras, 100 from Tobasco and 1,800 from Campeachy.—*See Simmonds' Commercial Products, p* 484.

(4217) HÆMODORACEÆ. *Blood-Roots.* Under this name Dr. Robert Brown proposed, in the year 1810, to separate from the natural order *Iridaceæ* the genera *Hæmodorum*, *Conostylis*, *Anigezanthos*, *Phlebocarya Dilatris*, *Lanaria*, *Heritiera*, and *Wachendorfia*. He remarked that they are abundantly different, especially in being hexandrous, or in having the stamens, if only three in number, stationed opposite the petals, and in having the anthers opening on the side next the stigma; the habit was moreover different. This distinguished botanist mentioned in connection with his new order, without actually adding it *Xiphidium*. The latter genus has more recently been introduced along with *Hagenbachia* as an undoubted member, notwithstanding its having a superior ovary. All the species have equitant leaves, and perennial fascicled fibrous roots or bulb-like cormi; and there is also a general appearance of wool upon their flowers, in some cases to such an extent as to bury all the outer surface. The order may be considered a connecting link between *Iridaceæ* and *Liliaceæ*. One species, *Dilatris Heritieri*, yields a dyeing matter in its rhizoma. The species occur in North America sparingly, and at the Cape of Good Hope; several are described from the temperate parts of Australia, and some occur in Brazil and the Mascana Islands. The natives of Swan River live on the roots of some plants belonging to this order, especially of *Hæmodorum paniculatum* and *H. spiratum*, which are mild and nutritious when roasted, but acrid when raw. One of the most intense bitters known is *Aletris farinosa*. There are 13 genera and 53 species.—*Eng. Cyc.*

(4218) HAIR.

Hair, Dut.	Pelo, It.
Poil, Fr.	Pelles, Lat.
Haare, Haahaare, Ger.	Pelo, Sp.
Ball, Guz. Hind.	

Goats hair is largely exported from Bombay to England. It is much coarser than wool, and also inferior in other respects.—*Faulkner.* Bristles from the wild Boar and hair from the tail of the Elephant, are in use in India.

(4219) HAIR POWDER.

Poudre a poudrer, Fr.	Polvere di cipri, It.
Puder, Ger.	Polvos de peluca, Sp.

Hair powder is generally made from pulverised starch, and perfumed with various scents.—*Faulkner.*

(4220) HALCYONIDÆ, a family of Birds belonging to the Fissirostral Tribe, of the order *Insessores*, or Perching Birds, according to the system of Mr. Vigors. This family includes the beautiful birds known by the name of Kingfishers. The following characters are assigned by Mr. Swainson to the *Halcyonidæ*:—Wings rounded, not formed for rapid flight. Feet very feeble. Toes in pairs. He makes the family consist of the following genera and sub-genera:—Genus *Tamatia*, comprising *Tamatia*, Cuvier; *Capito*, Vieillot; *Lypornix*, wagler; *Monasa*, Vieillot; and *Brachypetes*, Swainson.—Genus *Halcyon*, Swainson, including *Dacelo*, Leach; *Halcyon*, Swainson; *Syma*, Lesson; *Todirampkis*, Lesson; and *Ceyx*, Lacepede.—Genus *Alceda*, Linnæus, comprehending *Alcedo*; *Ispida*, Swainson; *Tanysiptera*, Vigors; *Alcyone*, Swainson.—Genus *Lamprotila*, Swainson.—Genus *Galbula*, Linnæus (Brisson, we suppose, is meant; Linnæus [illegible] each genus.)—*Eng. Cyc.*

(4221) HALDIA MOORA. SINGIA MOORA. Roots brought to Ajmere mixed with haldi; they are acrid and poisonous, and are carefully separated.—*Ainsl. Med. Top. p.* 151.

(4222) HALENIA.

(4223) HALICORE, DUGONG.

Duyong, MALAY.

The Dugong is an inhabitant of the narrow seas of the Eastern Archipelago. Professor Owen denominated the Dugong of the archipelago *Halicore indicus*, in distinction from that of the northern coast of Australia, at a time when the former had not been ascertained to frequent (as a Dugong of some kind is now known to do) the Malabar coast and Gulf of Calpentyn in Ceylon; but it still remains to be proved that this is the true Malayan Dugong, however little reason there may seem to doubt it,—as there might equally have seemed little cause to suspect the distinctness of the *Halicore*.

(4224) HALL. A very soft, coarse, open-grained, light Ceylon wood, adapted only for very inferior work, and where durability is not required.

(4225) HALIOTIDÆ, a family of Gasteropodous *Mollusca*, to which the shells commonly called Ear-Shells, or Sea-Ears, belong. Mr. Swainson, in his first series of 'Zoological Illustrations,' observes, when writing on the Small-Holed Californian Ear-Shell (*Haliotis Californiensis*, 1820-21), that "the definitions given by conchologists up to that time were so imperfect that they had left our knowledge of these shells nearly the same as in the time of Linnæus. Seventeen species only are enumerated in Mr. Dillwyn's work; although thirty-four have fallen within my own observation during the last few months." Under the appellation *Stomatia*, he thus characterises the genus:—Shell pearly within, mostly coloured externally; suborbicular or long, generally ear-shaped and depressed. The spire, in most species, prominent, but not produced nor elongated; sometimes very small, marginal and inconspicuous. Aperture mostly longitudinal, in some species nearly orbicular, in others much elongated, always very large; its edges entire, united at the upper part, and scarcely modified or altered in form by any postion of the last volution. Volutions from two to four. Muscular impressions two, seldom distinct, nearly marginal, and in the open part of the shell. Mr. Sowerby goes on to state that *Stomatia* appears to be related to *Haliotis*, and is therefore rightly placed by Lamarck among his Macrostomes. One of its species is arranged by Linnæus, he adds, as a *Haliotis*, under the name of *H. imperforata* (Gmel). Mr. Sowerby does not pretend to discuss the question of their resemblance to Lamarck's Turbinaceæ; but only observes that in general form some of them approach very nearly to some of Lamarck's Monodontes. The *Stomatiæ*, he states in conclusion, are marine, and he says that all the species he has seen were brought from the East Indies and Australia. *Stomatia* has been found at a depth of seven fathoms, adhering to *Meleagrinæ* and corals. The following genera are referred by some writers to *Haliotidæ*, *Broderipia*, *Scissurella*, *Pleurotomaria*, *Murchisonia*, *Trochotoma*, *Janthina*.—*Eng. Cyc.*

(4226) HALISPONGIA. According to the structure and composition of the numerous species of Sponges, they may be divided into genera. If, in accordance with the observations of Dr. R. Grant, we consider sponges in three groups, one having a horny tubular structure, another containing calcareous spiculæ, a third containing siliceous spiculæ, we may adopt the three generic types, *Spongia*, *Calcispongia*, and *Halispongia*, of De Blainville. *Halispongia* is thus characterised;—Mass more or less rigid or friable, of irregular figure, porous, traversed by winding canals, which end in openings scattered over the surface; substance subcartilaginous, supported by simple siliceous spiculæ. The species exhibit various external forms, encrusting, branching, or foliaceous Dr. Fleming includes them under the title *Halichondria*.—*Eng. Cyc.*

(4227) HALMENDORA. A hard, fine, close-grained, heavy Ceylon wood.

(4228) HALMILILE. A rather soft, though fine, but not very close-grained, heavy Ceylon wood.

(4229) HALORAGACEÆ, *Hippurids*, a small group of Exogenous Plants, many of which inhabit watery places, and all of which have minute inconspicuous flowers. In consequence of the calyx being superior, the embryo without much albumen, and some of them having four petals, they are often considered to form a peculiar section of *Onagraceæ*, or if separated from that order, are at least stationed in the immediate vicinity of it. Upon this supposition, they are looked upon as an imperfect condition of the Onagraceous type, bearing the same relation to it as *Sanguisorbeæ* to *Rosaceæ*, *Chamælaucieæ* to *Myrtaceæ*, or *Mimoseæ* to other *Fabaceæ*. But in the present uncertainty regarding the true affinity of many natural orders of plants, we must not consider this a settled point. On the contrary, it is not improbable that *Haloragaceæ* constitute an imperfect form of the great Epigynous group of Exogens, of which *Onagraceæ* are only one of the members. What renders it peculiarly difficult to determine the real affinity of this little group is, that as it is now constituted, it offers striking modifications of development both in the organs of vegetation and those of fructification. While *Haloragis* has a stem with a complete vascular organisation, and regularly con-

structed leaves, *Myriophyllum* has its vascular system reduced to a rudimentary condition, and in some of the species the leaves themselves appear only in the form of filiform ramifications; and in *Hippuris*, the development of the vascular system of both stem and leaves is still further reduced. In like manner in the flowers, *Haloragis* has four petals, eight stamens, four stigmas, and four cells to the ovary; *Proserpinaca* has no petals, three stamens, three stigmas, and three cells to the ovary; and *Hippuris* has no petals, one stamen, one stigma, and but one cell to the ovary. This latter genus is a common plant in the marshes and meadows of England, where it is vulgarly called Mare's-Tail. Damp places, ditches, and slow streams in Europe, North America, Southern Africa, Japan, China, Australia, and the South Sea Islands are the resort of this order.—*Eng. Cyc.*

(4230) HAMAMELIDACEÆ, *Witch-Hazels*, a very small group of woody Exogenous Plants, characterised by having a superior calyx, a definite number of stamens half of which are usually sterile, a 2-celled ovary, and an embryo in the midst of horny albumen. There are only three genera in the gardens of England, *Hamamelis*, *Trichocladus* and *Fothergilla*. Some of the species are large forest-trees, affording good timber, but nothing is known of any other useful property in the order. The order is related to *Bruniaceæ*, *Cornaceæ*, and *Saxifragaceæ*. The species come from North America, Japan, China, and the central parts of Madagascar and South Africa. The kernels of *Hamamelis Virginica* are oily and eatable. The leaves and bark are very astringent, and also contain a peculiar acrid essential oil.—*Eng. Cyc.*

(4231) HAMAMELIS CHINENSIS, a plant hitherto only known as a native of China though it grows on the Jyntia Hills; this, the *Bowringia*, and the little *Nymphæa*, are three out of many remarkable instances of our approach to the eastern Asiatic flora.—*Hooker, Him. Jour. Vol.* II, *page* 318.

(4232) HAMPALEDE, a rather soft, fine, though open grained, heavy wood, of Ceylon.

(4233) HAMS.

Hammen, Dut.	Proscintti, It.
Jambons, Fr.	Presuntas, Port.
Schinken, Ger.	Okoroku, Rus.
Ham, Guz. Hind.	Jamones, Sp.

The thighs of the Hog cured, smoked, and dried.—*Faulkner.*

(4234) HAMAYOON. In the vicinity of Delhi is the ancient yet well preserved Mookubah or tomb of the Emperor Hamayoon. It is upwards of 300 years old, and all that seems to bear features of decay is the external coating of cement.—*French's Tour, p.* 14.

(4235) HANDKERCHIEFS. Handkerchief pieces form a considerable article of manufacture and traffic in Southern India. At the Madras Exhibition of 1857, Handkerchiefs, colored, Madras; red, Sydapet; and from Ventapollam, were much admired for the harmony and richness of the colors, and the superiority of texture.—*M. E. J. R.* Putcha Ramalinga Chetty sent from Nellore Handkerchiefs (pocket), Jean Cambric Muslins, *watered*, (Rajabundar) and what is called unbleached Drill, but it was good Jean. These manufactures deserved unqualified approbation, especially the watered Cambric, which was exceedingly well done. The Cotton Fabrics of Nellore were most interesting, excellent in quality and of great variety from the coarsest material to that which is very superior, and deserved in the opinion of the Jury marked notice. —*M. E. J. R.*

(4236) HANDKERCHIEFS OF SILK, are manufactured chiefly in Bengal and are known in the market as "Bandanah," "Korah," and "Chapah." They are generally figured and of different colours. They are exported chiefly to the Burmese Territories and sold at from 1½ to 5 Rupees each. Those of Madras manufacture are ordinary, always red in colour and chiefly used by the inhabitants. The coloured handkerchiefs manufactured at Ventapollem on the coast, which are well known in foreign markets, are deserving of notice. These were formerly highly prized for their superior qualities and colours, but they have been driven from the markets by the Madras and Pulicat manufactures, which the community prefer for their superior qualities and colours. Handkerchiefs of Madras of these superior kinds are sold at 1¾ rupee each, and inferior sorts at 4 annas to 12 annas; the colour of the last description is very perishable. The ordinary colour of the Madras Handkerchiefs is red. Almost all the natives, Mahomedan and Hindoo, prefer them to those of other countries. Handkerchiefs Silk, for the Head. The principal site of their manufacture is Seringapatam in Mysore; they are of superior quality and of red and pink colours, they are in squares of 6 cubits, and are in consequence of their gold lace borders, sold at 35 to 100 Rs. each.

(4237) HANS-RAJ. Paraisoo-oosa. Leaves of a common plant found near water at Ajmeer; are heating and febrifuge.—*Gen. Med. Top. p.* 137.

(4238) HAR, Harra, from Terminalia chebula, and other species, three in number, comprise all the discarded myrobalans of our old pharmacopæias. The myrobalans as brought into Cashmere from Delhee and Harowtee, Hindustan and the Dukan, are of four kinds namely; *Gurul harra.*—Astringent and purgative: used in mesalihs: given in medicine to children: four seers for one rupee. *Juwal harra.*—Used in the same way: eight seers for one rupee. *Chaipel harra*, used only in dyeing, ten seers for one rupee. The whole are

much used in dyeing. According to the size of the myrobalan, its value augments, so that a very large one may be worth one hundred rupees or more, the natives believing that the very large ones have the virtue of causing purging by being merely retained in the hands.—*Genl. Med. Top. p.* 186. The Har or Harra, is, says Dr. Irvine, one among the articles of the native materia medica than which none is more vaunted. It is considered to possess wonderful general deobstruent and purgative qualities &c. &c., while those who thus belaud it, are apparently not aware that this is the chebulic myrobalan (Terminalia chebula) of English pharmacopæias of the sixteenth century and long since deservedly neglected.—*Genl. Med. Top. p.* 153.

(4239) HARDWARE.

Iseukramvarer, DAN.	Chincaglio. IT.
Yzerkramery, DUT.	Quincalharia, PORT.
Clinquaillerie, Quincaillerie, FR	Mjeloizchnue towarii, RUS.
Kurze waaren, GER.	Quinquilleria, SP.
Looah-kam, GUZ. HIND.	Jarnkram, SW.

Includes every kind of goods manufactured from metals, comprising iron, brass, steel, and copper articles of every description. Birmingham and Sheffield are the principal seats of the British hardware manufacture; and from these places immense quantities of knives, razors, scissors, gilt and plated fire-arms, &c., are supplied, as well for exportation to most parts of the world, as for home consumption.—*McCulloch, Faulkner.*

(4240) HARDWICKIA BINATA.

Acha or Alti marum, TAM.

This elegant tree is found indigenous on the mountains on the Coast of Coromandel, where it grows to a large size and yields a timber of an excellent quality for a variety of uses.—*Rohde. M.S.S. Hardwickia binita* is a most elegant leguminous tree, tall, erect, with an elongated coma, and the branches pendulous. These trees grow on the hills of the Soane valley in a shallow bed of alluvium, enclosing abundance of agate pebbles and kunker, the former derived from quartzy strata.—*Hooker. Him. Jour. Vol.* I. *page* 50.

(4241) HARMALA RUTA. PEGANUM HARMALA. Ruta sylvestris.

Harka, CAN.	Viragu, TAM.
Kodar, HIN.	Arkalu, TEL.

Grows plentifully at Lahore. The ruins of the old city are covered with this weed and Asclepias gigantea. The former (called Hoormul) is, at Lahore, looked upon as the plant devoted to the Pariahs (the inferior cast, the sweepers) yet though a Sikh or Hindoo, would not touch Hoormal; the seeds are in common use among the natives who therewith fumigate the rooms of the wounded. The natives fancy that a person suffering from any discharge, as hœmorrhoids, the monthly courses, &c., is unclean, and that the exhalation proceeding from such person may be prejudicial to the wound, therefore it is customary on the entrance of every stranger to strew a few grains of hoormal upon a charcoal fire. The natives (with the exception of Sikhs and Hindoos) use these seeds internally against weakness of sight and retention of urine.—*Dr. Honigberger, page* 284.

(4242 HART'S EAR, [illegible]DER LEAVED CACALIA. Cacalia kleinia.

Lisanul-Saur, ARAB.	Irminakullie, TAM.
Gowzahan, GUZ. HIND. PERS.	Yenapootoo nalikeh jemmoodoo, TEL.

These leaves resemble the tongue of the cow (hence its Asiatic name), the stalks are prickly, and covered with white spots. While fresh, the leaves have a strong smell like hemlock; and are given by native practitioners in the form of decoction in rheumatism, syphilis, leprosy, and in all other cases in which sarsaparilla is usually employed by European doctors. It is brought to Bombay from the Persian Gulf, and is procurable in most native druggists' shops throughout India.—*Faulkner.*

(4243) HASSELTIA, a genus of Plants belonging to the natural order *Apocynaceæ*. It has a 5-parted permanent calyx; a corolla with the tube contracted in the middle; the throat naked; the limb campanulate, 5-parted, contorted. The stamens are inserted in the throat. Anthers large, cuspidate, callous at the back, adhering to the stigma; the ovary double, surrounded by a fleshy ring; styles 2; stigma clavate; follicles 2, distinct, and long; seeds with a stipitate coma at the lower end.—*Eng Cyc.*

(4244) HASSELTIA ARBOREA is found in Java, near Tjampiam. It is a handsome tree, with oval leaves, rather acute at each end, smooth above, paler and a little downy on the under side. The flowers are large, yellowish-white, in axillary fascicles. In Java the milk obtained from the trunk by incision, mixed with honey and reduced with boiling water, is employed as a powerful drastic for destroying the tape-worm; it is however apt to produce inflammation of the intestines, and in some cases has proved fatal. Lindley, *Flora Medica.—Eng. Cyc.*

(4245) HATS.

Hoeden, DUT.	Cappelli, IT.

Ghans, Guz. Hind.	

Any kind of grass, cut and dried for the food of horses, cattle, &c.—*Faulkner.*

(4247) HAZEL NUT.

Bindick, Beng.	Avellane, Lat.
Noisettes Aveilenes, Fr.	Fendook, Pers.
Haselnusse, Ger.	Avellaas, Port.
Fendook, Guz. Hind.	Avellanas, Sp.
Naccinole, Aveline, It.	

The fruit of different species of *Coryli* or hazel. The kernels have a mild, farinaceous, oily taste, ageeable to most palates. A kind of chocolate has been prepared from them; and they have been sometimes made into bread. They are grown in England, France, Portugal, but chiefly Spain. They are also produced abundantly in the Himalayas.—*McCulloch.* Hazel nuts are imported into Bombay from the Persian Gulf.—*Faulkner.* According to the English Cyclopædia, the Hazel-nut is the fruit of the wild bush of *Corylus Avellana*, unchanged and unimproved by cultivation. It differs from the domesticated varieties only in being smaller and rather more hardy.—*Eng. Cyc. Vol.* III. *page* 31.

(4248) HEAD CLOTHS, COTTON, or Roomals, are manufactured in the Madras Districts: they are always in squares of 5½ and 6 cubits with Lace Borders and are always Red Coloured, printed with white spots. These are worn by Hindoos as turbands and are valued at from 8 Rupees to Rs. 250.

(4249) HEAVY SPAR. Sulphate of Baryta. *F.* Sulfate de Baryte. G. Schwefelsaures Baryt. Sulphate of Baryta (Ba O, S O_3=117), or Heavy Spar, is more abundant as a mineral than the Carbonate. The finest specimens have been obtained from Dufton in Cumberland: Dr. Royle found it on the Himalayas, near the Convalescent depot at Landour. (*v.* Illustr. Himal. Bot. p. xxxiii.) *Prop.* Heavy Spar may be found massive or crystallized, of a foliaceous or lamellar structure; white-grey, or with a reddish hue; often translucent; heavy: Sp. Gr. 4·41 to 4·67; without odour or taste; insoluble in water. Its crystals are often bevelled tables or flat prisms of six sides, and may be divided into right rhombic prisms.

(4250) HEBENSTREITA. Selaginaceæ.—This is a genus of undershrubs the flowers white, grown in common garden ground.

(4251) HEBRADENDRON, a genus of Plants belonging to the natural order *Clusiaceæ*. It was established by Professor Graham of Edinburgh, for the Gamboge-Tree of Ceylon. The gamboge of commerce is known by the names of Ceylon and Siam gamboge. The gamboge of Siam is in cylinders, either solid or hollow, usually called pipes: it is supposed to have this form from being so rolled, or from being poured into the hollow of bamboos, according to Lieutenant White, in his 'Visit to Cochin China.' It is usually of the best quality, but Mr. Pereira has shown that some very impure is occasionally in the form of pipes. As this pipe-gamboge is usually exported from Singapore, it has been doubted whether it was actually the produce of Siam; but specimens from Mr. G. Swinton, which were sent to him direct from Siam, when he was chief secretary of the Indian government, as the produce of that country, are identical with the best pipe-gamboge of commerce. The only information respecting its preparation which we possess, is that given to Kœning by a Catholic priest, who officiated as such to the Catholics of Cochin China, and who stated that the inspissated juice obtained from breaking the leaves and young shrubs, as well as the fragrant lignum aloes, is given as a tribute to the king of Siam by the Christians residing there. The tree must therefore be common, and probably near inhabited places, and therefore very likely to be *Oxycarpus Cochinchinensis* of Loureiro (now referred to the genus *Garcinia*), who names it from its acid fruit, and describes it as cultivated in Cochin China. Specimens of a plant, something similar to this in the form of its leaves, given by Mr. Malcolmson, were collected by him in Rangoon, which he thought might be the gamboge plants, as it contained a yellow purgative juice in the rind of its fruit. Dr. Graham thinks that the Siam plant may be a nearly allied species of the same genus as the Ceylon plant. The Ceylon gamboge is usually considered inferior; that which forms an article of commerce no doubt is so; and we have been informed by one of the principal merchants of Ceylon that, finding the gamboge there very cheap, he had been induced to purchase and send it to England, but had not been able to sell it from its inferior quality. No doubt however some of very excellent quality is produced in Ceylon by the tree which has been called *Hebradendron cambogioides*, and Mrs. Colonel Walker describes it as "brilliant and excellent," and "as good for water-colour drawings as any she ever used." Dr. Graham ascribes its inferiority to want of care in preparing the article for market; though it is yet doubtful whether the Ceylon gamboge of commerce is all yielded by this tree; but Mrs. Walker on one occasion, in passing through a forest of these trees, saw all of them with the bark cut off in various places. Dr. Christison has shown that there is all but an identity of composition with that of Siam; and its medicinal effects are precisely the same, as proved in Ceylon by Dr. Pitcairn, and by Drs. Graham and Christison in Edinburgh. The plant, though new named, is far from being new. Dr. Graham considers it to be identical with the *Carcapuli* of Herman, the

Cambogia gutta of Linnæus, the *Garcinia morella* of late authors, and the *Stalagmitis cambogioides* of Moon's 'Catalogue of Ceylon Plants.' The last name might have been retained, as it was originally intended for it, had it not been discovered by Mr. Brown that the specimens in the 'Banksian Herbarium' collected by Kœnig, and from which Murray's character of the genus and species was established, consist not of one, but of two distinct plants, the flowers of *Xanthochymus ovalifolia* being stuck by sealing-wax upon a branch of what appears to be this Ceylon plant. The genera *Stalagmitis* and *Xanthochymus* are therefore one genus, as was previously inferred by Cambessodes, who has retained for it the former, as the prior name. The genus *Hebradendron* has diœcious flowers, the male having the calyx membranaceous, 4-sepalled, persistent; corolla 4-petalled; stamens monadelphous; column 4-sided; anthers terminal, opening by the circumcision of a flat and umbilicate terminal lid. The inflorescence of the female tree is similar to that of the male, the flower white and a little larger, with a germen precisely in miniature of the fruit, and surrounded (like it) with several (ten?) abortive stamens. The berry is many (4-) celled; cells 1-seeded, surrounded at the base with some free abortive stamens, crowned by a lobed and muricated sessile stigma; cotyledons fleshy, united; radicle central, filiform; trees with entire leaves.

(4252) HEBRADENDRON GAMBOGIOIDES, (Graham.) *Syn.* Cambogia Gutta, L Mangostana Morella, (Desroup.)

Gokatu, or Kana goraka, Cing.

The species called *H. cambogioides* forms a moderate-sized tree, with the leaves obovate, elliptical, abruptly sub-acuminate; the male flowers clustered in the axis of the petioles on short single flowered peduncles; sepals yellow on the inside, yellowish-white externally; petals yellowish-white, red on the inside near the base; berry about the size of a cherry, round, with a firm reddish-brown external coat and sweet pulp; ripe in July. It is called in Ceylon Kana (eatable) Goraka. *G. cambogia* is called simply Goraka. The gamboge is used by the natives both as a pigment and medicinally. Mrs. Walker describes it as being collected by cutting pieces of the bark about the size of the palm of the hand early in the morning. The gamboge oozes out in a semi-liquid state, but hardens on exposure to the air, and is scraped off by the collectors next morning. This tree is found in various parts of Ceylon, but not very abundantly near Colombo. In a tour through different parts of the island, Mrs. Walker writes: "We found the Ceylon Gamboge Tree several times in forests distant from the habitation of man, which proves the tree to be indigenous." Colonel Walker writes to Dr. Wight, that "it is found in great abundance along the western and eastern coast in the neighbourhood of Battocola, but it also grows inland, where it could not have been planted by the Dutch. Its favourite abode seems to be low sandy ground, as about Kanderaane, Negombo, and towards Chilaw; also 100 miles inland, at so high an elevation as 2000 feet above the sea." *Garcinia elliptica*, a native of Silhet and *G. pictoria*, of the Wynaad district, are thought to be other species of this genus. Besides the above species there is probably another belonging to the same genus, or to the same group of a larger genus, which appears to yield a very good kind of gamboge. It is the *Garcinia pictoria* of Roxburgh.

(4253) HEBRADENDRON PICTORIUM of Lindley and other botanists. It is a tall tree, about 60 feet high, of a conical shape, and very full of branches. The bark is pretty thick, scabrous and ramous on the outside, of a dark ferruginous colour, intermixed with many yellow specks, and through its substance, particularly on the inside, considerable masses of gamboge are found. The young shoots are somewhat angular, smooth polished, of a deep green colour. The leaves are opposite, short petioled, oblong, ventricose, rather acute, entire, smooth on both sides, and of a firm texture, from 3 to 4 inches long, by 1½ or 2 inches broad. The calyx consists of two unequal pairs of concave obtuse leaflets, permanent. Petals 4, oval, longer than the calyx. Anthers from 10 to 15, oblong, 2-lobed, and seemingly fertile. Ovary superior, round, 4-celled, with one ovule in each, attached to the axis a little above its middle. The berry is the size of a large cherry, oval, smooth, very slightly marked with four lobes, crowned with the sessile 4-lobed verrucose permanent stigma. Roxburgh says he received frequent samples of the gamboge of this tree from a correspondent at Tellicherry, and uniformly found it, even in its crude unrefined state, superior in colour while recent, but not so permanent as that from China. The tree grows on the highest parts of Wynaad in India. (Lindley, *Flora Medica*; Royle, *Materia Medica.*)

(4254) HEDERA, a genus of Plants belonging to the natural order *Araliaceæ*. The calyx has an elevated or toothed edge. The petals 5 or 10, not calyptrate and cohering; stamens 5 to 10: styles 5 to 10, converging or consolidated: the berry 5 or 10-celled.—*Eng. Cyc.* Dr. Wight gives H. acuminata 1062; Jackiana, 1062; (P.) obovata, 1011-12; (P,) racemosa, 1015; (P.) rostrata, 1013-14; trifoliata, 307.

(4255) HEDERA HELIX, Ivy, is a common plant all over Europe, clinging to trees and walls. It has a stem climbing with root-like fibres; leaves coriaceous, smooth, shining, 5-angled, or 5-lobed, the upper or old ones ovate and acute; umbels simple and downy; leaves austere and bitter: berries bitter, aperient, and emetic. It is mentioned as a sudorific, and was once reputed to prevent drunkenness and to dissipate the ef-

fects of wine. The berries are black at maturity. The flowers are yellowish, and appear late in the season, and, in consequence, are much resorted to by bees and flies when little other food is to be had. It is found commonly wild in England, and is dispersed through many distant parts of the Old World, lying between the Canaries and Europe on the west, and the northern parts of China on the east. In the Canaries it acquires its largest size, being what is called in English gardens the Irish or Giant Ivy, which grows so much faster than the European form. In the north of India, and indeed occasionally in Italy, the berries, instead of being black as with us, are bright yellow, and it is supposed that this is more particularly the *Hedera* of the Roman poets. The leaves vary much in form, and there is a kind which never runs or creeps upon other plants, but merely forms a compact bush.

(4256) HEDERA UMBELLIFERA is a native of Amboyna. It has a shrubby unarmed stem; leaves on long stalks, lanceolate acuminate, distantly serrated; peduncles 16, trifid and umbellate; partial umbels capitate, roundish. It yields a blackish or dull-brown resin with a very powerful aromatic camphorated smell. It is called 'Sarura' in Amboyna. There are 50 species of Ivy enumerated, all of which are of easy culture.—*Eng. Cyc.*

(4257) HEDYCHIUM, SCITAMINEÆ.—Garland Flower, Wight gives Hedychium, (Vol. VI flavescens, page 15) cernuum, 2011; coronarium, 2010; 2008-9; scaposum, 2030; venustum, 2012. A very fragrant species of hedychium with long narrow petals, and an epiphytic habit is often seen in Tavoy. The species is not described in any books to which Mr. Mason had access. —*Mason.*

(4258) HEDYCHIUM CORONARIUM.—The garland flower, a species of hedychium, but regarded by Europeans as a lily, is much cultivated by both natives and foreigners. The yellow and white varieties are both common. "This to me," says Roxburgh, "is the most charming of all the plants of this natural order that I have met with; the great length of time it continues to throw out a profusion of large, beautiful, fragrant blossoms, makes it particularly desirable."—*Mason.* These plants are natives of India, and only require a light rich soil: the flowers are fragrant, colours, orange, scarlet, yellow and white; they are increased by dividing the roots.

(4259) HEDYCHIUM SPICATUM. The root is called *seer, ruttee, kupoor kuchree;* the plant, *idhuoul,* Hind. The root is fragrant, warm, and aromatic. Royle, to whom is due the merit of tracing the true source of the root, thinks it may probably be the *ritte,* or *lesser galangal* of Ainslie.—*O'Shaughnessy, page* 652. Capoor kutchery is the root of this plant which grows in China, it is about half an inch in diameter, and is cut into small pieces and dried for exportation; has internally a whitish colour, but externally it is rough and of a reddish color; it has a pungent and bitterish taste, and a slight aromatic smell. It is exported to Bombay, and from thence to Persia and Arabia; it is said to be used in perfumery and for medicinal purposes, and also to preserve clothes from insects.

(4260) HEDYOTIS. An attractive purple-flowered shrub, a species of hedyotis is multiplied in some sections of Tenasserim.—*Mason.* Dr. Wight in Icones gives Hedyotis (A.) affinis, 1030; (D.) articularis, 1028; deltoidea, 1033; (D.) Lawsoniæ, 1026; Deschenaultiana, 1039; (A.) monosperma, 1031; plantaginifolia, 1029; racemosa, 312; ramosa, 822; (D.) stylosa, 1027; (D.) verticillaris, 1029.

(4261) HEDYSARUM. (from ἡδύσαρον, the Greek name of the *Coronilla Securidaca*), a genus of Plants belonging to the natural order *Leguminosæ.* It has a 5-cleft calyx, with the segments linear-subulate and nearly equal; the corolla with a large vexillum, and obliquely truncate, keel much longer than the wings; the stamen is diadelphous; the legume of numerous flat, orbicular or lenticular, regular 1-seeded joints, which are connected together in the middle, and therefore the sutures are convex on both sides. The species are herbs or under-shrubs, with unequally pinnate leaves, axillary with simple peduncles, and bearing racemose spikes of large, purple, white, or cream-coloured flowers. The old genus *Hedysarum* has been subdivided into many smaller genera. The saintfoin, *H. onobrychis* of older writers, now forms the genus *Onobrychis,* which differs from *Hedysarum* in the legumes consisting of many joints, not of one joint, as in that genus. *H. lineare* is used in Cochin China as a stomachic, and *H. alpinum* is used in Siberia for the same purpose. The *H. sennoides* of Willdenow, now *Ormocarpum* sennoides, has a root which is used in India as a tonic and stimulant. The *H. Alhagi* of Linnæus is the *Alhagi Maurorum* of recent writers. It is a spring shrub, and from its branches exudes a sweet substance like manna. *H. tuberosum* of Roxburgh, *Pueraria tuberosa* of De Candolle, grows in the Circar Mountains. The roots are used by the natives as poultices for swellings of the joints.—*Engl. Cyc. Vol.* III *p.* 55. Of the genus Hedysarum, Dr. Wight, in Icones, gives the following species alopecuroides, 290; auriculatum, 298; biarticulatum, 419; bracteatum, 268; cephalotes, 373; collinum, 272; crinitum, 411; diffusum, 409; Gangeticum, 271; gyrans, 294; hamosa, 284; lagenarium, 299; lagopoides, 289; latifolium, 270; Neli,—tali, 405; patens, 407; pictum, 411; procumbens, 408; pulchellum, 418; purpureum, 406; quinqueangulatum, 293; recurvatum, 374; reptans, 291; sennoides, 297; strobiliferum, 267; triflorum, 292; tuberosum, 412; vespertilionis, 285; viscidum, 286.

(4262) HEDYSARUM ALHAGI, Lin.

Juansa, Hindoo.

Juansa is the Hindoo name of a prickly bush of which Tatties are sometimes made in Upper Hindoostan.—*Ains. Mat Med p.* 176.

(4263) HEDYSARUM JUNCEUM, Rush-Stemmed Hedysarum. Grows in vast quantities in Shekhawattie and elsewhere, near Jaepoor, the small branches are sweet and eaten by camels and other cattle. This becomes a considerable bush, and has no thorns.—*Gen. Med. Top. p* 205.

(4264) HEDYSARUM LINEARE is used in Cochin China as a stomachic, and *H. alpinum* is used in Siberia for the same purpose. The *H. sennoides* of Willdenow, now *Ormocarpum sennoides*, has a root which is used in India as a tonic and stimulant. The *H. Alhagi* of Linnæus is the *Alhagi Maurorum* of recent writers. It is a spiny shrub, and from its branches exudes a sweet substance like manna. *H. tuberosum* of Roxburgh, *Pueraria tuberosa* of De Candolle, grows in the Circar Mountains. The roots are used by the natives as poultices for swellings of the joints. All the species of the genus *Hedysarum* may be cultivated. They thrive in a light rich soil; the perennial sorts may be increased by dividing the roots; and the seeds of the annual species should be sown in an open border.

(4265) HEDYSARUM SENNOIDES. Moorungy Root. Willd.

Caat Moorangy vayr, Tam.	Adivie Moonga vayroo, Tel.
Junglie Moonghie ke jurr. Duk.	Kanana (shigroo,) Sans.

This root, which possesses a considerable degree of warmth, is prescribed, as a tonic in certain cases of fever, it is also supposed to be a valuable remedy in rheumatic affections of long standing given in decoction. With the bark of the root, ground small, and mixed with Gingilie oil, is prepared a liniment which the Vyteans recommend as an external application in paralytic complaints and in lumbago.—*Ain's. Met. Med. page* 74.

(4266) HELENIUM MEXICANUM. Most of the species are well adapted for borders, they are tallish growing plants, and all with yellow coloured flowers, grow in any common soil, natives of North America chiefly.—*Riddell.*

(4267) HELIANTHEMUM, a genus of Plants named from ἥλιος, the sun, and ἄνθος, a flower, because the flowers open with the rising of the sun, and fall with the setting of the sun in the evening. This genus belongs to the natural order *Cistineæ*, or *Cistaceæ*, and the species were at one time included under the genus *Cistus*, but they differ materially in their characters. There are about 150 species enumerated, which are distributed in various parts of the world. They are chiefly found in the south of Europe, the north of Africa, and a few species in America. The calyx consists of 5 sepals, the 2 exterior ones small or wanting, 5 deciduous petals, numerous stamens, and 3-valved capsules. The flowers are yellow, red, or white, and are very elegant; none of the species possess any available property in the arts or medicine, but they are extensively cultivated on account of their very beautiful and ornamental appearance.

(4168) HELIANTHEMUM BREWERI is a British plant. It has obtuse obovate leaves, without stipules; racemes without bracts.

(4269) HELIANTHEMUM CANUM, the Hoary Sun-Rose, is distinguished by its shrubby appearance, without stipules, and having terminal bracteated racemes. The flowers are yellow and small. It is a native of the south of France and Germany, and is rarely found in Great Britain.

(4270) HELIANTHEMUM GUTTATUM, is an erect herbaceous plant with oblong lanceolate or linear leaves, the racemes without bracts, and the stigma subsessile. The flowers are yellow, with a deep red spot at the base of each petal, it is a native of France, Italy, Spain, Portugal, and Turkey, and is found in Anglesey and Jersey in Great Britain, but is a very rare plant.

(4271) HELIANTHEMUM POLYFOLIUM is found in Devonshire and Somersetshire. It is a hoary plant, with stellate pubescence; the leaves opposite, ovate-oblong, or oblong-linear; the sepals tomentose, inner ones obtuse. Almost all the species of *Helianthemum* are elegant plants, of hardy growth, and easily cultivated. They grow best in Britain. They are generally used for planting on rock-work, soil, common garden.

(4272) HELIANTHEMUM VULGARE, the Common Rock-Rose, is a procumbent shrub, with stipules, bracteated racemes, the style larger than the ovarium, and bent at the base. The flowers are yellow, and bloom from May to September. It is a native of Europe, and is found in Great Britain in dry hilly pastures. There is a very beautiful variety with double pale yellow flowers, which is much cultivated by florists. The stamens, if touched in the sunshine, spread slowly, and lie down upon the petals.

(4273) HELIANTHUS ANNUUS: Sun Flower.

Suraj mukhi, Hind.

Very common in gardens.—*Gen. Med. Top. page* 206.

(4274) HELIANTHUS TUBEROSUS: Jerusalem Artichoke. Cultivated in gardens. —*Gen. Med. Top. page* 206.

(4275) HELICIDÆ, a family of Gasteropodous *Mollusca* to which the land Shell-Snails are referred. The *Helicidæ* are most widely diffused over the surface of the earth; scarcely any countries but those where the climate is surpassingly rigorous are without some species

the family. Many of the shells are strikingly autiful in form and colour, and these are most the inhabitants of intertropical countries. me of the genera (*Achatina*, for instance) at- in a very large size, and lay eggs in proportion, *elix aspersa*, the common Garden Snail, is stributed over a large portion of the globe. It found, for instance, at the foot of Chimboraço, the forests of Guyana and Brazil, and on all e coasts of the Mediterranean in Europe, Asia, d Africa. *Helix pomatia* has been naturalised Britain, and is still found in some countries. ıe first importation is attributed by some to r Kenelm Digby. Merrett mentions it as a itish inhabitant before his time. A moist and ther warm state of the atmosphere seems most ngenial to this family. To avoid great, dry heat ey get under stones, under old trunks of trees, ıves, &c., and some of the species will burrow to the earth for protection against it. A shower ll bring them forth in such numbers sometimes, e smaller species especially, as to induce the lief in some cases that it has been raining ails. Most of the species hybernate. Utility Man.—The *Helicidæ*, from their voracity, are ry injurious to the agriculturist and horticul- rist; but there can be no doubt that the larger ecies are good food. We know that they were favourite dish with the Romans, who had their Cochlearia,' where they were regularly fatten- with new wine boiled down and meal (sapa et rre, &c.) (Pliny, 'Hist.,' lib. ix. c. 56.) *Helix matia* is used as food in many parts of Europe ıring Lent, and the snails are kept in an escar- toire (snaillery), which is generally a large ace boarded in, having the floor covered half a ot deep with herbs, where the animals fatten. any are familiar with the passage in Pliny (loc. t.), who, on the authority of Varro, relates the credible size to which the art of fattening had ought the snails. There must, one should ink, be some mistake in the text, which says— Cujus artis gloria in eam magnitudinem per- icta sit, ut octoginta quadrantes caperent sin- ılarum calices." Pennant, referring to this and Varro ('De Re Rustica'), says, "If we should edit Varro, they grew so large that the shells some would hold ten quarts! People need not mire the temperance of the supper of the unger Pliny ('Epist.,' lib. i.; Epist., xv.), ıich consisted of only a lettuce a-piece, three ails, two eggs, a barley cake, sweet wine and ow, in case his snails bore any proportion to ose of Hirpinus."

(4276 & 4277) HELLEBORUS NIGER, OR LACK HELLEBORE. *Syn.* Melampodium.

Katuroum, SANS.	Kherbeck, ARAB.
Kalikootkie, DUK.	Kerbeck seeah, PERS.
Kherbeck, Kurbec- aswad, ARAB.	Cuddoo, Kali Koot- kie, GUZ. & HIND.
Calurana, CYNG.	Helleborus Niger, LAT.
Kali-kootkie, DUK.	
Neiswurtel, DAN.	Kherbeck Seeah, PERS.
Hellebore, FR.	Katurohina, SANS.
Schwartz Neisswar- gel, GER.	Kodagaroganie, TAM.
Hellboro, PORT.	Katookaroganie, TEL.

Under the native names two kinds of hellebore are brought from Nepaul and the Red Sea, and which are commonly met with in the Indian bazars They are much used by farriers, and occasionally by native practitioners as a powerful cathartic in maniacal and dropsical cases. The roots of one kind occur in pieces of four to six inches, are black all through their substance, externally of a grapish colour, with numerous joints. The second variety is in similar pieces, but of a whiter colour internally. Black hellebore is indigenous to the Alps, Pyrenees, and Apennines, and is also cultivated in Great Britain. White hellebore grows in Switzerland, and the mountainous parts of Germany. The roots of both plants are used in medicine.—*Faulk.* Under these native names two kinds of Hellebore root are brought to India from Nipal and from the Red Sea, and are commonly sold in the bazars; they are much used by farriers, and occasionally by the native practitioners as a powerful cathartic in maniacal and dropsical cases.—*O'Shaugnessy, page* 168.

(4278) HELICHRYSUM MACRANTHUM. Many of this genus are much admired for their very lasting and brilliant colours, they grow well in a rich soil and are easily cultivated by cuttings taken off at the joint. Some species seed freely and are found very abundant at the Cape of Good Hope.—*Riddell.*

(4279) HELICTERES ISORA. SCREW PLANT. Lin.

Maror-phalli, HIND.	Merowrie, HIND.
Valumbirikai, TAM.	Avertunnie, SANS.
Avurtunnie, SANS.	

This is a singular looking, contorted capsule, consisting of five fibres closely twisted in the shape of a screw. It is of a various length, from one inch to two and a half. A liniment is prepared with the powder of it, which is supposed to be a valuable application in cases of offensive sores inside of the ears. The Teloogoo name of the Valumbirikai, is Noollie tudda. Rheede says the juice of the root is a powerful stomachic. See Hort. Mal.—*Ain's. Mat. Med. page.* 112. The powder of the fruit has also been used in griping pains of the bowels, but solely because the twisted fibres of the capsule were considered to stamp it as a remedy, according to the ancient doctrine of signatures.—*O'Shaughnessy, p.* 228.

(4280) HELICTIS (Gray), a genus of *Mammalia* belonging to the order *Carnivora*. The species inhabit eastern Asia, and have the general appearance and colouring of *Mydaus*, combined with a dentition resembling that of *Gulo* or *Mustela*, but differing from both the latter genera in the large internal lobe of the upper carnivorous

tooth. The genus is thus characterised by Dr. Gray :—

Incisors (primores) $\frac{6}{9}$: canines (laniarii) $\frac{1-1}{1-1}$; molars $\frac{5-9}{5-6}$

Head elongated, feet short; soles of the feet nearly naked to the heel; toes 5—5; claws strong, the anterior ones long and compressed. Tail cylindrical and moderate. There are two species, *H. moschata* from China, and *H. Nepalensis* from Nepaul.

(4281) HELIOPHILA. CRUCIFERÆ.—A genus of pretty annuals, natives of the Cape of Good Hope, colours, purple, blue, violet and white, raised by seed, in pots, and may afterwards be placed out in borders.—*Riddell.*

(4282) HELIOTROPE. [BLOOD-STONE.]

(4283) HELIOTROPE. H. PERUVIANUM. —Should be grown in a soil more approaching to sand than clay, easily cultivated in pots, or the flower beds, propagated by cuttings in sand under glass. They require to be protected from the hot winds.

(4284) HELIOTROPIUM, (from ἥλιος, the sun, and τροπή, a turning), a genus of Plants belonging to the natural order *Ehretiaceæ*. It has a salvershaped corolla, with the throat usually naked, but in some species bearded; the segments of the limb furnished with a single fold or a tooth between each; the stigma sub-conical; the carpels 4, 1-celled, combined, closed at the base, without any manifest receptacle. The species are annual or shrubby plants, with alternate leaves, and circinate spikes of small blue or white flowers. Wight gives, in Icones, Heliotropium brevifolium, 1389; Co-romandelianum, 1388; linifolium, 1391; Malabaricum, 1387; marifolium, 1390; Rottleri, 1392; scabrum, 1389-90; supinum, 1387; tenue, 1391; Zeylanicum, 892, 1386.

(4285) HELIOTROPIUM INDICUM. INDIAN TURNSOLE.

Hattee shoora, BENG. | Srihastini, also Bhoo. roomdi, SANS.
Siriari, HIND.

Plant slightly bitter, juice of the leaves applied to painful gum-boils and to repel pimples on the face—also used in inflamed or excoriated tarsi. A very common plant. In Jamaica it is used with castor oil to relieve the pain of scorpion stings, and in the treatment of hydrophobia—*O'Shaughnessy, page* 497.

(4286) HELIX (Linnæus), a genus of Pulmoniferous *Mollusca*, embracing the various forms of animals called Snails. The following are the characters of this genus:—Shell spiral, opaque, or translucent, solid or thin, more or less globose, in some discoid, smooth or sculptured; surface variously coloured, but seldom covered with a polished epidermis; mouth lunated, thickened within, simple or toothed; peristome frequently reflexed. Animal moderately large in proportion to shell: head with four developed tentacles; mantle not reflected on shell; tail lanceolate and never truncate; foot often ample; tongue with the edge teeth serrate. (Forbes and Hanley.) The species of this genus, at the approach of winter, or in very dry weather in summer, recede into their shell, and secrete a quantity of mucus, which forms a covering over the aperture. This thickened matter, which the animal has the power of throwing off by producing fresh mucus within, is called an 'epiphragm.'

(4287) HEMEROCALLIS, a genus of Plants belonging to the natural order *Liliaceæ*. It has a campanulate corolla, seated on a cylindrical tube; the stamens are bent down; the capsule is 3-edged; the root is composed of thick fibres; the leaves are scattered, linear; the flowers are large, yellow, or yellow-brown. The species are called Day-Lilies. *H. flava* is a native of Germany, and *H. fulva* of Italy. Several species are cultivated in our gardens, as *H. disticha* from China. *H. Sieboldii* from Japan, *H. speciosa*, and *H. graminea.*

(4288) HEMEROCALLIS FULVA. NARCISSUS OF INDIA.

Nurgus, Gool-nurgus, HIND.

Cultivated as a flower (Brown Day Lily.) The Narcissus fistulosus is also cultivated in European gardens.—*Gen. Med. Top. page* 189.

(4289) HEMIDESMUS INDICUS. *Syn.* Periploca Indica, *Willd.* Asclepias Pseudosarsa, *Roxb. Fl. Ind.* ii. 39.

Vern. Ununtamul, HIND. and BENG.

This is common all over the Indian peninsula. The root is long and slender, with few ramifications, covered with rust-coloured very fragrant bark, the odour remaining after drying, and strongly resembling that of new mown hay. The roots of this plant have been long employed on the Madras coast as a substitute for sarsaparilla, and have been also used in England and very highly spoken of. Dr. O'Shaughnessy's trials were numerous and satisfactory. Its diuretic operation is very remarkable; two ounces infused in a pint of water, and allowed to cool, was the quantity usually employed daily, and by such doses the discharge of urine was generally trebled or quadrupled. It also acted as a diaphoretic and tonic, and so increased the appetite that it became a most popular remedy in his hospital, the patients themselves entreating its administration and continuance. The taste and smell of the infusion are balmy and sweet; he used it with the most decided benefit in numerous cases of the description in which sarsaparilla is generally given; indeed he considers the activity of his medicine to be much more decided than that of sarsaparilla itself. The ununtamul can be purchased in Calcutta of good quality at from two to four annas the seer. No good analysis has yet been made of this drug. A volatile acid is described by Mr. Garden of London as having been obtained from

the *Smilax aspera*, under which name it is thought H. indicus became the subject of his experiments. This is however as yet doubtful.—*O'Shaughnessy, page* 456. Indian substitute for Sarsaparilla ; occurs in bundles, about a foot and a half long ; smell fragrant, enduring ; fracture white ; boiled in water, vapour very agreeable.

(4290) HEMIONITIS CORDIFOLIA. MULE FERN. In Tenasserim, near the sea shore, a species of mule fern with cordate fronds is sometimes seen.

(4291) HEMP.

The Indian plant has been generally thought to be a species entirely distinct from the European one, but Roxburgh, Royle, O'Shaughnessy, and Hamilton assume that the *Cunabis sativa* and *indica* are identical.—*Faulkner*. Cannabis (in Greek κάνναβις, and in Latin also Cannabis,) is a genus of plants belonging to the natural order Cannabinaceæ. The cannabis sativa is the only species known ; it is said to be a native of Persia, and is certainly wild, according to Roxburgh " among the hills and mountains north of India, as well as common everywhere in the gardens of the natives throughout Asia." It is now universally distributed over the north of Europe. Herodotus, iv. 74, describes it as growing in Scythia, north of the Danube, a country which he had visited. We must from this conclude that the plant is really a native of north and east Europe. If a person remains for any length of time amongst a plantation of young hemp, head-ache and vertigo are often the result, in hotter countries these effects are much more violent, a kind of intoxication being speedily produced. Oriental nations have taken advantage of this to add another to the list of intoxicating drugs, which they contrive to substitute for the forbidden wine of western people. The powdered leaves mixed with some kind of aromatic are infused in water and drunk, when a drowsy ecstatic feeling comes on, which is said to be much more agreeable than that produced by opium. The leaves are also mixed with tobacco for smoking. The two chapters of Herod., iv. 74, 75, are curious as to its intoxicating effects, &c. The drugs obtained from hemp are called bang, haschish, and cherris : gangika, ganja, kinnab, subjah, majah, are other names for it. The seeds of hemp abound in a thick mucilage, and are used medicinally for the preparation of emulsions : a useful oil is obtained from them by pressure. The hemp develops its active properties more in warm climates, hence for medicinal purposes it is brought into England from India under the name of *Cannabis indica*. —*Engl. Cyc. page* 759. We have already noticed, under the head of cannabis the scientific relations of the plant, and restrict this article to its commercial relations. In various notices of Indian fibres we frequently meet with the word *Sunn*, as indicating a particular kind of Indian fibre. Sometimes we find it called *Indian Hemp*, and we may often see *Hemp* enumerated as one of the exports from India. At other times we may see either the same or another fibre mentioned by the name of *Brown Hemp*. Now these various names are sometimes applied to the fibre of one or of two different plants, or are employed to distinguish the fibre of three distinct plants all of which are grown for their fibres, and have been, and might be exported from India, though only two of them are now usually to be found among the exports from that country. Hence, to avoid ambiguity, it is necessary to notice the plants to which these several names are correctly applicable.

The true Hemp (*Cannabis sativa*) the subject of the present article is everywhere cultivated by the natives in the plains of India, not on account of its fibres, but for its intoxicating leaves and their secretions. In the Himalayas, however, the fibre is separated for economic purposes, and was exported from India to England during the last war, but it has not been so for many years.

The fibre of the *Sunn* or *Taag* (*Crotalaria juncea*) is often called Indian Hemp, but incorrectly. It is the kind most generally cultivated all over India on account of its fibre, and is that usually mentioned in the exports from Calcutta under the name of Hemp, but also as Sunn. The plant may be distinguished by its flowers being of a bright yellow colour, and of the form of the Pea and of the Laburnum, while the leaves are entire and lanceolate.

The *Ambaree* (*Hibiscus cannabinus*), *Mesta paut* of Bengal, and *Palungoo* of Madras, is also very generally cultivated all over India, and exported of very good quality from the west side of that country. Its leaves are both entire and lobed, its flowers are large, and in shape resemble those of the Mallow, the Hollyhock, and the Cotton plant, of a sulphur-yellow colour with a dark brown centre. The fibre of this plant is, like that of Jute, sometimes called *paut*, and also *Indian Hemp*. It is often confounded with that of the Sunn, as it is one of the kinds of Brown Hemp of Bombay, though the two plants differ much from each other.

In the exports from the different Presidencies of India, it is very difficult to distinguish these different kinds of fibre, inasmuch as the same name, Hemp, is applied to the exports from all the three Presidencies ; but we believe, speaking generally, that the *Sunn* (*Crotalaria juncea*) is chiefly exported from all the three

Presidencies, and one kind of Brown Hemp (*Hibiscus cannabinus*), along with the other kind, *Taag*, from Bombay.—*Royle Fib. Pl. p.* 352. There has a great increase taken place in the commerce of Indian fibres and a tabular statement has been given of the exports of fibrous substances from the three Presidencies. In subsequent pages, the detailed exports of Coir and of Jute have been separately given, and *Ambaree* or *Hibiscus* fibre, has been noticed under both heads. In Britain, Jute has not hitherto been separated from the others; though it will be so in future reports. In the following table, therefore, the details of the Exports of Indian substitutes for Hemp are given, consisting chiefly of Sunn (Crotalaria); but some Hibiscus, and perhaps a little of Dhunchee, may be included.

In a late Minute, published by the Madras Government (19th September, 1854) for the express purpose of directing attention to the fibrous productions of that presidency, the exports are given as valued at the following sums, in the respective years from 1847 to 1852, excluding Coir and Coir rope. The year selected above, in consequence of the published accounts of the three Presidencies being complete, is that in which the exports were the smallest.

	Hemp.
1847-48	Rs. 19,819
1848-49	„ 23,242
1849-50	„ 23,076
1850-51	„ 10,577
1851-52	„ 46,683

Among the Imports of the three Presidencies, we find Cordage and Canvas; but excellent cordage is now made in Calcutta, both by Messrs. Thompson and by Messrs. Harton, as evidenced by the specimens which both sent to the Exhibition of 1851. Some of the canvas also is of excellent quality, as that sent from Travancore. Europe Canvas is generally preferred in India, though much dearer, that is, Rs. 24 5 6 per bolt of thirty-nine yards each, and country Canvas being only Rs. 16; because the former is so much more durable, and therefore cheaper in the end. But there is no doubt that some of the India Canvas is of much better quality than others; and it is desirable to ascertain where the best qualities are made, as well as of Twine and of Cordage; for though much depends upon manufacture, something is due to the fibre, and not a little to the soil and climate where the plant is grown. Bombay, from its insular situation, requires both its Imports (some by sea, others by causeway) and Exports to be noticed. Among the Imports we find Canvas, 9367 bolts, from the United Kingdom, Calcutta, Malabar, and Canara; Gunny bags, 2,729,407, from Calcutta, Malabar, Canara, and Concan. The first are no doubt made of Jute; but the others, probably, of Sunn. Hemp, 57,126 cwt. from Malabar and Canara, Concan, Guzerat, Goa, and the Arabian and Persian Gulfs. This probably includes both *Sunn* and *Ambaree*, or Crotalaria and Hibiscus fibre. Twine, 9738 cwt. from the United Kingdom, Calcutta, and Guzerat; Fishing Nets from the Concan, probably made of Conkanee Hemp; and Grass cloth from China. Of these, we find among the Re-exports, some Hemp, Canvas, Gunnies, and Twine, as well as China-grass cloth.—*Royle Fib. Pl. page* 298.

We now proceed to our notice of the true Hemp.

Bhanga, Ganjica, Sans.	Kinnub, Arab.
Ganja, Hind.	Bung, Pers.

Though, as we have seen, many fibres are known in commerce under the name of Hemp, the true Hemp plant is the *Cannabis sativa* of botanists. Its fibre is so generally employed for cordage in Europe, that the value of all other fibres is estimated there, not so much

from their intrinsic properties, as from their greater or less resemblance to Hemp, and especially to Russian Hemp. There is every reason for believing that the plant is of Eastern origin, while there is no sufficient reason for thinking that the climate of Europe is so peculiarly suited to the production of its fibre, as to exclude those of its native climes. Especially where attention is paid to the places where the plant is grown on account of its fibre, and these distinguished from the others where it is cultivated for its resinous and intoxicating secretion. For the latter purpose the plant requires exposure to light and air and these are obtained by thin sowing, while the growth of fibre is promoted by shade and moisture, which are procured by thick sowing. By the celebrated Jussieu, the Hemp and the Hop plants were placed in the same natural family (*Urticeæ*) with the Nettles. In more modern works, they are either continued as a tribe of the same family, under the name of *Cannabineæ*, or these containing only the genera *Cannabis* and *Lupulus* are separated into a distinct family, under the same or a nearly similar name. These two plants are closely connected in properties, as in structure. The Hop (*Humulus lupulus*), besides a bitter, secretes a resinous principle: Hop bines abounding in fibre, have often been proposed to be turned to useful account, for cordage or paper, but as yet to little extent. The Hemp plant likewise secretes a resinous principle in its leaves, on which account these, as well as the *churrus* collected from off the young tops of the stem and flowers, is highly esteemed in all Eastern countries, on account of its exhilarating and intoxicating properties. Among the Arabs the Hemp has a variety of names, as "the increaser of pleasure," the cementer of friendship," &c. By its name of *Hasheesh* it is often mentioned in the works of travellers in Egypt, Arabia, and Syria; while the name of *Bhang* is not less celebrated in the far East. The Hemp is a dicœcious (occasionally moncœcious) annual, from 3 to 10 feet high, according to soil and climate. Root white, fusiform, furnished with fibres. The stem erect; when crowded, simple; but when growing apart, branched even from the bottom, angular, and, like the whole plant, covered with fine but rough pubescence. This stem is hollow within, or only filled with a soft pith. This pith is surrounded by a tender, brittle substance, consisting chiefly of cellular texture, with some woody fibres, which is called the *reed*, *boon*, and *shove* of the Hemp. Over this we have thin bark, composed of fibres, extending in a parallel direction all along the stalk. These fibres consist of delicate fibrils, united together by cellular tissue, and all covered by the thin membrane or cuticle. The leaves are opposite or alternate, on long petioles, scabrous, digitate, composed of from 5 to 7 narrow, lanceolate, sharply serrated leaflets, of which the lower are the smallest, all tapering at the apex into a long entire point. Stipules subulate. *Males* on a separate plant. Flowers in drooping, axillary, or racemose panicles, with subulate bracts. Perianth 5-parted; segments not quite equal, downy. Stamens 5; filaments short; anthers large, pendulous, 2-celled; cells united by their backs, opening by a longitudinal slit. *Females* in a crowded spike-like raceme, with leafy bracts. The perianth consists of a single, small, spathe-like sepal, which is persistent, acuminate, ventricose at the base, embraces the ovary, and is covered with short brownish glands. Ovary subglobular, 1-celled, with one pendulous ovule. Style short. Stigmas 2, elongated, glandular. Nut ovate, greyish-coloured, smooth, covered by the calycine sepal, bivalved but not dehiscing, and inclosing a single oily seed. Seed pendulous. Testa thin, membranous, marred at the apex with a coloured hilum. Embryo without albumen, doubled upon itself. Radicle elongated, turned towards the hilum, and the apex of the nut separated from the incumbent plano-convex cotyledons by a small quantity of albumen. The cultivation of Hemp in India obtained very great attention from the Court of Directors, and instructions were sent to the Governments there to encourage its growth, as well as that of other cordage plants. As the natives of India employ between forty and fifty different kinds of plants for the fibre which they yield, fitted for this purpose in different degrees, the subject of investigation was sufficiently extensive, and received great attention from Dr. Roxburgh. It is in general supposed that it can only be successfully cultivated in European regions, though there is every reason to believe thst it is originally a native of Asia, and even that its Greek and Latin name *Cannabis* is derived from the Arabic *kinnub*. It is well known to be common in Arabia and Persia, as well as in every part of China and of India, and likewise in Egypt and Turkey; but in all these countries it is valued chiefly, if not only, for yielding an intoxicating drug commonly called *bhang*. In European countries, it is on the contrary cultivated only on account of its ligneous fibre, so extensively employed in the manufacture of the strongest ropes, and of coarse but strong kinds of cloth. Hemp is cultivated in almost every part of Europe for home consumption, but only in large quantities for export in Russia and Poland, though the finest quality of Hemp comes from Italy. French Hemp is also much esteemed, as well as that grown in both England and Ireland; Hemp is cultivated in almost every province of Russia, but in the largest quantities in the interior, beyond Moscow, as well as nearer Petersburgh, and in the Polish provinces which belong to Russia. The soil must not be over rich nor too sterile, of moderate depth, and friable. The time of sowing varies from the middle of May

to the end of June; by some it is recommended not to be sown until the latter end of June, as frosts are very injurious to its growth. The season of reaping is from the end of August to the end of September, and it is therefore between three and four months in a state of vegetation; the male plants being pulled some weeks before the female. The Russian summer though short, is regular while it lasts, and the temperature sufficiently high to bring it to full perfection. That the northern latitudes of Russia are not essential for the successful cultivation of Hemp, is, however, evident, from large quantities which are grown in the southern climate of Italy, both in Bologna and Romagna, and along the banks of the Po, as well as in the neighbourhood of Naples. The Italians have a saying, that 'Hemp may be grown everywhere, but it cannot be produced fit for use, either in heaven or earth, without manure.' The climate of Italy, it is well known, is remarkable for its clearness, regularity, dryness, and warmth, and that irrigation is essentially necessary for much of its agriculture. The Italian Hemp is fine, soft, light-coloured, and strong, as well as long in the staple, and it is important to remark that it brings the highest price in the English market as, for instance, it sells for 50 shillings per cwt. when the best Russian sells at 47 shillings for the same quantity. If we compare the summer temperature of the northern with these southern situations, we shall not find so great a difference as we might be led to expect by considering only their latitudes, or their mean annual temperatures. Thus Petersburgh and Moscow, in N. latitude 59° 56 and 56° 45, have mean summer temperatures of 62° 09 and 67° 10, of Fahr., while Milan and Rome, in N. latitude 45° 28 and 41° 53, have summer temperatures of 73° 04 and 75° 20. "Without entering into details, it might be inferred as probable, that as Italy grows Rice, and so many other plants of India, so might the latter cultivate a plant like the Hemp, which succeeds so well even so far south as Naples, and which requires only a few months to bring it to perfection; and this even if India did not already possess it. But so far from this being the case, the reverse is the fact; and it is well known that no plant is so commonly cultivated in so many parts of India as the true Hemp plant, which is there called *ganja*, but which differs in no respect from the European plant, though the natives employ it only for the purpose of yielding *bhang*. But cultivated for this purpose, instead of being sown thick, as it ought to be when intended for cordage, it is sown thin by the natives, who afterwards transplant the young plants, and place them at distances of nine or ten feet from each other. The effect of this is to expose them more freely to light, heat, and air, by the agency of which the plant is enabled to perfect its secretions in a more complete manner, and the bhang will consequently be of a more intoxicating nature. The fibrous and woody parts at the same time attain a greater degree of stiffness and solidity, as is found to be the case with timber trees similarly exposed. The Hemp plant, thus grown, will branch much. It may be small in dry situations, and large in rich and moist ones, but in either case its fibres are found, both in Europe and India, to be rougher, stiffer, and more difficultly separated from the woody part than is desirable, but seed is produced in larger quantity and of better quality. This mode of cultivation has, moreover, the disadvantage of being more expensive, from taking up more space than is desirable when the plants are required to yield the best quality of fibre for cordage. Plants, when grown in moist situations, in shade, or set thickly together, are well known to run into leaf, shoot up, and to become more lax in texture, while their secretions are imperfectly formed, as is exemplified in the growing of Lettuce, Celery, &c. Hemp and Flax, when cultivated for their fibres, are sown thickly together, and they shoot up into long, wand-like plants, which are much less branched than when freely exposed. Air and light having less free admission, and heat having less influence in evaporating the sap, the effect is to produce a longer fibre, which is at the same time soft and pliable, as well as more easily separated, and in larger quantity on the same space, than when they are set widely apart. "The natives of India also sow their *Sunn* and *Jute* very thickly together when, for the sake of their fibres, they form the exclusive crop. The effect is to produce a long and flexible fibre, though this is not sufficiently strong to form a good substitute for the true Hemp. This might be cultivated in suitable situations in India, in a manner similar to that adopted in Europe, or like that practised with its substitutes in India. The effect would undoubtedly be to produce a sufficiently long fibre, which would also be softer and more pliable, at the same time that it retained a great portion of its original strength, and probably in as large a quantity as is yielded by the *Sunn* plant. Thus an article might be produced, which, judging from the Italian samples, might enter into competition with the Russian product, and, at all events, afford much more valuable cordage than the several (usually considered) inefficient substitutes which are so extensively cultivated in India, and which, imported into this country, sell only for 15 to 20 shillings per cwt., at the same time that the Russian, Polish, and Italian Hemps are selling for 42 to 50 shillings per cwt. "The difference in price would appear a sufficient inducement to attempt the culture of the true Hemp in India, especially as there could be no doubt respecting its growth, as it is already so common in every part of that country,

d requiring, if anything, only a little modifi-
tion of its properties. This could be ensured,
ost probably, by a change in the mode of culti-
tion. Dr. Roxburgh, as long since as the year
00, thought Rohilcund and the neighbouring
lls suited to the cultivation of Hemp. Dr. Royle
s seen it in great abundance, in a wild state, in
e Deyra Doon, and also in the Khadir land of
eSaharunpore district, especially along the upper
rt of the Doab Canal, and where it was chiefly
lued for its leaves, being made into *bhang* and
hjee, and the stems, when dried up, being
rnt for firewood. "There would be little diffi-
lty in cultivating this plant in the low *Khadir*
id, where it is wild; nor in converting it into
erchantable Hemp. For the natives of the
ighbourhood already make use of it partially
r the manufacture of ropes; and the inhabitants
Malabar are said by Dr. H. Scott to employ
e Hemp for making their fishing nets. The
tives of the Himalayas likewise possess the
ant, from which though they prepare an
toxicating drug, which they call *churrus*,
ey likewise value it for its ligneous fibre,
om which they prepare a coarse kind of
oth, which they send into the plains for
aking very durable *grain-sacks*, as well as the
rongest ropes (called *sel*), for crossing their
vers This fact, though not generally known, is
entioned by Kirkpatrick in his account of Nepal,
id was ascertained by General Hardwick, in his
sit to Srinuggur, as well as by Dr. Royle, when
avelling in the Himalayas ('Illust.,' p. 333).
e also obtained specimens of the rope and cloth
hen travelling there. The plant he saw in a
ry luxuriant state at least ten or twelve feet high,
the Himalayas, at elevations of 6000 and 7000
et, especially in the neighbourhood of buffalo-
eds. In such situations and near villages it
ould no doubt be easily cultivated to a great
xtent, and yield a valuable and profitable pro-
uct. "The Hemp could likewise be cultivated
the plains at two seasons of the year; that is,
aring the rainy season, as is now the case, but
kewise along with the cold-weather cultivation,
hich is so similar to that of the summer culture
European countries. But experiments require
be made and specimens procured in order to
etermine which season is most proper for
e culture of this plant in order to yield
emp of the best quality. "Hill people
ight no doubt easily be obtained for preparing
e Hemp according to their own method, and
aching the people in the plains, who are already
actised in the art of preparing *Sunn*. It would,
owever, be desirable to procure, if practicable,
e assistance of some European (and such might
e found among the soldiery) who had seen and
actised the preparation of Hemp in this coun-
y. The several papers sent to the Agri-Horti-
ltural Society of Calcutta, were published in
ol. viii. of their 'Transactions,' and in vol. i. of

their 'Journal.' These were from Majors Swet-
enham and Corbett, Captains Kirke and Huddle-
ston, and from the distinguished naturalist, Mr.
Hodgson. The substance of the last two we
here republish, as containing much of the inform-
ation on culture contained in the others, while
Major Corbett and Capt. Kirke give valuable in-
formation respecting the cost and the expense of
conveyance to Calcutta; which will be immedi-
ately noticed.

Extracts from a Report on Hemp Cultivation, &c., in British Gurhwal, by Captain H. Huddleston, 14th July, 1840.—There are two kinds of Hemp, "*Bhang*" indigenous to the Himalayas; —that called "Khur-Bhunga," or Jungle Bhang, growing wild throughout the whole of these Hills in all situations, and attaining a very considerable height during the season of the periodical rains, is of no use whatever, for the very insignificant quantity of "churrus" (the inspissated juice of the leaves obtained from the plant by rubbing between the hands) does not remunerate even the poorest class for the trouble bestowed upon it, and as it does not yield a fibre that can be turned to any use, I need not of course make any further remarks regarding it. The real Hemp, or cultivated kind, is grown chiefly on high lands, and principally on the northern faces of the mountains, in well prepared and abundantly manured soils close to villages, or in recently cleared lands by burning the primeval forests, the soil of which from the accumulated decomposed vegetable matter of years, is rich enough to ensure the superior growth of the plant and an abundant crop without any manure for one season. No irrigation is ever resorted to, and very little is produced under an elevation of 3000 feet, the heat of the valleys being detrimental to its quality, and the plant appears to flourish best at elevations of from between 4000 to 7000 feet. The middling district situated between the "Pindur" to the north and the "Nyar" or "Samee" rivers to the south, and centrically with regard to the province of Kumaon and Gurhwal may be termed the chief Hemp-producing districts of British Gurhwal. The fields nearest to villages, as being the easiest for manuring, and the culturable wastes with a rich soil of accumulated, rotten vegetation, or recently cleared forest lands, being those in which the Hemp plant is alone cultivated to advantage with respect to its quality. The culture of "Bhang" or Hemp, as practised in this district, is as follows: After the ground has been well cleared and prepared, the seed is sown, towards the end of May, or early in June, at the rate of 20 or 25 *pathas*, equal to about 26 or 33 seers (from 52lb. to 66 lb. avoirdupois) per beesee, which latter is the common denomination now used in Gurhwal, and very near equal to an English acre. During the early growth of the plant the ground is kept free from all weeds, and

the young plants are thinned, leaving a few inches, between each, and until the crop has attained a good height, the ground is kept clean from all rank vegetation—after which it attains to the height of twelve and fourteen feet, and is cut in September and November. Of this cultivated Bhang there are two kinds, the plant called *Goolanya* or *Goolbhanga* which produces seed (the female), and the one which only flowers, but has no seed; and this latter is called "Phoolbhang" (the male), from which the best sort of Hemp is prepared; the plants being cut a month or six weeks earlier, and producing a stronger and superior fibre to the other. On the stalks being cut green, they are dried for several days in the sun, by being piled against the walls of the terraced fields until they become quite brown. The plants have the seed extracted by rubbing between the hands, which produces the "Churrus," and this is scraped off and made into rolls for sale. The leaves also are pounded, from which "Ganjah" and "Subzee" are manufactured in small quantities. When the stalks are sufficiently dry they are tied up into bundles, and steeped for fifteen or sixteen days (eight days, Swetenham) in tanks or running streams, being kept under water by pressure—on being taken out they are beaten with wooden mallets, and dried again in the sun, when the fibre is stripped off from the thickest end of the stalk, and after being again beaten, this fibre is made up into twists for sale and manufactured into sackcloth for wear, bags, and ropes. The total money return from the produce of the cultivation of the Hemp plant would be considerable, if there were any demand for exportation, though the average return even now is amply remunerating to the grower, and were it not from the well-known dislike which the Hill people have to extra labour, it would be more extensively cultivated than it is. The limited cultivation at present, however, supplies the wants of the population for sackcloth, bags, and ropes, nearly the whole of which, in considerable quantities, is consumed in the district—the lower classes of the Gurhwal population dressing themselves in the cloth manufactured from the Hemp, and this still encourages the cultivation in a great measure. The average return per beesee (or English acre) may be stated as follows:—three seers (6 lb.) of churrus, value Rs. 6 (or twelve shillings); four maunds (or 320 lb.) of Hemp, value Rs. 8 (sixteen shillings); and about thirty to thirty-five seers (60 to 70 lb.) of seed, yielding about five seers (10 lb.) of oil, value R. 1 (two shillings). Giving a total of Rs. 15 per beesee. The seed sells generally at 20 *puthas* per rupee, or from twenty-seven to thirty seers (as this wooden measure varies in different places) and the seed being light, I have found that the average weight of each patha is about one seer and five chittacks. The Hemp sells at 2 rupees a maund amongst themselves, and the Dooms (or lowest class of the agricultural community) are the chief cultivators of the plant. When Dr. Rutherford held a contract for the supply of Hemp to the Honorable Company, and also made extensive purchases of it with other staple articles of produce of the Hills on his own account, the cultivation of Hemp was very considerable indeed in this district; and in case of any demand being again created, immense tracts would no doubt be sown with it, provided the same plan of advances to cultivators were adopted. The plan adopted by Dr. Rutherford appears to have been thus: advances through his agents to the landed proprietors and individual cultivators were made during the early part of the year, stipulating for the Hemp being delivered at their own doors at 4 rupees a maund, and the carriage during the cold season to the marts of Kotedwarra in Gurhwal, and Chilkeea in Kumaon at the foot of the Hills (where Goomashtas or agents were ready to receive the Hemp), being defrayed extra—which did not, I imagine, on an average exceed a rupee a maund—so that the raw material was and is capable of being delivered at those marts for 5 rupees a maund; and as only a few miles further of land carriage would be required to ship the Hemp into boats on the Ganges or Ram Gunga for transit to Calcutta, this would not, I should think, double the cost of it.

Hemp Cultivation in Nepaul, by H.B. Hodgson, Esq. Mr. Hodgson states, that the cultivation is peculiar to the Northern districts of Nepaul, but only, as he suspects, because the tribes inhabiting them are less scrupulous than the people of the great valley, and other Central and Southern tracts; for, at least in the valley, the plant flourishes greatly, if properly tended, as Mr. Hodgson has proved in his own garden; and the spring crops of the valley are almost choked with *spontaneous* growth of Hemp, which, however, being uncultivated, is stunted and virtueless. The Northern districts (popularly called Cachar) are nevertheless the prime seats of culture, and there alone is the plant manufactured into rope or cloth; though the edible extracts are sometimes prepared nearer to and around Katmandhoo. The season of sowing Bhang seed in Nepaul is from Chyett to Bysack (March to April). Damp soils, comprising black earth, are fittest for this crop. Before ploughing the field, sufficient manure is to be sprinkled over it, then completing the work of the plough, the seeds are to be sprinkled, and having broken the clods into dust, the field is to be made even. In seven or eight days after sowing the seeds, the plants came up, but their rapidity of growth and their size and strength depend on the abundance of the rains or artificial watering. If the plants be very thick, they must be thinned, so as to stand

three inches distance from each other. They flower and fruit in Sawun (July); and at the beginning of Bhadoon (August) are in their full growth; but while yet succulent and in flower, they are to be cut, with the exception of some seed plants, which are not to be reaped till October. It is the bark of the young but full-grown or Sawun plants, which is soft, that is used for making Bhangela. That of the old or October plants is hard and not suitable for manufacture. After the plants have been cut off at the ground, they must be placed in the sun for eight or ten days or until they be dried sufficiently. They must then be steeped in water for three days, and on the fourth day the plants must be taken out of the water and peeled. The peelings are to be washed and put in the sun; and when quite dried, they are ready for manipulation. They are then to be torn into thin threads with the nails of the hands; next twisted with a spinning-wheel (Tikuli) and when the threads are thus prepared, they are to be boiled with ashes of wood and water in a pot, for four hours, and to be washed again for the purpose of whitening. This is the way of preparing Bhangela thread, out of which blankets are woven. One *mana* (half a kutcha seer) of seed is sufficient for a ropini of land (one fifth of Badshahi bigah), which produces ten or twelve loads of bhang. Hemp grows equally well on slopes or flats, and near the tops as well as on the sides of the mountains, if not too low. But a moist rich soil is indispensable. The plant attains to a height of eight to ten feet, and should be cut when the flower is falling and the seed forming.

Hemp Culture in the Plains of India.—Though the production of Hemp in the Himalayas, and in the low lands at their foot, is chiefly contemplated, that of its culture in the plains may also be mentioned. This was attempted by Dr. Roxburgh, and though probably in the least favorable situation in India, yet with some success; as he observes: "In many parts of Bengal, particularly where the land is so low as to remain humid through the dry season, Hemp thrives luxuriantly during the cold season; at Soonamooky it did well on a sandy soil, manured with dung from stables. Prolonged immersion much injures the quality of the Hemp, the rainy season is therefore preferable for the cultivation and maceration of the plant, and we must content ourselves with one crop in the year, for it is a very false, though prevailing notion, that the fertile fields of Asia produce at least two crops annually. The burning heats of Asia, while they last, are as unfavorable for vegetation as the frosts of winter are in Europe." And in Wisset it is stated: "A native, who had an opportunity of observing the mode of cultivating and preparing the Hemp raised by Mr. Douglas, at Rishera, has offered to the Board of Trade to contract with them for supplying a very considerable quantity, I believe 500 maunds (about 17 tons), of properly dressed Hemp next season, at the rate of ten sicca rupees per maund (this is equal to 300 sicca rupees, or, at 2*s.* 6*d.* = £35 per ton, and at 2*s.* = £30 per ton). The next important notice which we have respecting the culture of Hemp in the plains of India, is from Mr. Deneef, and of and from whom we have the following communication: Sample of Hemp grown and manufactured in Bengal, after the manner pursued in Belgium. Presented by Mr. H. Woollaston, on behalf of Mr. G. Deneef, Belgian farmer. Monsieur Spry, Secretaire de la Societe d'Agriculture et d'Horticulture du Bengale, Calcutta, Oc. 8, 7630, 1840. J'ai l'honneur de vous envoyer par l'entremise de Monsieur Woollaston, membre de votre Societe, un echantillon de chanvre, qui me semble meriter beaucoup d'attention, il me parait aussi avantageux qui le chanvre de Russie et de Manille qui se vendent a Londres £22 a £27 le tonneau. La manufacture en est tres simple et n'exige pas aucun instrument, elle est faite en Belgique par des vieillards et des enfants. Aucun ouvrage ne saurait etre plus convenable pour les bras inactifs des familles pauvres de cette contree, il n'est nullement fatigant et se fait par assis; de plus, chaque livre de chanvre, procure au teilleur 3 lb. de matiere a bruler. La preparation du sol ne demande pas de grands soins ni par consequent de grandes depenses; sa vegetation est superbe, la plante n'occupe le sol que pendant 80 jours (du commencement de Juin, a la fin d' Aout). J'en ai a peu pres 4 beegas, qui me donneront environ 1000 lb. de fibres, que je prepare en ce moment; et que je me propose d'envoyer le plutot possible, pour echantillon, a la Societe experimentale du Lin a Londres, et apres en avoir recu une reponse, concernant sa valeur reelle; je m'empresserai de vous envoyer un rapport exact sur la mode de sa culture. Il serait etonnant que l'Inde, qui a tant de moyens en terrain et en hommes, ne pourrait pas concourir avec la Russie, qui est obligee de payer £2 0 0 par tonneau frais d'exportation au gouvernement Russe meme, et 6*s.* per tonneau au passage qu Sond, et ne pourrait reclamer sa part, des millions d'especes, que la mere patrie est obligee de payer annuellement a la Russie sa puissante rivale. J'ai l'honneur de vous saluer avec la plus parfaite consideration, Votre tres devoue serviteur, G. Deneef, Belgian Farmer. The Hemp produced by so little labour and care, and which only occupied the ground for eighty days from the beginning of June to the end of August, according to Mr. Deneef, was pronounced good by the members of the Flax and Hemp Committee; by Mr. Fergusson, as "uncommonly strong, and if it can be produced cheaply and abundantly, it is likely to be a most important article." Mr. Hodgkinson, who doubted of its being the true Hemp—though without sufficient grounds,

pronounced "the article as superior, be it what it may, and deserving of the first attention." With respect to the interchange of seed, or to the kind which is most desirable, we have the following fact, though it is probable that some of the Himalayan seed would answer equally well. A few fresh stalks of Hemp raised from Russian seed were received from Dr. Royle, and corresponding specimens of the indigenous Hemp plant of Bengal. *Presented by Mr. Deneef.* The superiority of the former in texture was very apparent." In treating of both Flax and Sunn, mention was made of Mr. Sconce's experiments with both of these plants at Chittagong, in the year 1843. He at the same time grew some Hemp from country seed (*gonza*) sown in November. Of the fibre, the Hemp and Flax Committee reported: The Fibre is exceedingly strong and clean, but the admixture of Tow spoils the appearance and deteriorates the quality; while of the dressed Hemp it was said, that some of fibres were strong, others weak, and as only partially heckled. These defects, being those of management, might easily be remedied. From the far Southern we proceed to the North-Western provinces; here the late Mr. Bell, of Agra, on hearing of the above experiments in Bengal, writes, that there "can be no difficulty in the cultivation of the *bhang* or *ganja*, which is now sown only for the intoxicating drug the natives obtain from it; but the vigour the plant shows, and the height it reaches when thus sown, much scattered to admit of its throwing out its branches, satisfied me that, sown more densely, it would at least run the height of Sunn, and this I suppose sufficient for the desired length of fibre in the Hemp." There is no doubt that the Hemp plant will grow to a great height even in the plains of India. Dr. Royle received a letter from his friend, Capt., now Sir Proby Cautley, dated from Saharunpore (10th Aug., 1840), stating that the Hemp was in cultivation in the Botanic Garden, and looking as fine as any that he had ever seen, nearly twelve feet high, with a natural healthy look of dark green. Dr. Falconer, however, afterwards reported that the Hemp fibre did not retain the strength or flexibility which characterise it in the Himalayas. But Dr. Royle has been informed that they are able to use some of the Hemp growing spontaneously along the part of the Himalayan base, for the general purposes of cordage. The Hemp growing in the Goruckpore district at the foot of the Hills, is considered of good quality, and some was sent to Britain on purpose to have its properties tested. It is probable that Mr. Williams might succeed in the cultivation of Hemp in the soil and climate of Jubbulpore.

Quality and Cost of Himalayan Hemp.—From the account which has been given above, by local officers, of the cultivation, and the other testimony which we have respecting the plant, there is no doubt that the Ganja of the Himalayas is the true Hemp plant of Europe (the *Cannabis sativa* of botanists). As the plant has ceased to be as extensively cultivated as formerly chiefly from the want of any external demand, there would seem to be no difficulty in again increasing the culture, and to a still greater extent, if this requisite for all culture was again restored. The only questions which remain to be determined are the quality of the Hemp and the cost at which it could be conveyed to Indian ports, where, if not required for export to Europe, it could be beneficially employed for naval and other purposes. This would be preferable to their continuing, as in some places is still the case, to import Hemp and Tow from Europe, when India produces at least as good, if not a superior article, and at a cheaper rate. This is evident from the following abstract of the information on the subject. "In the Himalayas the Hemp grows wild, and is, moreover, carefully cultivated, both on account of its exhilarating secretions, and its strong and flexible fibre. With the properties of this the Hillmen are well acquainted, as they make with it both twine and rope, and a coarse cloth (*bhangela*) with which they clothe themselves, as well as make sacks and bags. Their hempen wrappers they wear much as a Highlander does his plaid, fixing it in front with a wooden skewer, instead of a brooch. A traveller in the Himalayas, some years since, described the natives as applying Hemp 'extensively to purposes of a domestic nature, such as hanging their supernumerary female children, administering rope's end to their wives, penning up cattle, and making a sort of netted, or knitted, or knotted shoes, to which a sole of untanned leather is sometimes, but by no means generally, affixed.' "The culture seems to be very well understood in most parts, though the best methods are not always practised either of planting, or of picking, or of preparing their Hemp. All along the Himalayas—that is in Nepaul, in Kumaon, in Gurhwal, and up to the newly acquired hills of the Punjaub, at elevations of from 3000 and 4000 to 7000 feet —Hemp is cultivated by the Hillmen, though chiefly for their own use, the plants growing to eight or ten, some say twelve or fourteen, feet in height. They sow about the month of May, carefully prepare, and usually manure the ground, weed and thin the plants to within three or four inches, and cut the male plants, '*phoolbhanga*, which flowers, but has no seed,' a month or six weeks before the female plant, '*goolanga*, or *goolbhanga*, which has seed,' the latter being harvested about the end of September. The stems, when cut down, are dried in the sun, and then steeped in water for three or more days. Beaten with wooden mallets, the fibre is then stripped off, and again beaten. In some places it is said to be boiled with wood ashes—that is,

potash,—and sometimes bleached before being spun into thread. The stalks are made into torches. The culture is described to be the most profitable of any, as the *churrus* and *ganja*, different forms of *bhang*, are said of themselves to pay the expenses of culture. The Hemp they sell among themselves for Rs. 2 a maund—that is, 4s. for about 82lb. The seed is even roasted and eaten, or expressed for its oil, and the oil-cake given to their cattle. The culture is not much extended, for it is more laborious than they like, and there is said to be a prejudice among the Brahmins and Rajpoots against the cultivation of this plant, which is therefore confined to the Doom class. But there is no doubt that the culture could be immensely extended if the inducements of price were greater." There being no doubt of this being the genuine Hemp plant, the next point to ascertain is the quality of the fibre which the natives produce with their own unaided efforts. On this point the information is most satisfactory. Mr. Hodgkinson, a Calcutta merchant, who was well acquainted with this staple, and had personal knowledge of the produce on the Continent, pronounced some Hemp sent from the Deyra Doon to be "equal in colour, cleanness, length, and strength to the best Russian. Mr. Deneef, a Belgian farmer, sent to India by the Flax Experiment Company, said: "Ces echantillons sont de vrai *Cannabis sativa*, pareil a celui du nord de l'Europe. J'ai ete enchante de voir une si charmante vegetation de cette plante produite dans l'Inde; mais cet article n'est pas preparé comme on le desire dans les marches Anglais; d'abord chanvre male et chanvre femelle ont ete coupes ensemble, et ensuite dresses dans l'etat humide d'apres la methode des Indiens. S'il etait dresse a la maniere des Europeens du nord, qui consiste a tirer le chanvre male, cinq semaines avant celui qui produit la semence, a ne rouir que bien peu chaque genre separement, la chanvre male ne pouvant pas sejourner dans l'eau aussi longtemps que l'autre; ensuite a ne le dresser que quand il est bien sec et lorsque les fibres se separent aisement; il formerat une belle matiere premiere pour les cordages solides. Au contraire, dresse et rince dans l'eau il perd'une certaine graisse qui lui est naturelle, et qui est cause que la poix s'imbibe plus facilement avec lui, ce qui le rend fort contre la pluie et la chaleur, et fait en meme temps benefice du manufacturier, qui sait si bien distinguer la difference de la preparation." [In preparing Hemp for the European market, care should be taken not to twist or tie the ends together, but having laid the fibres parallel to each other, simply to tie them together near the thicker end, so as to form *heads*, as seen in Peterburgh Hemp.] ('Journ. Agric. Soc. of India,' *i*, p. 46.) Some specimens of Hemp from the Himalayas recently tried in this country have been found to bear a greater weight and strain than the best Petersburgh Hemp. Some of it is also very fine and soft, more like Flax than Hemp. There is little doubt, therefore, of the good quality of this Hemp, even without any improvement from European instruction. It is a not less important point to ascertain the price at which it could be brought to this country. In the 'Journal of the Agri-Horticultural Society of India, (vol i, p. 45), may be observed a memorandum by the late Lord Auckland, when Governor-General of India, in which it is stated:

Prime cost of Hemp at Deyra, Rs. 54 per ton, ...	£5	8	0
Carriage to Calcutta (about 1000 miles) Rs. 25 per ton, ...	2	8	0
Total cost and charges of Hemp at Calcutta, ...	£7	16	0
Prime cost of Hemp seed at Deyra Rs. 36 per ton, ...	3	12	0
Carriage to Calcutta, Rs. 24 per ton,	2	8	0
	£6	0	0

Though the above are deduced from the rates at which the natives sell Hemp and Hemp seed among themselves, large quantities could not be obtained at the above prices, for the natives would not extend their crop, or take much trouble in preparing it for market, unless some greater inducements were held out to them. Others, therefore, have calculated that the price of the Hemp might be doubled to the natives, and that one rupee more should be given for their bringing it down to the foot of the hills, whence it could be readily conveyed to the Ganges, either from Kemaon or Gurhwal, or from Sirmore it the Jumna, and from the Kangra Hills to the Sutlej. Therefore Capt. Kirke calculated the cost of 500 maunds of Hemp from Deyra Doon, a valley within the Himalaya, to be about Rs. 2500; carriage on bullocks to the Ganges (but carts have been much introduced since then), Rs. 125; a 600 maund boat from Sookertal, Rs. 130; together Rs. 2755; this, with the addition of ten per cent for contingencies, making the total cost to Calcutta. Rs. 3080 for 500 maunds of Hemp, or for something more than seventeen tons, or about £17 14*s* a ton in Calcutta. Capt. Kirke's memorandum further states that 22½ feet of the fine sailcloth which he forwarded could be bought for 9½ annas; 88½ feet of the coarse sackcloth for six annas; 20 seeds of the rough Hemp for one rupee; and 20 seeds of the Hemp seed for one rupee. Major Corbett gives three calculations of the cost of Hemp from

the district of Kemaon to Calcutta, all expenses included:

From Kotedwarra, 37 tons, £661-	£17	17	per ton.
„ Chilkeea	13	15	„
„ Sunea	13	4	„

He also sent some Hemp cloth or canvas made in the Hills, which was 7¼ yards long, and 22½ inches wide, of which the price was one rupee. The above facts being sufficiently favorable, both respecting the quality and the cost of the Himalayan Hemp, and Dr. Royle having been informed by good practical judges that the best plan to make the peculiar qualities of any of these Indian fibres known to manufacturers here would be to have a few tons of each sent into the market for two or three years, he was induced to recommend that this should be done with the Himalayan Hemp. "As it is quite practicable to give an impulse to the growth of Hemp in the Himalayas, and as the price is so moderate and the quality so good, I believe it might be established as a regular article of export from India, or, at all events, of consumption in the dockyards of that country. I would therefore suggest that the local officers of the districts of Kemaon, Deyra Doon, Sirmore, and Kote Kangra (more properly Kooloo), should be authorised to purchase certain quantities of the Hemp (say from 5 to 10 tons), and send it down to Calcutta, for transmission to and sale in the markets of England, taking care that while they give sufficient encouragement to the cultivators, they do not so far increase the cost, either by raising the price or by enhancing the expense, as to interfere with its subsequent profitable sale by merchants. It is probable that the Himalayan Hemp would sell in England for £35 a ton." Dr. Royle has lately received a letter from Dr. Jameson, dated 6th Nov., 1854, referring to this fibre, and also to the order which had been sent by the Court of Directors to India for the purchase of some of this Himalayan Hemp, in order to make it known in the markets here. He states that the Civil Authorities had "issued orders to purchase ten tons of the Hemp grown in Gurhwal and Kemaon, which they were procuring at the rate of from Rs. 4 to Rs. 6 per maund, or £10 16*s.* to £16 4*s.* per ton. Carriage to Calcutta will cost about £5, and to England, with the other incidental charges, say £10 per ton [Mr. Henley (*v.* p. 86) estimates all such charges at £7 a ton] more, which will bring the article up to £25 16*s.* to £31 4*s.* Of course, when it is exported on a larger scale the price of carriage will be greatly decreased." "This country possesses immense advantage in abundance of land, &c., and the Calcutta and Bombay merchants could always have their Hemp to ship in December." With regard to the quality of the Hemp he observes: "Moreover, the Hemp grown in our mountains and in the Doons (valleys) is far superior in strength to the Russian samples of Russian Hemp which have been sent by the Court of Directors. On showing these to the Puharee (Hill) growers of Hemp, they declared that were they to produce such an inferior article it would scarcely find a sale." The specimens were obtained from one of the most respectable houses in London, and bought for their own use. They were sent for the purpose of showing how the Hemp of commerce comes into market, instead of being twisted, tied, or platted, as is much of the fibre from India. But if the Himalayan Hemp generally resembles that which has been referred to as from Kangra, no Russian Hemp will come near it in point of strength. The essentially good qualities of the Hemp grown in the Himalayas, consisting in the strength, divisibility, fineness, and softness of the fibres of much of what is grown there, will make it, when known, very desirable for many purposes. That grown at the lower elevations is also possessed of considerable strength, as proved from the experiments made on a 2-inch rope in the Master-Attendant's office at Calcutta. The results given in the accompanying table (p. 332) are a portion of an extensive series of experiments, undertaken in the year 1840, in compliance with the orders of the Marine Board, dated 7th October, 1839. The samples of Deyra and Arracan Hemp were forwarded for experiment from the Agri-Horticultural Society, and were laid up in a 2-inch rope, in November 1841, but the experiments were interrupted by the death of the Master-Attendant, and these samples were not submitted for trial till the 18th of December, 1844, so that the rope was three years old. At the same time, the small samples of *jetee* (*v.* p. 304) were tried. It will be seen from the abstract, that amongst the thirteen samples of the 2-inch rope, the Deyrah Hemp stands the fifth in strength and the twelfth in elasticity. ('Journ. Agri-Hortic. Soc.,' iii, p. 227.) Further details are given in other tables, at pp. 224-25 of the Journal. But Hemp of far greater strength is produced in these, which are probably the native hills of the plant. Mr. Williams, of Jubbulpore, gave to Dr. Royle, in the year 1858, a sample of Hemp, which he stated had been forwarded to him by D. F. Macleod, Esq., as the produce of Kote Kangra, in the Sikh Himalayas. This Dr. Royle has, in his Lecture and Experiments, as well as in communications with various individuals, called Kote Kangra Hemp. It is the fibre which is mentioned as not breaking with a weight of 400 lb., when China-grass from Assam broke with 320 lb. and Petersburgh Hemp with only 160 lb. It has, moreover, appeared to all the practical men who have since then examined it, as the strongest fibre with which they were acquainted.

Abstract of Report of Proof of Moorgahvi, Arracan, Deyra, and Jetee Rope, compared with Europe, Manilla, New Zealand, Sunn, and Coir Rope, in the order of Strength and Elasticity.

Master-Attendant's Office,
30*th December*, 1844.

A. B. CLAPPERTON,
1*st Assist. to the Master-Attendant.*

Dr. Jameson, in the above letter, observes, with regard to the so-called Kote Kangra Hemp, that he himself had brought it to Mr. Macleod's notice, and that it was not produced in the Kangra district, but in Kooloo and Lahoul, which are a little farther in the interior. Before concluding, we have to detail the method of cultivating and preparing Hemp in Europe, in order to contrast them with the practice of the East, and for the information of those who may wish to cultivate it in this country. We are indebted for the directions to some of the most approved writers on the subject, and have contrasted them with those of Mr. Rowlandson in his paper in vol. x of the Journ. of the Royal Agricultural Society.'

Culture and preparation of Hemp in Europe.—Hemp being one of the few plants cultivated in Europe, which has the male and female flowers in different plants, affords some anomalies in its culture, especially that of having two harvests in the same crop. In some older works the male is frequently named the female plant, and *vice versa*.

Soil.—The soil, in which Hemp thrives, is a deep rich, moist soil, five or six inches deep; besides the alluvial, where sand and clay are intimately mixed, and having the above characteristics, also the friable loams, which contain much vegetable matter. All should contain a fair portion of sand, as this keeps the soil open and light for the roots to spread in. Hemp thrives well in Holland and Lincolnshire. Stiff, cold clays are unsuitable, for even if the plant should grow well, it is not easy to pull it "for when strong clay becomes saturated with rain, the soil runs together and on drying sets as hard as a pavement." If the soil be over-rich, the plant grows too luxuriantly, and produces a coarse but strong fibre. But Hemp is sometimes sown in such soils to meliorate them for the cereals, which would otherwise run too much to straw. But as many soils are too poor, they require to be raised to a suitable state by the addition of manure; and with this, it is said that Hemp may be grown in the same soil for many years. When a fine quality of fibre is required, of course, only the most suitable soil should be selected, or that in which the growth of the plant is neither excessive nor stunted. In Italy, Hemp is sown in their best lands, which are rich and strong loams, and made fine and friable. In Romagna, where the best Hemp is produced, they say it may be grown anywhere with manure. In the Himalayas, Dr. Royle has seen the Hemp growing most luxuriantly in the neighbourhood of bullock sheds, and producing fibre of great strength. In India, spots near the habitations of natives are the best adapted for the growth of Hemp; but in these they generally grow Tobacco. At Soonamooky it grew luxuriantly in sand, which was manured with stable-dung. Hence, Hemp grown in the plains will be dearer than the other fibres.

Culture and Manure.—But the richness of the soil, and the quantity of manure required must vary, not only according to the nature of the soil and its requirements, but also to the warmth of the soil and the nature of the climate. Warm, moist ones

require less than cold, whether dry or moist climates. In England, Mr. Rowlandson says, the generality of soil will require a dressing of ten tons of well-rotted farm-yard dung per acre, ploughed and harrowed in, early in April. He quotes an extensive grower, who says twenty-five tons of well-rotted, mixed stable and feedings-shed manure, should be applied per acre. The land should, of course, be in the first instance well ploughed and properly drained; also, well harrowed and rolled, to get the top-soil into good tilth; and weeds, as horse-mint, or twitch, destroyed. The manure must be carefully and evenly spread, and the plough follow close to the spreader.

Seed.—Of seed, that from Holland is the most esteemed, ripens soon, yields abundant crops, and of a fine quality; but well-grown English seed is also of good quality. Indian seed, from external appearance, appears fine; but may not be so well suited in the first crop for fibre; but the Himalayan seed, both from its appearance and the nature of its produce, is probably inferior to none, and perhaps only requires interchanging with different districts. The seed should be of a bright, grey colour, and plump: and must not have undergone heating in any way, and therefore the taste, when bitten, should be sweet, and not bitter or acrid. The quantity of seed may vary from two to two and a half, others say to three bushels an acre. The last, if a fine fibre is required for weaving into cloth. But the larger quantity cannot be sown on very rich soils. The thicker it is on suitable land, the finer it will grow. The fresh ploughed land should be sown very evenly, care being taken to scare away birds. The best time for sowing, in England, is from the 1st to the 15th of May; but it is sown even in June, as frosts are apt to injure the young plant; but late-sown plants are apt to grow thin and weak.

After-culture.—Hemp seed is sown both broadcast and in drills. When grown on account, chiefly, of the seed, it is sown thin. Sinclair says, by sowing Hemp in drills, a coarser and stronger bark or fibre, fit for cordage, will be produced, and a less quantity of seed is required than by sowing it broadcast. This latter mode is to be preferred, when Hemp is wanted for textile purposes. The stems rise slender and fine, according to their proximity; but they require to be weeded or hoed out to within a foot of each other, and may require a second hoeing, to destroy weeds; but in general the Hemp will, itself, smother all weeds, except in the spaces between drills. During its season of rapid growth, the plant necessarily requires moisture, and therefore, in some countries, irrigation is practised.

Pulling.—As already observed, Hemp has usually two harvests; but when grown on account of the fibre only, it may be pulled when in flower, and no distinction made between the male and female plants. But as it is usually desirable to get both the seed and the fibre of both plants, the male plants, or *white Hemp*, are pulled as soon as they have shed their pollen, usually about thirteen weeks after they have been sown. They may then be easily recognised by their leaves becoming yellow, and the stem of a whitish colour, and the flowers faded. Each plant is pulled up singly by the root, care being taken not to break or cramp the stem in the hand. The ripeness of the female plant is known not only by many of the same signs as those of the male, but also by the seeds beginning to turn of a grey colour, being firm inside, and some of the capsules to open. This is generally about Michaelmas in England. When the seed has become perfectly ripe, the bark is apt to become woody and coarse, and to separate with difficulty. But the seed which is required for sowing, ought to be taken from plants allowed enough of room to spread and then to fully ripen their seed.

Drying.—When the plants are pulled, it is recommended to hold the root end uppermost, and with a wooden sword dress off the flowers and leaves, as they assist in manuring the land. They are then bound in small bundles with bands at each end, of such a size that you can grasp with both hands, or sometimes into bundles of twelve handfuls each, and arranged along the borders of the field. If not done before, with a fork knock and shake off the soil from the roots, and scrape off the undergrowth of leaves. It is then set up like wheat in shocks, for a week or so. The stalks which form each handful should be as nearly as possible of an equal length, and the roots in particular should be placed as even as possible. If the crop is kept till spring, it is tied in larger bundles, and stacked and thatched.

Gathering Seed.—When the female Hemp is gathered, it is allowed to stand eight or ten days in the air, to allow the seed to dry and ripen; the tops being covered with undergrowth, to keep off the birds. After which, they cut off the heads, or gently beat out or thrash them to get out the seed, on a cloth. Care must be taken in conveying the bundles of seeded stems, as by passing a rope round the bundles and under the heads, and dragging the rope over the shoulder. The seed which remains after this operation, is got out by combing the heads on the teeth of a ripple; but the seed is inferior to that which first falls out, and is unfit for sowing. The female plant is generally stacked during the winter, and not steeped till the spring.

Drying.—When the Hemp has been pulled, it ought, according to some authorities, to be dried in the sun for one or two days, but Du Hamel observes, that it is a matter of doubt whether the plants should be dried before it is steeped; so Mills, in his 'Husbandry,' like the

natives of India with their Sunn (*v.* p. 274), thinks that this drying appears needless trouble. So Marcandier directs, that when the Hemp is perfectly ripe, it must be put into the water as soon as it is pulled out of the ground; and Sinclair says, that Hemp should be watered as soon as possible. In this state, it is said to require only four days, but, when it has been dried, eight days of steeping. The time must, moreover, depend a good deal on the temperature of the water.

Steeping.—The steeping of Hemp, called *Water-retting*, is a very important part of its preparation, and is to be distinguished from another method, which is called *Dew-retting*. The steeping places are often only ditches, three or four feet deep, varying in breadth and length, dug for the purpose on the margins of rivers. The bundles of Hemp are laid at the bottom of the water, and covered with straw, and sometimes with sods, and loaded with pieces of wood and large stones to keep them down. The object, as in the case of Flax, is by a slight degree of fermentation to enable the epidermis, or outer skin, to separate readily from the bark, and this from the boon or reed. This is readily ascertained, by taking out one of the steeped stems and holding it by the root end, and drawing the thumb-nail up the stem to the top. If the fibre slip up the stem, it is a proof that it has been sufficiently retted. Du Hamel, having steeped Hemp in different sorts of water, observes, that the fibres steeped in putrid standing water were softer than those which had been steeped in running water. But in water which does not run, the fibres contract a disagreeable colour: they are, however, notwithstanding this, easily bleached; it is desirable, however, to make a small stream of water pass through the steeping place. Du Hamel, referring to the common opinion, that Hemp intended for fine cloths should be retted more than that for coarse cloths, and that for making of ropes should be steeped least of all, observes, that though there may be some truth in this, it is in vain to hope greatly to improve, by this process, fibres which are naturally coarse. A fine fibre cannot be obtained without the concurrence of soil, of seasons, and of climate, the mode of sowing and of culture, and the degree of ripeness.

Drying after Watering.—When the Hemp is sufficiently retted, it is taken carefully out of the water, and then carried to a field of aftermath or any other grass (hence called *grassing*) that is clean and free from cattle. Here it is spread out very evenly, and will probably require to lie there for three weeks or more, in order to bleach and the fibre to become free; during which time it must be carefully turned over, with light long poles, every three or four days. Mr. Rowlandson says it is sufficiently bleached when pink spots appear on the stem. It is sometimes dried along a wall, or on rocky ground, and sometimes artificially, in ovens and kilns. When dry, the Hemp is tied up in bundles again, and carried to the barn or rick.

Peeling and Breaking.—When the Hemp is sufficiently dried, the next process is either to *peel* it, by taking one stalk after the other, breaking the reed, and slipping off the bark. The process is simple but tedious, and will give occupation to those who are without any. But it comes off in ribbons, which do not heckle so well as Hemp that has been broken, and they are apt to retain some of the thick parts next the roots, hence the saying, that this mode is better for the seller than the buyer. The term of breaking or braking Hemp, applies rather to the boon or reed than to the fibre, for this only bends under the hand of the dresser, and does not break. The operation is performed either by beating the Hemp, which is a laborious and tedious work, or by the break, which may be moved either by hand or by a spring or treddle attached to the upper jaw of the break, or by fluted rollers, worked by horse-, wind-, or water-, and now sometimes by steam-power. When Hemp has undergone the process of breaking, it is ready, like Flax, for the process of scutching, in which scutching mills are now used, as in the case of Flax. By rubbing, beetling, and striking the Hemp with reiterated blows, the longitudinal fibres are separated from one another, and in proportion to the greater or less degree of that separation the Hemp becomes more or less fine, elastic, and soft to the touch. (Du Hamel.) *Dew-retting* (p. 199), Mr. Rowlandson says (l. c., p. 186) will produce the most valuable white Hemp. The stems, after being pulled, are allowed to stand in the stooks for two or three days; they are then spread out on land where the grass is plentiful, and may require to be there for six weeks, and to be frequently turned. The process will be completed when the pink spots appear, as before noticed, which must be carefully looked for, when it will be ready to gather and tie up in bundles, to form stooks, in order to dry; the fibre will not sustain any damage before the pink spots appear. *Snow retting* is practised in Russia and Sweden. After the first fall, they spread the Hemp (which has been dried in the sun or otherwise) on the snow, and leave it there to be covered with other falls of snow, until spring, when it is usually found to be sufficiently retted. (Wisset, p. 194.) In Livonia they steep their Hemp in a manner which is a medium between still and running water, in a series of basins, one above the other, but as has already been observed, the French, for whom this information was originally obtained, do not avail themselves of it. (*v.* l. c., p. 204.) In addition to the ordinary methods of preparation of Hemp, we may briefly refer to others, most of which, however, have in improved forms been already noticed under the head of Flax. The Abbe Brulles re-

commended the use of soap in the proportion of one part to forty-eight of water, at a temperature of about 200° F., and the water to be about forty times the weight of the Hemp. Du Hamel tried boiling the Hemp stems in water, but he did not find that the peeling was facilitated. Marcandier recommended a second watering, and also the use of a warm alkaline ley (l. c., pp. 243 and 245). But as we have seen the use of hot water successfully applied to Flax in recent times, and soap has been used in several processes, and in a very ingenious manner in one which we omitted to notice,—that in which a little acid is afterwards added, so that decomposition takes place, in consequence of the acid uniting with the alkaline base, when the oil which is set free assists in softening the fibre. In the article on Sunn we have already referred (p. 276) to a peculiar method of drying, to which the Livonians are said to ascribe the good or bad quality of their Hemp. The stems are first set up to *drain*, and then spread out for a day to *dry*; after which they are made up in heaps, and covered over with straw, or other similar material of any kind, to make them *sweat*. When they have sweated *enough*, they are laid again in small heaps, so that the air may dry them in the shade by blowing through them; after which they are next effectually dried by fire, kiln, or oven, and immediately put under the breakers whilst yet hot. It is probable that this method, when skilfully practised, must produce some of the same effects in Hemp as in some other vegetable substances. Mr. Frushard observes, with regard to the natives of India: "The reason why their tobacco falls so much to dust, is owing to its not being *sweated* enough. When properly *sweated*, as they manage it in America, it becomes tough like a bladder; and toughness and suppleness are the qualities wanted in Hemp." (Wisset, p. 223.) Besides these, we have also the dry method of separating Hemp in some places, as related by Mr. Durno, who was the British Consul at Memel, and who states that in the southern parts of Poland, steeping is not practised at all, on the supposition that the harle is thereby weakened, and the colour darkened. Instead of steeping, they there *dry the stalks in the sun*. But the dressing is more laborious, and consequently more expensive. (Wisset, p. 177.) Mr. Dickson, as in the case of Flax, has succeeded admirably in separating Hemp fibre by passing dried stems from Italy under the rollers of his machine (v. p. 224), and Dr. Royle has no doubt that the method may be successfully practised with several fibres for many purposes.

Crop and Profit.—Mr. Rowlandson says the best land for obtaining fibre of the strongest description is a fat loam, not too heavy with clay, and a portion of sand intermixed. On such land, succeeding a crop of beans, Hemp will grow six or seven feet high, and bean-stalks in such make good manure for Hemp. He adds: "I have known 9 quarters of beans per acre after Hemp, weighing 21 stone per sack. Hemp after beans will produce 30 stone more per acre, of the strongest and heaviest fibre, than by any other mode of culture; the weight of fibre in ordinary culture and circumstances will produce 60 to 70 stone per acre." A good crop of Hemp after beans will produce 28 to 30 bushels of seed per acre; in the ordinary way, 20 to 22 bushels per acre. But only particular circumstances or prices render Hemp a desirable culture in England; for, in general, it cannot be considered a productive crop—though it may bring 5*s.* per stone, and good seed 5*s.* per bushel,—as it requires much manure, and "Hemp land will grow other crops of equal or superior value at a less cost." But other countries, such as parts of India and the Himalayas, which prefer any exportable produce like Flax or Hemp, will be glad to cultivate both, if they got any reasonable encouragement. The co-operation of a purely manufacturing establishment might facilitate and give advantages to the production of Hemp as well as to that of Flax.

Imports, etc., of Hemp from India.—It is not impossible therefore that as India now supplies England with the cheapest of fibrous materials, Jute, that the country will also be able to supply the strongest and best, that is, Himalayan Hemp. The greater distance which this has to travel, but chiefly by the Ganges River, may be easily paid for by its greater value. We also believe that as Mr. Deneef succeeded in growing some good Hemp even in the plains of Bengal in the rainy season, so others will be able to do so in other parts of India. The expenses of transit from distant parts will, no doubt, be diminished when larger quantities are operated upon and the arrangements are made by mercantile men. All such transactions in the Hills would be facilitated, if it were found possible to make the road from the Kemaon Hills into the plains practicable for light carts, as this has been done with the Sikh hills to some extent, but these are less precipitous. That there is nothing chimerical in the expectation of greatly increased quantities of fibre being imported, even from so distant a country as India, is evident from what has already taken place. If this has been possible with the cheaper it cannot be impracticable with the better. Though the information is not very certain, we find from the published reports that Hemp was exported from India to the following extent:

HEMP IMPORTED FROM INDIA, AND SOLD IN ENGLAND.

	cwt.		cwt.
1803	4820	1807	4738
1804	8335	1808	4023
1805	8399	1809	1543
1806	6421	1810	2555

In 1850-51 Imported into Bombay, of *Ganza*

(Hemp-herb), 514 cwt. from Concan; and Exported to the United Kingdom 15,895 lb.=Rs. 5,796. How greatly and rapidly the increase of fibrous materials has gone on within the last few years from India is evident from the following table of the imports from Russia and the British territories in India, from 1847 to 1851; while in the year 1831, 506,803 cwt. were imported from Russia, and only 9472 cwt. from the East Indies. Quantities of Hemp Imported into the United Kingdom from—

	1847	1848	1849	1850	1851
Russia,	544,844	540,207	641,548	614,535	672,342
Br. Ter in East Indies,	185,788	258,239	360,362	399,345	590,923

In successive editions of M'Culloch's 'Commercial Dictionary,' we find the following Imports into Great Britain; but, under the head of Hemp from India, are included the various Fibres described in this work, with probably no real Hemp, though this may be imported from thence.

Quantities of Hemp imported into the United Kingdom;

	1831	1847.	1851.
From Russia	506,803	541 341	672,993
„ British Territories in East Indies	9,472	185,788	590,523

In Russia as soon as Hemp is brought down in the spring, or in the course of the summer, it is selected and made up into bundles by sworn selectors (*brackers*), who are said to act with impartiality and exactness; and tickets are affixed to every bundle as selected, &c. Hemp at Petersburgh is assorted into clean Hemp, or firsts; outshot Hemp, or seconds; half-cleaned Hemp, or thirds; and Hemp Codilla. Riga Hemp is distinguished as resin (or clean), outshot, and pass Hemp. Particular care is taken to ship Hemp and Flax in fine, dry weather. If either get wet, they are apt to heat, and to be totally spoiled. For this reason every vessel taking in Hemp and Flax is furnished with mats to prevent their getting damp. A bundle of clean Hemp weighs from 56 to 65 poods; ditto outshot, 48 to 55 poods; ditto half-clean, 40 to 55 ditto. (1 pood=36 lb. avoirdupois) 63 poods are about equal to an English ton; the fixed charges on which in Petersburgh amount to 45 roub. 32 cop.; also commission and stamps, and on import into London, about £10 5*s.* 8*d.*, freight included; when the price is £40 a ton. (*v.* M'Culloch, from Mr. Borrison on the Commerce of Petersburgh.) With regard to prices, those of Hemp will of course vary at different times, like those of all other products. It is usually highest in the summer months, and lowest in September. In December, 1833, Petersburgh clean Hemp was 25*s.* to 26*s.*; Riga Rein at 29*s.* per cwt. In the year 1840, Italian Hemp was at 50*s* the cwt.; Polish Rein, 48*s.*; Petersburgh clean, 47*s.*; clean for cordage, 46*s.*; Polish Pass Hemp, 46*s.*; Petersburgh half-clean, 42*s.* In the year 1844, the price of Petersburgh Hemp was 38*s.* per cwt., or £38 per ton. At the end of 1854, Petersburgh clean, £60 10*s.* to £63; outshot, £59 to £61; half-clean, £57 10*s.*; Riga Rein, £61 to £64: do. outsthot, £58 to £63. But we cannot do better than conclude with an extract from the 'Commercial Circular' of the Messrs. Lindsay. "As regards Hemp, the rates for this article advanced in the early months of the year, and obtained their highest point in March, when £75 per ton was paid for clean. They then gradually fell to £58 to £60—about its present value—it having become apparent that supplies to a much larger extent than were anticipated would be received *via* Memel, &c. The future range of prices will, of course, necessarily depend on the action of our Government as respects Prussian neutrality. It, however, must not be lost sight of that the variety and extent of substitutes in the course of introduction will, under any circumstances, for some time to come diminish the consumption of Russian Hemp."—*Royle Fib. Pl. page* 340. At the Madras Exhibition of 1855, there were only four exhibitors of this fibre, the best and cleanest sample having been sent from Nellore: this plant does not thrive in Southern India so well as in the North West Provinces, and the colder parts of Bengal; it there produces a strong fibre suited for cordage and weaving, but in Southern India the Fibre deteriorates, and has little strength, it grows best at altitudes of 3 to 7000 feet. There are a number of Indian plants, which yield good substitutes for Hemp, some of which are extensively cultivated in the Madras Presidency. In China, *Hemp* is cultivated in the provinces north of the Meiling, but the plant also grows in Fuhkien; the grass cloth made from it is not so much used for common dresses as cotton and silk. There are three plants which produce a fibre made into cloth known under this name, viz. the *Cannabis sativa* or hemp at Canton, the *Urtica nivea*, a species of nettle grown about Suchan, and the *Sida tiliæfolia* near Tien-tsin-fu.—*Williams' Middle Kingdom, p.* 106.

(4292) HEMP SEED,

Sunn kee-beenge, Hind. | Chenevi, Fr.

The seed of the *Cannabis sativa*, *C. indica*, are albuminous and oily, and entirely devoid of all narcotic properties. They are used for crushing for oil.

(4293) HEMP SEED OIL. Cannabis sativa.

Ganja yenna, Tam.

This oil is obtained by expression from the seeds of the common hemp, which is cultivated in many parts of the country. In Russia, the oil is much used for burning in Lamps, but it is unknown to the natives of India. At the Madras Exhibition of 1855, three specimens were exhibited, one of a deep green colour from Tanjore, another of an olive green, sent by Lieut. Hawkes, and the third in the Madras Tariff.

(4294) HENBANE SEED.

Buzirulbung, Bung, Sikran, Urmanikou, ARAB.	Khorasanee ajwan, GUZ. HIND.
Khorasanie, CYNG.	Adas pedas, MAL.
Khorasanie-ajwan, DUK.	Adas, JAV.
Jusquiame, FR.	Hyoscyamus niger, LAT.
Bilsenkrout, GER.	Buzirulbung, PERS.
	Khorasanie omum, TAM.

The seeds are small, compressed, uniform, roundish, finely dotted, of a yellowish-gray colour, and have the odour of the plant and an oleaginous, bitter taste. The plant is a native of Europe and Asia Minor, and is extensively cultivated all over India. The chemical properties of the leaves and seeds have been carefully investigated, and an alkali has been obtained from it termed *Hyosciama*, but it differs little, if any at all, from *Atropia*.—*Faulkner*.

(4295) HENNA, LAWSONIA INERMIS. PRIVET EGYPTIAN.

Urkan, ARAB.	Henna, PERS.
Maritondi, CYNG.	Sakachera, SANS.
Mayndie, DUK.	Maroodanie, TAM.
Mendee, Henna, GUZ. HIND.	Gorunta Chettoo, Ivenie, TEL.
Daunlacca, MAL.	Mendi, BENG.

A reddish brown substantive dye, procured from the leaves of the Egyptian Privet (*Lawsonia inermis*). The Mahomedans in India, Persia, Arabia and other countries, use the shoots for dyeing the nails, tips of the fingers and toes, and palms of the hand, red. It is employed in the East for dyeing ordinary stuffs; and the extract of the flowers, leaves, and shoots, is used by the hakeems in lepra, and in obstinate cutaneous diseases.—*Faulkner*. The Henna tree, Lawsonia alba, Linermis, is the camphire of the English Bible, and the cypress shrub of the Greeks and Romans. "The cypress plant," says Rosenmuller, "is held in particularly high esteem by the Greeks, the Arabs, and the Turks; and they think that they make an agreeable present when they offer a person a posy of its flowers. In reality, this plant is, as Sonnini observes, one of those which are particularly agreeable to the eye and the olfactory organs. The flowers, of which the coloring is so soft, spread the most delightful fragrance to a great distance, and fill with balsamic odour the gardens and rooms which they adorn." It is extensively cultivated by the Burmese, and hedges formed of it are common in Bengal. The fresh leaves, beat up with catechu,

"Imbue
The fingers' ends with a bright roseate hue,
So bright that in the mirror's depth they seem
Like tips of coral branches in the stream."

This use of the leaves is as old as the Egyptian mummies, and is still practiced by Southern Asiatics.—*Mason*.

(4296) HEERA-KUSSEES, DRY PER-SULPHATE OF IRON. Is brought via Pali, used in dyeing and in making ink, blacking leather, &c. is only used in medicine made into, "missi" to apply to the teeth viz., to make

Black missi.—Heera-kussees, chaipal harra, choonigond, lila tootiga, iron filings, kuth, equal parts, pounded and mixed: rubbed on the gums.

White missi.—Sufaid soorum (crystallized carbonate of lime double refracting spar), and cinnamon pounded together: used as tooth powder.

Sada-kussees.—Impure sulphate of iron, the refuse from the manufactory of the sulphate of copper: four seers for one rupee.—*Gen. Med. Top. p.* 137.

(4297) HERITIERA ATTENUATA. One of the best and most plentiful of the jungle fruits is the heritiera. It grows in bunches resembling large grapes, is agreeably sub-acid, and when ripe, of a yellowish hue. The tree is small, and when arrayed with these long golden bunches it is very beautiful. It would be quite an acquisition to gardens both for ornament and utility. —*Mason*.

(4298) HERITIERA FOMES. See H. MINOR and LITORALIS.

(4299) HERITIERA MINOR AND H. LITORALIS.

KANAZOE, BURMESE.

These species are common in the Rangoon district, along the creeks and Sunderbunds. They afford the Soondree wood so well known in Bengal for its strength and durable qualities. It is a red-colored wood, strong and adapted for house-building.—*McClelland*.

(4300) HERITIERA MINOR. *Syn.* H. FOMES SOONDREE. The soondree is a gloomy looking tree that may be distinguished from all others for many miles distant. It is remarkably characteristic of a peculiar soil. Wherever the tides occasionally rise and inundate the land, this tree is sure to be found throughout the whole Tenasserim Coast, but it is never found at home, either on the high dry lands, on the one hand, nor in the wet mangrove swamps, on the other. It is the tree which was described by Dr. Buchanan Hamilton, who accompanied Symes' embassy, as *Heritiera Fomes*. It is the toughest wood that has been tested in India. When Rangoon teak broke with a weight of 870 pounds, Soondree sustained 1312 pounds. It is not a very durable wood, but stands without a rival in strength. Although so common on the other Coast, as to give name, as Captain Munro thinks, to the Soonderbunds, yet the tree grows much larger in these Provinces, and affords finer timber. —*Mason*.

(4301) HERMODACTYL SOORINJAN TULKH. Bull or cormus of an uncertain species of Colchicum.—*Irvine*. The Hermodactyl. In the medicine shops of India generally, there

are sold two varieties of a bulb called *soorinjan*, one the *S. tulk*, or bitter, the other *S. shereen*, or mild; both are identical with the Hermodactyls of the ancient Arabian and Greek writers. Their origin is unknown, but they are doubtless referable to some species of colchicum. The *tasteless* variety is about one inch long and the same in breadth, heart-shaped, rather flattened, grooved at one side, convex at the other. They are not wrinkled, and are easily broken and form a white powder. The *bitter* kind is smaller, and has a striped appearance. Pereira describes one of Mr. Royle's specimens as yellowish, somewhat transparent, horny, and striped lengthwise. No satisfactory experiments, whether chemical or clinical, have been yet made with this article. In some trials Dr. O'Shaughnessy made with an acetous tincture of the *soorinjan tulk*, he was led to believe it possessed of all the virtues of the dried colchicum of Europe. It certainly deserves careful and extensive examination.—*O'Shaughnessy, page* 661.

(4302) HERNANDIA SONORA.

Bongko, Jav.—*Ainslie.*

This is a native of various parts of the East and West Indies. It is a tall erect tree, fruit a dry drupe, calyx very large, inflated, with a small roundish mouth. The wind blowing over this aperture causes a whistling sound, whence the specific name is derived; the kernel is oily and purgative. The bark, seed, and young leaves are indeed all aperient; the fibrous roots are reputed to be an antidote to the Macassar poison. The juice of the leaves is described as a powerful depilatory, *(*Lindley.*) Rumphius says, that in Java the root is deemed a certain antidote to poison. This of course is but an imaginary property.— *O'Shaughnessy, page* 537.

(4303) HERMIT-CRAB. Pagurus. The common English name for the well-known crustaceans that occupy the empty turbinated shells of testaceous mollusks.

(4304) HERNANDIACEÆ, a natural order of incomplete Exogenous Plants. It has monœcious or hermaphrodite flowers, with an involucellum in the pistiliferous and hermaphrodite flowers; a petaloid calyx, tubular, 4-8-parted, deciduous; definite stamens inserted into the calyx in two rows, of which the outer is often sterile, with the anthers bursting longitudinally; the ovary superior, 6-celled, with a pendulous ovule and peltate stigma; a drupaceous fruit with one seed, which is pendulous; the embryo is inverted, without albumen; the cotyledons somewhat lobed, shrivelled, and oily. The species are trees with alternate entire leaves, and flowers arranged in axillary or terminal spikes or corymbs. This order has been constituted by Blume. It contains only two genera *Hernandia* and *Inocarpus*. These were sometimes referred to *Myristicaceæ*, from which they differ in the absence of albumen from their seeds. Their longitudinal anthers distinguish them from the *Lauraceæ*, in which order they have also been placed. Their affinity is undoubtedly with *Thymeleaceæ*, from which they differ only in their drupaceous fruit, lobed cotyledons, and the involucel to some of the flower. *Hernandia*, the typical genus of this order, was named after Hernandez, a naturalist sent out to Mexico by Philip II. of Spain; and it is said to have been given to these plants, which have large leaves and little flowers, in allusion to the great opportunities afforded to this naturalist and the little use he made of them. The characters of this genus are the same as the order. *H. sonora* is a tall erect tree, with cordate peltate leaves, yellowish, panicled flowers, a large inflated, succulent calyx, with a small, roundish entire mouth. It is a native of the various parts of the East and West Indies, and has obtained its name 'sonora' from the noise made by the wind in whistling through its persistent involucels. The bark, the seed, and the young leaves of this tree are slightly cathartic. Rumphius says that the fibrous roots chewed and applied to wounds infected with the Macassar poison, act as an effectual cure. The juice of the leaves is employed as a depilatory. It destroys the hair wherever it is applied, and this without producing pain. The wood of this species is very light, and Aublet says that the wood of *H. Guianensis* takes fire readily from a flint and steel, and may be used as tinder. Several species of *Hernandia* are mildly purgative. (Lindley, *Natural System;* Lindley, *Flora Medica*; Burnett, *Outlines of Botany.*)

(4305) HERPESTES (Illiger,) a genus of Digitigrade Carnivorous *Mammalia*, allied to the Civets. It is the *Ichneumon* of Lacepede, Geoffroy, and others; the *Mangusta* of Olivier and others; the Mangouste of the French and the mongoose of the English. It has the following characters:—Feet short, with 5 demipalmated toes, armed with claws which are slightly retractile; tongue furnished with horny papillæ; ears small; a voluminous simple pouch, which does not contain odoriferous matter, and at the bottom of which the vent is pierced. Body very much elongated; tail long, strong at its base. Hairs of the fur annulated. Dental formula:—

$$\text{Incisors},\frac{6}{6};\ \text{canines},\frac{1-1}{1-1};\ \text{molars},\frac{6-6}{6-6} = 40.$$

Mr. Bennett has noticed some peculiarities in the dentary system of these animals. In *H. fasciatus* and *H. Gambianus* he found the following arrangement:—

$$\text{Incisors},\frac{6}{6};\ \text{canines},\frac{1-1}{1-1};\ \text{molars},\frac{5-5}{5-5} = 36.$$

This is a system of dentition which as far as I am aware is altogether peculiar, and if confirmed by

the examination of other specimens will undoubtedly form the type of a new genus. Perhaps further and more rigid examination may even detect different species from the different localities, as specimens have arrived for the Society from Travancore and Bombay, and one from Madras, at the British Museum."

(4306) HERPESTES ICHNEUMON, the Ichneumon (*Ichneumon Pharaonis*: *Viverra Ichneumon*, α, of Linnæus). The fur a mixture of chestnut-brown and yellow, each hair being annulated with those two colours; the feet and muzzle black or deep chestnut; the tail terminated by a tuft of long hairs. This appears to have been one of the sacred animals of the ancient Egyptians; and we read in Herodotus (ii. 67) that the *Ichneutæ* (ἰχνευται), which the best critics consider to be synonymous with Ichneumons, were, as well as dogs, buried "in holy repositories." There is no good reason to doubt that it is the Ichneumon (Ἰχνεύμων) of Aristotle ('Hist. Anim.,' ix. 6; vi. 20, 35), Diodorus Siculus, Strabo, Ælian, and others; and as little that it is the *Ichneumon* of Pliny. Aristotle (ix. 6) relates, that when the Ichneumon sees the serpent called the Asp or Aspic (Ἀσπίς), he does not attack it till he has called to his assistance other ichneumons, and in order to defend themselves from the venomous bites of the snake, they cover themselves with mud by rolling on the earth after having dipped themselves in the water. Pliny ('Hist. Nat.,' viii. 24) gives a somewhat similar account. Diodorus and Strabo relate a much more marvellous feat; nor is Pliny slow to lend his aid in spreading the wonderful tale, how, when the crocodile is lulled asleep with open jaws, the Ichneumon darts like a weapon down his throat and gnaws his entrails ("erodit alum"). ('Hist. Nat.,' viii. 25.) It may be thought hardly worth while to refute such a fable; but it was long entertained as credible, and it may not be amiss to turn to Sonnini's observations on this point, more especially as they contain some interesting remarks on the habits of the animal. "Much," says Sonnini, who speaks of the Ichneumon as one of those animals which the Egyptians have domesticated,) "has been written concerning it, and much of this writing has been fabulous. It was one of the animals held sacred in ancient Egypt. Honours were rendered to it on its death: it was maintained with the greatest solicitude during life; funds were set apart for its support; they served up to it, as to cats, bread steeped in milk, or fish of the Nile cut down into morsels; and it was generally forbidden to kill any of the race. Object of the worship of a celebrated people, the pretended protector of the most singular country in the world against a scourge the most grievous to an agricultural nation, a stranger and unknown in our climates—what a field for the production of the marvellous? Accordingly it has not been spared. The greater part of travellers have seen the Mangouste without examining it; and with their minds prejudiced by the stories which the ancients and the moderns have spread respecting it, they have successively copied their relations." Sonnini then after a compliment to Buffon, and a statement that he had had it in his power to observe the Mangouste in its native country and in its state of liberty, proceeds as follows:—"With very great disposition to familiarity, the Mangoustes are not altogether domestic in Egypt. Not only do they now rear none in their habitations, but the inhabitants have not even the recollection that their ancestors reared any. Most probably then those which Belon and Prosper Alpin assert that they had seen domesticated were merely a few individuals preserved rather as objects of curiosity than for any useful purpose; for if they hunt away rats and mice, they likewise seize upon the poultry; and this appetite would more than overbalance the good which they could do in purging the houses of noxious animals, which cats would destroy more certainly and with less inconvenience. Having some resemblance in their habits to weasels and polecats, they feed upon rats, birds, and reptiles. They ramble about the habitations of men; they even steal into them, in order to surprise the poultry and devour their eggs. It is this natural fondness for eggs which prompts them frequently to scratch up the sand with the intention of discovering those which the crocodiles deposit there, and it is in this manner that they prevent, in reality, the excessive propagation of these detestable animals. But it is absolutely impossible to abstain from laughing, and not without reason, when we read of them leaping into the extended mouths of the crocodiles, of their sliding down into their belly, and not returning till they have eaten through their entrails. If some Mangoustes have been seen springing with fury on little crocodiles presented to them, it was the effect of their appetite for every species of reptiles, and not at all that of a particular hatred, or of a law of nature, in virtue of which they would have been specially commissioned to check the multiplication of those amphibious animals, as many people have imagined. It had been equally reasonable to say that nature places Mangoustes on earth merely to prevent the too great propagation of chickens, to which they are far more hostile in reality than to crocodiles. And what proves more clearly that men have been mistaken in ascribing such intentions to nature respecting Mangoustes is this—in more than half of the northern part of Egypt, that is it say, in that part comprised between the Mediterranean Sea and the city of Siout, they are very common, although there are no crocodiles there: whilst they are more rare in Upper Egypt, where the crocodiles are, in their turn, more numerous. The Mangoustes are nowhere more multiplied than in

Lower Egypt, which, better cultivated, more inhabited, more humid, and more shaded, presents also more abundantly the means of supplying them with prey and with food, and crocodiles never appear there."—*Eng. Cyc.*

(4307) HERRINGS.

Haringen, Dut.	Arenques, Port.
Harengs, Fr.	Seldi, Rus.
Haringe, Heringe, Ger.	Arenques, Sp.
Aringhe, It.	

A well-known fish, measuring from 8 to 12 inches in length, and weighing generally about 5½ ounces. It dies almost the instant it is taken out of the water. Herrings are met with in three different forms: *fresh herrings* are the condition in which they are taken from the sea; *white* or *pickled herrings* are merely salted, and put into barrels; and *red herrings* are gutted and salted, and afterwards hung up, and fired with the smoke of green wood.

(4308) HEUDELOTIA AFRICANA, or African Bdellium tree.—*O'Sh. p.* 287.

(4309) HEVEA GUIANENSIS. Caoutchouc plant. Siphonia elastica, *Syn.* Trunk 17 to 20 yards high, scaly like a pine apple, very straight, branched at the summit. Incisions in the bark cause the discharge of a juice which concretes into the well known and very valuable *caoutchouc* of commerce, a product however of many other trees in this and allied families, for example of Jatropha elastica, Ficus Indica, Artocarpus integrifolia, Urceola elastica, &c. The juice when first obtained is white and milky, spec. gr. 1.011 spread in thin layers it quickly dries into a colourless and often transparent solid substance. Pure caoutchouc is pale yellow, inodorous, tasteless. The ordinary black colour is attributed by some writers to its being smoke-dried, but specimens prepared by mere exposure to the air, have assumed the black colour. At 32° caoutchouc is hard, at 60° to 100° flexible like leather, and exceedingly elastic and adhesive. Sp. gr. 0.938.—*O'Shaughnessy, page* 560.

(4310) HIBISCUS, so named from one of the Greek names (*Ιβισκος*) of the Mallow, a genus of Plants belonging to the natural order *Malvaceæ*. The species, upwards of 100 in number, of this genus, are chiefly herbaceous, though of a large size, but a few are perennial and arboreous. They abound in the hot parts of Asia and America, and also in Africa and the tropical islands; a few extend into Europe, North America, and to the Cape of Good Hope. *H. Trionum*, which occurs in Europe, is also found in Cashmere. The genus is characterised by having an exterior many-leaved calyx; carpels united into a five-celled capsule; valves with the partitions in their middle; cells many-seeded, or very rarely containing only a single seed. The species are remarkable, like the family to which they belong, for abounding in mucilage, and for the tenacity of the fibre of their bark, whence several are employed for many economical purposes in the different countries where they are indigenous. The abundance of mucilage in some of the species renders them useful as articles of diet, as the unripe fruit of *H. esculentus*, the Okro or Gombo of the West Indies, which is employed both for thickening soup and as a vegetable; so in India *H. longifolius*, there called Ram Turai, is similarly employed, and much approved of by many Europeans, but objected to by others on account of its clamminess. The calyxes of *H. Sabdariffa* as they ripen become of a red colour and are pleasantly acid, whence in the West Indies the plant is called Red Sorrel. The calyxes are employed there, as well as in India, for making tarts; and a decoction of them, sweetened and fermented, is described in Browne's 'Jamaica' as a cool and refreshing drink, much used in many of the sugar islands. *H. Syriacus* and *H. Rosa Sinensis* are known as ornamental plants: the flowers of the latter are employed for blackening the eyebrows, as well as leather, both in India and China. The species of *Hibiscus* are chiefly useful for the tenacity of their fibre, and hence several are employed in rope-making. Thus *H. cannabinus* is cultivated everywhere in India in the rainy season for this purpose; and its fibre is often imported into Europe as a substitute for hemp. It is known by the name Sunn in Northern India, Ambaree in Western India, and Mesta Pat in Bengal. In the island of Otaheite rope and string are manufactured from the bark of *H. tiliaceus*, which is also made into matting of a white colour, and different degrees of fineness. Forster states that the bark is also sucked as an article of diet, when the bread-fruit fails there: it is also so employed in New Caledonia. Indeed the mucilage which all these plants contain will no doubt afford some nourishment. In the West Indies, the whips with which the slaves were lashed were made from the fibres of *H. arboreus* (Mohoe or Mohaul). The bark of so many species of this genus being used for its tenacity, it is impossible to enumerate all. Dr. Roxburgh particularly recommends the cultivation in India of *H. strictus*, in consequence of its long, fine, and strong fibres, of a beautiful glossy white appearance, and as likely to be an advantageous substitute for such as are already cultivated for this purpose.—*Eng. Cyc.* *Hibiscus clypeatus* and *elatus* are similarly employed in the West Indies; *H.* (now *Thespesia*) *populneus* & *H. tiliaceus*, already mentioned, in the Society and South Sea Islands; *H. Manihot* in Japan; *H. heterophyllus* in New Holland; and *H. verrucosus* in Senegambia.—*Royle.* Many of the Hisbiscus species are showy flowering plants, and thrive well in any garden soil; they are easily propagated by cuttings or layers.—*Riddell.* Dr. Wight in Icones, gives the following species of Hibiscus, viz. hir-

tus, 41 : lampas, 5 ; lunarifolius, 6 ; populneus, 8 ; pruriens, 6 ; Surattensis, 197.

(4311) HIBISCUS ABELMOSCHUS, so called from Hab-ul-Mooshk, the Arabic name of its musk-scented seeds, is now often named *Abelmoschus moschatus*, and formed into a new genus. Its seeds are said to be added to coffee in Arabia, and are in India employed as a cordial medicine. The plant abounds in mucilage, and is employed in the process of clarifying.—*Eng. Cyc. H. Abelmoschus*, in Hindee *mooshkdana*, or musk seed, is called *calee kustooree* in Bengal. The plants abound in mucilage, and are much employed in the North-West of India in clarifying sugar. The stems were cut when in flower by Dr. Roxburgh, and steeped immediately : for the result of his experiments. See FIBRES.—*Royle.*

(4312) HIBISCUS CANNABINUS. HEMP LEAVED HIBISCUS. Lin.

Poolchei keeray, also Casseric keray TAM.	Ghongoo koora, TEL.
Umbare ke baujee, DUK.	Garnikura, SANS.
Ambaree, in WESTERN INDIA.	Punday & pundrica, CAN.
Palungoo, MADRAS.	Maesta paut, of the BENGALESE.
Pooley Numajee, COIMBATORE.	Sunnee, at SAHARUNPORE.
Gongkura, of the TELINGAS.	Wilaitee, (or foreign) Sunn, at MUTTRA.
	Deckunee Hemp, of BOMBAY.

From the variety of synonyms which we have given of this plant, it is evident that it must be generally known all over India ; but from its having several distinct names of its own on the west, we should infer that it was a native of that side of India, or of the southern part of the Peninsula, as on the Bengal side its names are modifications of those of some of the other fibres. In Bombay, besides *ambaree*, its fibre is sometimes called Deckanee Hemp, to distinguish it from the *taag* or Conkunee Hemp (*Crotalaria juncea*). But it is very generally cultivated by the natives, though not in large quantities. This plant, found as yet only in a state of cultivation, is a herbaceous annual of about three months' duration. The stem is straight and simple, of from three to seven feet in height, with here and there a few inoffensive prickles, otherwise smooth. The leaves are spreading, alternate, with long, slightly prickly footstalks ; all are smooth, with their margins serrated ; but the lower leaves are heart-shaped ; those about the middle of the plant three-, four-, or five-lobed, with lanceolate acute lobes ; while the leaves at the top are simply linear-lanceolate. Stipules awl-shaped. The flowers are solitary, with short peduncles in the axils of the leaves ; very large : of a pale sulphur colour, with a deep purple centre. Of the double calyx, the outer is seven to eight-leaved, each subulate, spreading, and inserted near the base of the inner calyx. This is five-cleft, divisions sharp-pointed, bristly, and glandular near the margins, and with a large gland on the middle of each division. The stamens numerous, with their filaments united into a hollow column. Anthers one-celled, bursting by a transverse chink. Styles equal in number to the ovaries, and rising through the staminal columns. Carpels joined into a five-celled, five-valved capsule, with few seeds in each cell. Dr. Roxburgh says of this plant, in his 'Coromandel Plants,' vol. ii, p. 48, tab. 190, where a beautiful plate is given : "It is much cultivated by the natives. Its leaves are in general used as an esculent vegetable, and taste something like sorrel. The bark is replete with strong and tolerably soft fibres, and is employed as a substitute for Hemp, to which it is much inferior both in strength and durability. The usual time of cultivation is the cold season, though it will thrive pretty well at all times of the year, if it has sufficient moisture. A rich loose soil suits it best. The seeds are sown about as thick as Hemp, but generally mixed with some sort of small or dry grain, rendering it necessary to be sown very thin, that the other crop (which is one of those grains that does not grow nearly so high) may not be too much shaded. It requires about three months from the time it is sown, before it is fit to be pulled up for watering, which operation, with the subsequent dressing, is similar to that hereafter described for *Crotalaria juncea*." Dr. Roxburgh states, that he found the fibres to be stronger when obtained from full-grown plants that had ripened their seed, than when cut from plants in blossom. On the Coromandel Coast he found it cultivated, and a coarse sackcloth made of its fibres. In the Purneya district, Dr. Buchanan found it called *Ambya Patu*, on account of the acidity of its leaves, but in other parts *chandana*. In the southern parts the common cordage of the country was almost entirely made from its fibre. It was said to be sown in fields, which produce nothing else ; a practice which Dr. Buchanan had observed nowhere else in India. It appeared to him a coarse material in comparison with the fibre of the Corchorus, but he had no opportunity of trying its strength. In some places a few of the seeds are scattered about among other crops on account of its leaves. In Behar he found it called *Kudrum*, and cultivated only for being made into ropes, and not as an acid seasoning. About 200 begahs were occupied with it. In Bhagulpore he found it cultivated nearly as much as the Corchorus. The natives considered ropes made of it stronger and more durable than those of the Jute ; but its fibres are harsher, and, as he thought, could be reduced to fine thread. In Goruckpore it was cultivated to the greatest extent, but always intermixed with the *urhur* or *Cytisus cajan*, and ropes made of it were used for agricultural purposes. In the Dinajepore district, Dr. Buchanan found it called *Mesta*, but

its bark never used for making ropes; the leaves only being used as an acid green, the taste being pleasantly acid, and not unlike sorrel. We find it equally cultivated in Central and Western India. It is mentioned as one of the plants employed for cordage at Hyderabad. Colonel Sykes, in his 'Statistical Report of the Dukhun' (British Assoc., 1837, p. 241), enumerates it as one of the plants cultivated in the wet season; and among his drawings of cordage plants there is an excellent one of this plant, as well as of *Agave vivipara*, there called *gayal*. Among dry or spring season cultivation, Colonel Sykes enumerates the *Taag* or *Crotalaria juncea*, its fibres being employed for ropes and for coarse canvas. In the Madras Presidency, a number of fibre-yielding plants are mentioned by their native names, but as these differ in every district and are not accompanied by Botanical names, it is impossible to determine to what plants they refer. We know that Dr. Roxburgh found *Hibiscus cannabinus* in cultivation on the Coromandel coast, and that a coarse sackcloth was made of its fibres. In Vizagapatam it is called Gunny fibre, and a coarse sackcloth and rope made of it. So Dr. Ainslie says, "with the nar, or tough stringy fibre of the bark of the Hemp-leaved Hibiscus, a valuable kind of cordage is made, of various thickness." In a late Minute (19th Sept., 1854) by the Madras Government on the subject of fibres, we find it stated, that "the fibres of the roselle (*Hibiscus cannabinus*), which is known to grow readily and without much care all over the Madras territories, have been found to be an excellent substitute for tow, now imported from Europe." As the plant is so universally cultivated over a vast tract of country for home consumption, nothing would be easier than to obtain a very large supply of its fibres, if they were required for any of the ordinary purposes of cordage. The natives would have nothing to do but to increase a cultivation to which they are already well accustomed in all parts of the country. Dr. Buchanan states, as the result of his experience in the lower provinces, that it is cultivated everywhere in India, on account of its leaves, which are eaten as a vegetable, and for its bark, which is most useful for making cordage. Dr. Royle has seen it in the same way very generally cultivated in the North-Western provinces, chiefly for cordage for domestic and agricultural purposes. Though so generally cultivated, its fibre is hardly if at all known as a distinct article of commerce, —the exports of Indian fibres from the three Presidencies being entered as Hemp, those from Calcutta only being sometimes distinguished as Sunn. With regard to its strength, it may be said that, speaking generally, the fibres of the species of Hibiscus are not so remarkable for strength as for fineness. Dr. Roxburgh, in his experiments, found that a line made of this fibre, from plants in blossom, broke with 115 lb., but with 110 lb. when the seeds were ripe; Sunn fibre, under the same circumstances, breaking with 130 and 160 lb. So in Dr. Wight's experiments, the fibre of *Hibiscus cannabinus*, which is sometimes called the Jute of Madras, broke with 290 lb., when Sunn (*Crotolaria juncea*) broke with 404 lb. Both these, like Dr. Roxburgh's specimens, were probably grown in the same climate. But in Dr. Royle's experiments, Sunn broke with 150 lb., when Brown Hemp broke with 190 lb.; but the Sunn was from Bengal, and the Brown Hemp from Bombay. There is, however, some uncertainty about this, because though no fibres can well appear more distinct than these two, yet Dr. Royle has in his possession fibres of a Crotalaria which are hardly to be distinguished from Hibiscus Brown Hemp. The Sunn fibre of Bombay was, even in Dr. Roxburgh's time, remarkable for its dark colour. But some specimens of *Ambaree* fibre, sent by Dr. Gibson as those af *Hibiscus cannabinus*, and which closely resemble those of some kinds of ordinary Brown Hemp, were favourably reported upon as follows, by Messrs. Enderby, then of the rope-manufactory at Greenwich. Dr. Royle lately received an equally fine, if not finer, because softer specimen, from Messrs. Noble; but this is probably the produce of *Crotalaria juncea*. Unfortunately the best specimens of fibre came tied up in the same bundle with some ordinary Brown Hemp, and with some dirty, uncleaned fibre. September 26th, 1844. We have received your samples of India Hemp, and are pleased to observe that we are likely to obtain an article from thence, that will go far to make England independent of Russia for the supply of that important commodity. The samples supplied have much the character of Italian Hemp, but is inferior to it in colour and softness of fibre. It will not, therefore, in its present state be applicable for fine purposes. We send you a sample of some of the Indian Hemp we had dressed; it appears very good, but not equal in strength to the generality of Russia Hemp; we feel, however, assured that it is capable of being got up in better condition. The present price of Italian Hemp is £32 per ton; Russia Hemp, £28 per ton; Manilla, £23 per ton; New Zealand, £15 per ton; and Jute, about £13 per ton. The Indian Hemp, as per sample, £20 per ton; at which price we should at this period be prepared to purchase. Yours very truly, C. H. G. Enderby. To Dr. J. F. Royle. The Ambaree Hemp is stated by Dr. Gibson to be treated like the Tag or Crotalaria, being cut in November, and stored away until leisure time arrives for stripping the bark. It is in common use for plough and cart ropes, and is esteemed by the natives as very inferior to that of the *Crotalaria juncea*. Some of the fibre sent to Hull to be reported on in the year 1840, was

thus spoken of: "A greater part of that by the 'Wanderer,' which is of similar quality to your Umbarree, or *Hibiscus cannabinus*, cannot be sold for £16 a ton in the Hull market, when Baltic Hemp meets a ready sale at £40. You will perceive how much depends on colour and staple. Prejudice is not wanting,—but that is giving way." (Agric. and Hortic. Soc of Western India 1842.) The length of the fibres of carefully cultivated Ambaree Hemp is from five to six feet; they are of a paler brown than ordinary Brown Hemp, harsher in feel, and stick more together, as if all the gum had not been washed out; but they are divisible into fine fibrils, possessed of considerable strength, and well calculated for rope-making, as also for coarse fabrics. But, though esteemed by some of the natives of the West of India, it is not so good as the best Brown Hemp of Bombay—mentioned in connexion with Sunn. The fibres of this Hibiscus and of the *Sunn* are not distinguished from each other, or from others, in the account of the Exports from the Ports of India, and these have been given under the head of Sunn, and also in that article some observations on the preparation of these Exogenous fibres in India, as well as on their prices, and the quantities in which they may be obtained.—*Royle p.* 259.

(4313) HIBISCUS. In the West Indies H. clypeatus and elatus are cultivated for fibres: H. Manihot in Japan. H. heterophyllus in New Holland, and H: Verucosus in Senegambia.

(4314) HIBISCUS COLLINUS (ERIOCARPUS OF D. C.), a native of the mountainous parts of the Northern Circars, of Peninsular India, where it is called *kanda-gang*, and where the natives use the bark as a substitute for Hemp. Under the head of this plant, Dr. Roxburgh states that he has often observed that most of the Indian plants of this family might be employed for the same purposes as Hemp, as the bark is tough, and may almost always be stripped off in long slips. *H. ficifolius* is a species which Dr. Roxburgh so named, and of which he received the seeds from the Moluccas. It was an annual, growing very tall, often 12 to 14 feet high, growing straight, with few branches. The fibres he describes as uncommonly beautiful, and rather stronger than sunn.

(4315) HIBISCUS ESCULENTUS. BANDAKYA. Lin.

Vendokai, TAM.	Ghendamoola, SANS.
Baynda, DUK.	Ram Turai; Dhenroos, HIND.
Bendakaia, TEL.	

This plant is very common. It yields long silky fibres possessed of considerable strength and pliancy, well suited for the manufacture of rope, string, gunny bags, and paper. It bears a considerable resemblance to the true hemp of Europe. In the Madras Presidency, this fibre is in considerable request, and a small export trade is carried on, under the name of Hemp. In the year 1853-54, the exports amounted to 6,112 cwt. valued at 27,113 rupees. When cleaned without steeping, they are soft and pliant, whitish yellow in color and very silky. It is said to be the Okro or Gombo of the West Indies, but Dr. Riddell considers the latter to be a different species. The capsules when green are eaten, boiled, or put into soups and curries, the inside being of a slimy consistence. The seed is sometimes put upon toast with pepper, butter and salt. With *Hibiscus esculentus*, the *Okhro* of the West Indies, is now united the *H. longifolius* of the East Indies, the *Bandikai* of Madras, the *Ram turai* and *Dhenroos* of Bengal; and the *Bammia* of the west coast of Africa probably does not differ essentially from these two. Of all these, the long, young pyramidal pods are filled when green, with a large proportion of mucilage, on which account they are gathered in that state, and cooked as a vegetable, being much esteemed by many, though considered too viscid by others. The fruit is also used to thicken soups in the countries where it is indigenous and in the South of France and in the Levant. The seeds may also be added like barley to soups, and have been recommended to be roasted as a substitute for coffee. The bark of these plants also abounds in fibre, which is of fine quality, as in many others of the same genus. Dr. Roxburgh cut the stems when the seed was ripe, and committed them to the steep a few days after.—*Royle.*

(4316) HIBISCUS FURCATUS, a native of the interior of Bengal, growing to a height of from 6 to 8 feet. The bark yields abundance of strong white flaxen fibres, but the prickliness of the plant renders it very troublesome to handle. The stems were cut when in flower, and steeped immediately.

(4317) HIBISCUS LAMPAS. A plant yielding fibres.

(4318) HIBISCUS MACROPHYLLA is very plentiful in the forests of the Pegu and Tounghoo districts. It is a tall slender timber, of three or four feet girth, and would do for boards and house posts. Wood, white-coloured, adapted to every purpose of house-building.—*McClelland.*

(4313) HIBISCUS MUTABILIS. The changeable Rose. A large shrub bearing white flowers in the morning, and changing to red in the course of the day: easily propagated by cuttings. —*Riddell.* This native of China, is common in gardens in India, and remarkable for the change in the colour of its flowers during the day. The fibres of the bark were found to be of a hard nature, and of a bad colour.

(4320) HIBISCUS POPULNEOIDES.

Parispeepil, HIND.	Moonee gungaray. TEL.

This species is much like the next. Mr. Rohde

found it in a few of the gardens of the Natives near Samalcottah : it flowers during the wet and cold seasons. This species is immediately to be distinguished from populneus by the glands in the axills of the nerves of the leaves, their waved border and long points, and by the double integument of the capsule, the innermost of which requires force and a sharp knife to open it, whereas in populneus it is single ; and can be easily broken by the pressure of the thumb and finger. Thistree will answer better for avenues, parks, &c., than populneus, because it is much higher to the branches, consequently gives a free circulation to the air. When wounded there discharges the same yellow juice as in populneus. —*Rohde M.S.S.*

(4321) HIBISCUS POPULNEUS. POPLAR LEAVED. NOW THESPESIA POPULNEUS.

Gengarani kurra,	Poorsam marum, TAM.
Paris ka har,	Parspipal, DUK.

The poplar leaved hibiscus or tulip tree. This is a large handsome tree with dark green shining leaves, the flowers yellow, shaped like a tulip, capsules when ripe hard and downy, and on being cut through a yellow pigment exudes, having the appearance of gamboge : propagated easily by seed, and the tree is well adapted from its ornamental appearance for avenues, or the road side.—*Riddell.*

(4322) HIBISCUS ROSA CHINENSIS. SHOE-FLOWER PLANT. Lin.

Sapatoo poo, TAM.	Kambang sapatoo, MAL.
Jasoon ka pool, DUK.	Jasoon, DUK.
Dasanie poo, TEL.	Jaba, SANS.

This plant is common in India ; the leaves are used as emollients, anodyne and gentle aperients ; the flowers, for giving a red tinge to spirituous liquors. The flowers are deep scarlet, and yield a juice which turns rapidly to a dark purple, and is very mucilaginous. Applied to soft, unsized white paper, this colour is nearly as sensitive a test for acid as the celebrated litmus.—*O'Shaughnessy, page* 218. *Ainslie.* Shoe flowers are sometimes employed for dyeing lilac colour but it does not appear to be permanent, they are also occasionally rubbed on leather for the purpose of blackening and polishing it in the same manner as we find them used in Batavia.—*Ain's Mat. Med. page* 198. With this flower the natives make Achar.—*Ainslie's Mat. Med. page* 260. The petals of the Hibiscus rosa sinensis are used in some cases to furnish a black liquid to dye the eyebrows, and at Batavia they are employed to polish shoes.—*Williams' Middle Kingdom; page* 285. In Tenasserim, this [illegible]d, flaming flower is extensively cultivated, and [illegible]s a very good substitute for "Day and Martin's blacking."—*Mason.*

(4323) HIBISCUS SABDARIFFA, OR ROZELLE. WEST INDIA SORREL.

Yera googoo, TEL.	ra, also Sheemay kah-
Kaserika, Poolychay kee-	leg-keeray, TAM.

Hibiscus sabdariffa, is said to be so called from its Turkish name, while in the West Indies it is called Red Sorrel, and in the Madras territories *rozelle* and *rouselle.* It is cultivated in most gardens, because its calyxes as they ripen become fleshy, are of a pleasantly acid taste, and are much employed for making tarts, as well as an excellent jelly. Brown states that they are employed in the West Indies for making refreshing drinks. The stems having been cut when in flower, and the bark stripped off, and steeped immediately, display a mass of fibres, in Dr. Roxburgh's specimens, some of which are still in the India House, with the ultimate fibres of a fine silky nature. The name *rouselle* is said to be a corruption of *oseille.* The dietetical uses of these species have been mentioned, in order to show, that if cultivated on account of their fibre, they would also be useful for other purposes.—*Royle.* The fleshy acid calyx of this plant is well known to yield excellent jelly, and very palatable tarts. —*O'Shaughnessy.* The leaves are used as greens, alone, and mixed with others. The calyx and capsules when freed of seeds are made into jellies, and tarts ; generally cultivated ; the flowers of this plant are very pretty, often cultivated in flower beds.—*Juffrey.*

(4324) HIBISCUS STRICTUS, was a new species described by Dr. Roxburgh, and which seems to be a native of the Rajmahl Hills, with a straight stem of from 6 to 14 feet in height, and a very smooth bark. It thrives luxuriantly with little or no care ; seed-time the beginning of the rains ; it is in blossom about their termination, and the seed ripens in December and January, soon after which the plants perish. Like many other of the Malvaceous tribe, the bark of this species abounds in flaxen fibres ; but in none have I found so large a quantity, equally beautiful, long, glossy, white, fine, and strong, as in this. To these promising qualities may be added the luxuriant growth, and habit of the plant, rendering it an object deserving of every care and attention, at least until the real worth of the material is fairly ascertained. From several years' experience, I find the best season for sowing the seed in Bengal, is just when the first rains begin, which is generally in May, in beds ; and when the plants are about six inches high, transplant them out in rows, about nine inches asunder, and about as much from each other in the rows. In 1801, I had forty square yards planted in this manner, which yielded thirty-three pounds weight of the naturally very clean fibres. Dr. Roxburgh's original specimens, still in the India House, are 9 and 10 feet in length, a fibrous mass, apparently easily stript off, and composed of fine and easily divisible fibres.—*Royle.*

(4325) HIBISCUS SURATTENSIS.
Kashlee-keeray, TAM.

A herbaceous plant with speckled prickly stems and yellow flowers; the leaves are used as greens, indigenous.—*Jaffrey.*

(4326) HIBISCUS TILIACEUS is the *Bola* of the Bengalese, common also on the Malabar coast, and supposed not to differ from *H. arboreus*, the *Maho tree* and *Mohaut* of the West Indies. These grow abundantly both in the West and East Indies. Forster states, that the bark of this species is sucked in times of scarcity, when the bread-fruit fails. The mucilage with which all these plants abound, will no doubt afford some nourishment. The fibres of its inner bark are employed for cordage by the inhabitants of the South Sea Islands, and by the American Indians: it is said to gain in strength when tarred. The Otaheitans make fine matting from it, and likewise manufacture it into ropes and cords. Voyagers relate that these filaments are adapted to any kind of cordage, even for the rigging of vessels, but rope thus made is not nearly so strong as that prepared from Hemp. The whips with which the negroes in the West Indies used to be punished, are said to have been made with the bark of this species.—*Royle.*

(4327) HIBISCUS VIOLACEUS. A climbing plant found in Burmah during the rainy season, affording a coarse strong fibre.—*McClelland.*

(4328) HIBISCUS VESICARIUS. Good samples of the Hibiscus vesicarius fibre or wild Ambarre were exhibited at the Madras Exhibition of 1855, by Captain Meadows Taylor.

(4329) HIBISCUS VITIFOLIA. A plant yielding fibres.

(4330) HICK. A very hard, fine, close, very uniformly grained, heavy, Ceylon wood, in colour resembling pencil cedar.

(4331) HICKORY. A tree (*Carya*) common in Great Britain, and growing extensively in many parts of the United States. It is chiefly employed for carriage shafts and springs, large screws, chair-backs, hoops, whip-handles, &c.—*Faulkner.*

(4332) HIDES.

Huiden, DUT.	Cuoja, IT.
Peaux, FR.	Pelles, PORT.
Haute, GER.	Koshi, RUS.
Chamroo, GUZ.	Pellejos, Pieles, SP.
Chumra, HIND.	

Signify generally, the skins of beasts, but the term is more particularly applied to those of large cattle, such as buffaloes, cows, bullocks, deer, horses, &c. Various kinds are distinguished; *raw* or *green hides* are those in the state in which they are taken from the carcass. *Salted hides* are those dressed or smeared with salt, alum, or salt-petre, to prevent them from putrefying; and

tanned or cured hides. Buffaloe, Cow, and Sheep's hides, both salted and tanned, are largely exported from India to England.—*Faulkner.* At the Madras Exhibition of 1855, the Tanned hides and skins exhibited were nearly all of excellent quality and could bear comparison satisfactorily with the same kinds of leather prepared in Europe. They had been thoroughly saturated with the tanning materials, were free from animal odour, and their sections did not shew the white line between the outer and inner surface, indicative in bad leathers of a hasty and imperfect inhibition of the tan liquor. The collection comprise the tanned hides of the Bison, Sambre, Bullock, Horse, Cow, Sheep, Goat, Kid, Dog, and Iguana. The last is the only kind requiring any special mention here, as all the others are well known articles of trade and commerce. The Iguana skins which have been tanned and dyed black, or left of their natural color, are thin, even, soft, tough, elastic and granular, or shagreen-like in external appearance. From the absence of gloss, the appearance of this leather is not much in its favour, but it bids fair to be a durable article for light slippers, and a good covering for the commoner kinds of instrument boxes, such as are still done over with shagreen.

Tanned and Colored Skins—for book-binding purposes and boot-linings, were generally even, soft and pliant, and very suitable for their intended uses. Some of the colored leathers were very brilliant.

Sheep and kid skins tanned white—were exhibited in much perfection.—None of the specimens were fine enough for the better kinds of gloves, but they were all as well-suited as European skins of the kind for the purposes of the Apothecary.

Parchment skins.—The parchment skins take ink very well, but were not in every respect satisfactory. Their texture was uneven, and they had an odour quite distinct enough to lead the Jury to infer that they would be very liable to putrefactive changes on the accession of damp weather.

Wash Leather.—The skins prepared with oil, in imitation of chamois or wash leather, were all excellent specimens of the kind, so far as thickness, softness, pliancy and color, were concerned. In all these respects they will bear comparison with the European article. But as every one of the leathers was tainted with the odour of the Fish Oil employed in their preparation, they could not be recommended for household purposes, such as cleaning plate, though found very suitable for cleaning grasses and harness. As Potass, Soda, and dry hare deodorizing air are abundant in this country, a very little additional care would ensure the production of a perfectly inodorous chamois leather.

Buff leather.—The Buff leathers for accoutrements were nearly all extremely good in quality and have an evenness and equa-

lity in thickness which must render them very economical leathers for manufacturing purposes. The best tanned leather from Buffalo, Bullock, and Cow hides, were contributed by Colonel Sheriff and Lieut. and Qr. Mr. Grant from the Horse Artillery Tannery at Bangalore. They also exhibited specimens of leather prepared from the Hog, Calf, Goat, and Sheep skins, of unexceptionable quality. The Jury considered these gentlemen deserving of a 2d Class Medal for the best tanned leather of all kinds.

(4333) HIERACIUM GRANDIFLORUM. This is a very extensive genus of plants all over Europe, the dwarf kind are best adapted for rock-work, flowers of a yellow colour with the exception of the aurantiacum, native of Scotland: increased by cuttings, and the herbaceous kind by dividing the roots.—*Riddell.*

(4334) HIMALAYA. A thousand feet above Punkabaree in the outer Himalayas, the prevalent timber is gigantic, and scaled by climbing Leguminosæ, as Bauhinias and Robinias, which sometimes sheath the trunks or span the forest with huge cables joining tree to tree. Their trunks are also clothed with parasitical orchids. And still more beautifully there with Pothos (*Scindapsus*), Peppers, *Gnetum*, Vines, Convolvulus, and Bignoniæ. The beauty of thedrapery of the Pothos-leaves is pre-eminent, whether for the graceful folds the foliage assumes, or for the liveliness of its colour.—*Hooker, Him. Jour. Vol.* I. *p.* 108. From one steppe, the ascent to Punka baree is sudden and steep, and accompanied with a change in soil and vegetation. The mica slate and clay slate protrude everywhere, the former full of garnets. A giant forest replaces the stunted and bushy timber of the Terai Proper; of which the *Duabanga* and *Terminalias* form the prevailing trees, with *Cedrela* and the *Gordonia* Wallichii. Smaller timber and shrubs are innumerable; a succulent character pervades the bushes and herbs, occasioned by the prevalence of *Urticaceæ*. Large bamboos rather crest the hills than court the deeper shade, and of the latter there is abundance, for the torrents cut a straight, deep, and steep course down the hill flanks: the gulleys they traverse are choked with vegetation and bridged by fallen trees, whose trunks are richly clothed with *Dendrobium Pierardi* and other epiphytical Orchids, with pendulous *Lycopodia* and many ferns, *Hoya*, *Scitamineæ*, and similar types of the hottest and dampest climates.—*Ibid* 281. The forest was truly magnificent along the steep mountain sides. The apparently large proportion of deciduous trees was far more considerable than Dr. Hooker had expected; partly probably due to the abundance of the *Dillenia*, *Cassia*, and *Sterculia*, whose copious fruit was all the more conspicuous from the leafless condition of the plant. The white or lilac blossoms of the convolvulus like *Thunbergia*, and other *Acanthaceæ* were the predominant feature of the shrubby vegetation, and very handsome. All around, the hills rise steeply five or six thousand feet, clothed in a dense deep green dripping forest. Torrents rush down the slopes, their position indicated by the dipping of the forest into their beds, or the occasional cloud of spray rising above some more boisterous part of their course. —*Ibid, Vol.* I, *page* 103.

(4335) HING.

Thunghsheen pan, Burm.

A gum which is well known under that name in the bazars of Bengal, is procurable from two species of *Gardenia*, which yield it in Bengal, and which are very common throughout the Pegu, Rangoon and Tounghoo districts.—*McClelland.* See Decamullee.

(4336) HIPPOCRATEA ARBOREA. Tree like Hippocratea.

Katha-puhariya, Hind.

Found in Kotah hill jungles.—*Genl. Med. Top. page* 173.

(4337) HIPPOPOTAMUS (Ἵππος & ποτάμος), the Roman name for the River-Horse, and retained by modern zoologists as the generic appellation of the animas of that Pachydermatous form.

Dental Formula:—Incisors $\frac{4}{4}$; canines, $\frac{1-1}{1-1}$; molars, $\frac{7-7}{6-6}$ = 38.

"The Hippopotamus now only exists in Africa; it is found in the rivers of the south and west, as well as in the Nile; and there is also in some of the western rivers a pigmy species, of whose skull a cast was presented to the Society by the late Dr. Morton of the United States." The uses of the Hippopotamous to man are certainly not many but when we look at the enormous ripping chisel-like canines of the lower jaw, and the lower incisors formed for uprooting, we cannot but think that such an animal must be an active agent in clearing rivers from the greater water-plants which might in time, if left undisturbed, go far to convert the running stream into a sluggish swamp. With regard to minor details, the flesh of this Wasser Ochs is much esteemed as an article of food. In the first catalogue of the African Museum we read that it is much in request both among the natives and the colonists, and that the epicures of Cape Town do not disdain to use their influence with the country farmers to obtain a preference in the matter of Sea-Cow's Speck, as the fat which lies immediately under the skin is called when salted and dried. Nor are the whips which are made of the skin of the Hippopotami of the Nile thought lightly of in the neighbouring countries. They are said to be made by cutting the fresh skin into triangular strips some five or six feet in length; one extremity of the strip is pointed, and it gradually widens till the breadth at the opposite extremity is equal to the intended circumference

of the hulk of the whip. The strip is then rolled up so as to form a sort of conical pipe, is firmly tied to keep it in place, and dried in the sun. When all is finished a light and elastic whip is produced. But there is no part of the hippopotamus in more request than the great canine teeth, the ivory of which is so highly valued by dentists for making artificial teeth. No other ivory keeps its colour equally well; and these canine teeth are imported in great numbers to England (where more are sent in the first instance than anywhere else perhaps) for this purpose, and sell at a very high price. From the closeness of the ivory, the weight of the tooth, a portion only of which is available for the artificial purpose above mentioned, is heavy in proportion to its bulk; and the article fetches, or did fetch, upon an average, about thirty shillings more or less, per pound. One of the specific distinctions pointed out by M. Desmoulins is the comparative abrasion of the canines in the supposed two species; and we would call the attention of the curious who deal in these teeth to this circumstance and the papers above quoted. —*Eng. Cyc.*

(4338) HIPPURINÆ, the order Hippurinæ furnishes the water caltrops (Trapa) the seeds of which are vended in the Chinese streets as a fruit, after boiling, the Chinese name means buffalo head fruit, which the unopened nuts strikingly resemble.—*Williams' Middle Kingdom, p.* 282.

(4339) HIPTAGE MADABLOTA, Delight of the Woods. Malpighiaceæ.

Bokhee or Utimookta, Duk.

A large climbing shrub, with very beautiful white and yellow flowers in terminal racemes: petals fringed; four white, one yellow;—one of the stamens much longer than the rest; fruit unequally three winged. The bark is a good sub-aromatic bitter.—*Riddell.*

(4340) HIRUDO, L. the Leach. Diploneura v. articulata. Class annelida. Hirudo medicinalis, Linn. L. D. Sanguisuga, Savingy. Leeches and their effects must have been known from the earliest times. They were early employed therapeutically by the Hindoos, and the Arabs adopted their practice. (*Royle. Hindoo Med. p.* 38, and Wise *Hindu Medicine*, p. 177.) Themison mentions the employment of Leeches by the ancients. Herodotus alludes to one kind, (*Bdella nilotica.*) Dr. Pereira infers that *Sanguisuga ægyptiaca*, the species from which the French soldiers in Egypt suffered, is that referred to in the Bible (Prov. xxx. 15) by the name of *Olukch* or *Aluka*. The latter, or *Aluk* is also the Arabic name for Leech. Leeches are included by Cuvier in the genus *Hirudo*. This has since been subdivided into several genera. Savigny calls that which includes the leeches used in medicine Sanguisuga, the *Iatrabdella* of Blainville. Leeches are characterised by having an elongated, plano-convex body, tapering towards both extremities, wrinkled transversely, and composed of from 90 to 100 soft rings. The mouth furnished with a lip, and the posterior extremity provided with a flattened disk, both adapted to fix upon bodies by suction, and to serve the leech as the principal organs of locomotion. Underneath the body two series of pores are observed, which lead to as many interior pouches, which are regarded as organs of respiration. The intestinal canal is straight, inflated from space to space, as far as two-thirds of its length, where there are two cæca. The blood swallowed is preserved there red and unchanged for many weeks. The subgenus *Sanguisuga* has the upper lip divided into several segments, the aperture of its mouth is tri-radiate, and it contains three jaws, each armed on its edge with two ranges of very fine teeth. Ten blackish points are observed on the head, which are taken for eyes. The anus is small, and placed on the dorsal surface of the last ring. The two species most commonly used, and which by some are considered varieties of one another, are *Hirudo medicinalis* and *H. officinalis*. H. Officinalis is distinguished by its unspotted olive green belly and by the dark green back, along which and the flanks are observed six longitudinal, often interrupted, rusty-red stripes. Six of the eyes are said by Savigny to be very prominent. Teeth about 70 in number. A native of the south of Europe, as of France and Germany. It is usually called the Green Leech, sometimes the Hungary Leech, from being a native of that country. H. medicinalis (fig. 95, 1 to 3), the kind usually employed in England, and readily distinguished from the foregoing by its belly, which is of a yellowish green colour, but covered with black spots, which vary in number and size, forming almost the prevailing tint of the belly, the intervening spaces appearing like yellow spots. On the back are six longitudinal reddish or yellowish red bands, spotted with black and placed on an olive green or greenish brown ground. The number of rings varies from 93 to 108. Teeth 79 to 90 in number. A native of almost all parts of Europe, often called the English, the speckled, the true, the brown Leech, &c. Other species are figured by Brandt, as *Hirudo provincialis, H. Verbana, H obscura*, and *H interrupta*. In the United States they use *H. decora*. In Southern and Northern India Leeches are extremely abundant, procurable both in the tanks of Bengal and in the north-west provinces, as well as along the foot of the Himalayas. Six kinds of useful and six venomous Leeches are mentioned in Susruta and by Avicenna, *l. c.*—*Uses.* Leeches are effectual for the local abstraction of blood, affording indeed the best method in many cases, as in inflammation of the abdomen, scrotum, in hæmorrhoidal tum-

ours, and prolapsus of the rectum. They may often follow general depletion; but, according to the quantity or the nature of the case will themselves produce constitutional effects, especially in the cases of children, They act by a sawing motion, and draw about 1½oz. of blood, though 3oz. may be obtained by fomentation, &c. Excess of bleeding may be stopped by pressure, application of Matica; sometimes caustic is required, and even sewing up the wounds with a fine needle.

(4341) HODGSONIA HETEROCLITA, *Hooker*; TRICHOSANTHES, *Roxburgh*. Hodgsonia is the most magnificent plant of the jungles in the valley of the Teesta in Sikkim. It is a genus dedicated by Dr. Hooker to his friend, Mr. Hodgson. It is a gigantic climber allied to the gourd, bearing immense yellowish-white pendulous blossoms, whose petals have a fringe of buff-coloured curling threads several inches long. The fruit is of a rich brown, like a small melon in form, and contains six large nuts, whose kernels (called "katior-pot" by the Lepchas) are eaten. The stem, when cut, discharges water profusely from whichever end is held downwards.—*Hooker, Him. Jour. Vol.* II. *p.* 7. And at other places Dr. Hooker says it is a new cucurbitaceous genus, found in the Terai, clinging in profusion to the trees and also 5000 feet up the mountains.—*Hooker, Him. Jour. Vol.* 1, *p.* 395. And further on, he says, This magnificent cucurbitaceous climber grows in the forests; east of Chittagong: it is the same species as the Sikkim one. The long stem bleeds copiously when cut, and like almost all woody climbers, is full of large vessels; the juice does not, however, exude from these great tubes which hold air, but from the close woody fibres.—*Hooker, Vol.* II, *page* 350.

(4342) HOG.

Hog, ENG.	Khunzeer, ARAB.
Babi, MALAY.	Soôr, HIND.

All the wild hogs in the Archipelago are small animals, compared with the wild boar of Europe, or even with that of continental India. The Sus verrucosus, so called from the fleshy excrescence on the sides of the cheeks, has a grotesque and a formidable appearance, but is in reality a timid animal. The number of them in Java is immense, and in passing along the highway, in particular districts, scores of them are to be seen.—*Crawfurd, Dict. p.* 152.—See SUS.

(4343) HOG'S LARD.

Adeps suillus, LATIN.	Soor ke churbee, HIND.

This is the fat about the loins of the hog, *Sus scrofa*. It is purified by melting and straining. Its melting point is from 78° to 88°. Fahrt.; inodorous and tasteless while fresh, readily grows rancid. Lard contains carbon 79·098, hydrogen 11·146, oxygen 9·756—proximately it consists of ealine 62, stearine and margarine 38 per 100. In the rancid state it contains the margaric and stearic acids, and a peculiar volatile acid. In Europe, hog's lard is much employed in ointments, but in India the strong prejudice against the article renders it desirable to exclude it as much as possible from all pharmaceutical preparations, substituting for it the "simple liniment."—*O'Shaughnessy, p.* 690.

(4344) HOG PLUM. SPONDIAS MANGIFERA.

(4345) HOLARRHENA CODAGA. APOCYNACEÆ, Icon. 1292.

Kooda pallie marum, TAM.

A white small sized wood and very fine grained employed in cabinet-making. Dr. Wight gives Holarrhena Malaccensis, in *Icones*. 1298.

(4346) HOLARRHENA PUBESCEN S Roora. Wood light. This species and the *H. antidysenterica* yield the *Indurjuo tulk* of the bazar. (See *Wrightia.*)—*O'Shaughnessy page* 449.

(4347) HOLCUS, a genus of Grasses belonging to the tribe *Aveneæ*. It has 2-flowered glumes, the lower perfectly awnless, the upper usually stameniferous, with a dorsal awn; the paleæ hardening on the fruit. There are two British species of this genus. *H. lanatus* has the upper glume obtuse, apiculate; the awn smooth, except for a short distance from the tip. It grows in meadows and pastures. *H. mollis* has the upper glume acute, and the awn rough throughout its whole extent. It grows in thickets or open places on a light soil. The *H. cernuus* of Willdenow, and the *H. sorghum* of Linnæus are now referred to the genus *Sorghum*. Fraas refers the Μέλινη of Theophrastus ('Hist. Plant.,' viii. 1. 3, 7, 10) to these grasses, and not the *Setaria Italica*, as had been done by previous authors. (Babington, *Manual of British Botany*; Fraas, *Synopsis Plant. Florœ Classicœ*).—*Eng. Cyc.*

(4348) HOLCUS SACCHARATUS. *Syn.* ANDROPOGON SACCHARATUS, Roxb. A native of Caffraria. Stalks thick, and full of a sugary medulla. Professor Arduino, (*Journ. Botanique*, iii. 168,) gives an account of his experiments on the extraction of sugar from this species. They were extremely satisfactory.—*O'Shaughnessy, p.* 637. This has been lately recommended in the United States as a sugar producing plant and for the sake of its juice. Its stalks furnish three important products, sugar, which is identical with that of cane,—alcohol, and a fermented drink analagous to cider. This juice, when obtained with care and in small quantities, by depriving the stalk of its outer coating or woody fibre and bark, is nearly colourless and consists merely of sugar and water. Its density varies from 1,050 to 1,075 and the proportion of sugar contained in it from 10 to 16 per cent, a third part of which is sometimes uncrystallisable.—*Am. Rep. Com. of Patents, page* 220.

(4349) HOLCUS SORGHUM. *Syn.* SORGHUM VULGARE: H. SACCHARATUS: ANDROPOGON SORGHUM.

Joar, Beng. & Hind.

Grown in fields and sown during the rains; it is the common food of the poorer classes, made when ground into cakes. A native of India, and cultivated in Peru, and in Europe; seeds very hard, rounded, very variable, sometimes entirely smooth, insipid, parenchyme farinaceous; but little different from maize in chemical composition. The stalks afford sugar, but in less quantity than the last species,—*O'Shaughnessy, page* 936.

(4350) HOLCUS SPICATUS. *Syn.* PENICILLARIA SPICATA, Willd.

Douranelle, Egypt. | Cambon, Tam.
Couz-couz, Africa. |

East Indies, cultivated in Europe—*O'Shaughnessy, p.* 637.

(4351) HOLIGARNA, a genus of Plants belonging to the natural order *Anacardiaceæ*. The berries of *H. longifolia* are manufactured in India into a well-known black varnish.—*Eng. Cyc.*

(4352) HOLIGARNA. Buch.

Biba Biba, Can.

Biba is, strictly speaking the Canarese name of the Chittagong Varnish tree, but the Natives of Canara, Dr. Buchanan informs us, are not as yet aware of its peculiar quality.—*Ainslie, Mat. Med. p.* 143.

(4353) HOLIGARNA LONGIFOLIA. *Roxb. Fl. Ind.* ii. p. 80, one of the trees yielding the well known black lacquer varnish.—*O'Shaughnessy.* This black varnish tree grows in the forests, of Tenasserim and on the other Coast, where the tree grows, its exudation is used by the natives to varnish shields, and for other purposes.—*Mason.* A fine black varnish from the fruit of *Holigarna longifolia*, is imported from Munnipore, as is another made from *Semecarpus Anacardium* (marking nut), and a remarkable black pigment resembling that from *Melanorrhœa usitatissima*, which is white when fresh, and requires to be kept under water. This turns of a beautiful black colour when applied to a surface, owing, according to Sir D. Brewster, to the fresh varnish consisting of a congeries of minute organised particles, which disperse the rays of light in all directions; the organic structure is destroyed when the varnish dries, and the rays of light are consequently transmitted.—*Hooker, Him. Jour. Vol.* II. *p.* 331.

(4354) HOLOSTEMMA RHEEDIANUM. Specimens of the flowers, leaves, immature pods, and stem, of a fibre-yielding plant, were presented by Capt. Hannyington, Political Agent at Purulea in Chota Nagpore, to the Agri-Hortic. Society in 1841. Capt. H. mentions that this plant is very abundant in the Hills about Purulea, and is also found in the neighbouring plains. It is known to the Coles by the name of *Apoong*. The fibre is said to attain its best condition after the rains. The Secretary mentioned that this plant was introduced into the Botanic Garden from Western India, and is well known to Dr. Wallich, who immediately recognized it as *Holostemma Rheedianum* of Sprengel, the *Ado-Modien* of the Hortus Malabaricus.—*Royle Fib. Pl. p.* 306.

(4355) HOLOTHURIADÆ, a family of animals belonging to the order Echinodermata.—*Eng. Cyc. Vol.* III, *page* 110. M. De Blainville's Echinodermata form the first class of his Actinozoa and the first order of that class consists of the Holothuridea, which are followed (Atinolagie, 1834) by the Echinidea, his second order, M. De Blainville thus defines the Holothuridea. "Body more or less elongated, sometimes subvermiform, soft or flexible on all sides, provided with tentaculiform suckers, often numerous, very extensible, completely retractile, and pierced by a great orifice at each extremity. Mouth anterior, at the bottom of a sort of funnel or prebuccal cavity, sustained in its circumference by a circle of fibro-calcareous pieces, and provided with a circle of arbuscular appendages, more or less ramified. Vent terminating in a sort of cloaca opening externally by a large terminal orifice. Generative organs terminating externally by a single mesial orifice at a little distance from the anterior extremity, and nearly marginal." In his 'British Star-Fishes,' Professor E. Forbes makes the following general observations on this family:—"A *Holothuria* may be regarded in one light as a soft Sea-Urchin, in another as a radiated animal, approximating to the Annelides. The radiation of the surface is more or less complete in all the genera of *Holothuriadæ*; the internal organisation is mostly bilateral. The skin is usually soft and leathery; in a few genera strengthened by calcareous or horny spines. Five avenues of suckers separate the body into as many longitudinal segments, which in the majority are of equal, or nearly equal dimensions. In some the suckers are developed only on one side, so that the animal when creeping presents in a manner a back and a belly. The suckers are similar to those of the true star-fishes and sea-urchins. Besides progression by means of these suckers, the *Holothuriadæ* move as Annelides, by the extension and contraction of their bodies. They have a mouth and an anus, each terminal, and placed at opposite extremities of their bodies. The mouth is surrounded by plumose tentacula, the number of which, when they are complete, is always a multiple of five; but as these animals are singularly subject to the loss or absence of parts in individuals of the various species, much confusion has arisen from the establishment of

suppositious species from characters founded on abnormal numbers of the parts. When Mr. De Blainville says that he has never heard that any of these animals were of much utility to mankind, but that M. Delle Chiaje does indeed inform us that the poor inhabitants of the Neapolitan coasts eat them, he appears to have forgotten the great oriental traffic carried on with some of the species, as an article of food, under the name of Trepang or Trapang, Biche-de-Mer or Beche-de-Mer. Captain Flinders fell in with a fleet of Malay proas at the English Company's Islands, north coast of Australia, near the Gulf of Carpentaria (1803), and was informed that sixty proas belonging to the raja of Boni, and carrying one thousand men, had left Macassar with the north-west monsoon, two months before, on an expedition to that coast. "The object of their expedition," writes Captain Flinders ('Voyage to Terra Australis'), "was a certain marine animal called Trepang. Of this they gave me two dried specimens; and it proved to be the Beche-de-Mer, or Sea-Cucumber, which we had first seen on the reefs of the east coast, and had afterwards hauled on shore so plentifully with the seine, especially in Caledon Bay. They got the Trepang by diving, in from three to eight fathoms water; and where it is abundant, a man will bring up eight or ten at a time. The mode of preserving it is this:—the animal is split down one side, boiled, and pressed with a weight of stones, then stretched open with slips of bamboo, dried in the sun, and afterwards in smoke, when it is fit to be put away in bags, but requires frequent exposure to the sun. A thousand trepangs make a 'picol' (of about 125 Dutch pounds); and one hundred picols are a cargo for a prow. It is carried to Timor, and sold to the Chinese, who meet them there; and when all the prows are assembled, the fleet returns to Macassar. By Timor seemed to be meant Timor-laoet; for when I inquired concerning the English, Dutch, and Portuguese there, Pobassoo (Captain Flinder's informant) knew nothing of them: he had heard of Coepang, a Dutch settlement, but said it was on another island. There are two kinds of Trepang: the black, called Baatoo, is sold to the Chinese for forty dollars the picol; the white or gray, called Koro, is worth no more than twenty. The Baatoo seems to be what we found upon the coral reefs near the Northumberland Islands; and, were a colony established in Broad Sound or Shoal-Water Bay, it might perhaps derive considerable advantage from the Trepang. In the Gulf of Carpentaria we did not observe any other than the Koro, or Gray Slug." Captain Phillip Parker King, who quotes a part of the above passage ('Survey of the Intertropical Coasts of Australia') found a fleet of Malay proas in the bay at Coepang (1818): it had just returned from an unsuccessful voyage on the south coast of Timor in search of trepang. Dramah, the principal raja of the fleet, gave Captain King the following information respecting the coast of Australia, which the raja had frequently visited in the command of a fleet that annually frequents its shores. The coast is called by them 'Marega,' and has been known to them for many years. A fleet to the number of 200 proas (but Captain King thinks that this number is perhaps very much exaggerated) annually leaves Macassar for this fishery; it sails in January, during the western monsoon, and coasts from island to island, until it reaches the north-east end of Timor, when it steers south-east and south-south-east, which courses carry them to the coast of Australia; the body of the fleet then steers eastward, leaving here and there a division of 15 or 16 proas, under the command of an inferior raja, who leads the fleet, and is always implicitly obeyed. His proa is the only vessel which is provided with a compass; it also has one or two swivels or small guns, and is perhaps armed with muskets. Their provisions chiefly consist of rice and cocoa-nuts; and their water, which during the westerly monsoon is easily replenished on all parts of the coast, is carried in joints of bamboo. "After having fished along the coast to the eastward until the westerly monsoon breaks up, they return, and by the last day of May each detached fleet leaves the coast, without waiting to collect in one body. On their return they steer north-west, which brings them to some part of Timor, from whence they easily retrace their steps to Macassar, where the Chinese traders meet them, and purchase their cargoes. At this time (1818) the value of the trepang was from forty to fifty dollars a picol; so that if each vessel returns with 100 picols of trepang, her cargo will be worth 5000 dollars. Besides trepang, they trade in sharks' fins and birds' nests, the latter being worth about 3000 dollars the picol." To this Captain King appends a note, stating that in 1822 the value of the trepang was much less, the price having fallen to 25 dollars the picol. In Crawfurd's 'Indian Archipelago' it is stated that the Slug, or Trepang, is sometimes as much as two feet in length and from seven to eight inches in circumference; a span long and two or three inches in girth is however the ordinary size. But quality and value do not depend upon its size, but upon properties not discernible by those who have not had much experience in the trade. In shallow water the animal is taken out by the hand, but in deeper water it is sometimes speared. When taken, it is gutted, dried in the sun, and smoked over a woodfire. The fishery is carried on from the western shores of new Guinea and the southern shores of Australia, to Ceylon inclusive. Indeed within the last few years it has been successfully prosecuted on the shores of the Mauritius. The whole pro-

duce goes to China. In the market of Macassar, the great staple of this fishery, not less than thirty varieties are distinguished, varying in price from 5 Spanish dollars a picol (133⅓ lbs.) to fourteen times that price, each variety being distinguished by well known names. The quantity of trepang sent annually to China from Macassar is about 7000 picols, or 8333 cwt; the price usually varying from 8 dollars a picol to 110 and 115 dollars a picol, according to quality. There is also a considerable export of trepang from Manilla to Canton.—*Eng. Cyc.*

(4356) HOLYHOCKS: ALTHEA ROSEA. VARIETIES.—Well worth cultivating on the plains during the cold months. Seeds should be sown thinly in wooden boxes successively during the rains. When they have formed 3 or 4 leaves they should be planted out in the flower garden. Nothing can excel their gaudy appearance, if planted in well prepared soil, where they will grow from 6 to 12 feet high. Owing to their rapid development, it is a doubtful matter if double flowers will ever be had on the plains. They take about six weeks or two months from the time of sowing to flowering. Native of China. —*Jaffrey.*

(4357) HOMALONEMA AROMATICA. *Syn.* CALLA AROMATICA. Roxb. Fl. Ind. iii. p. 513.

Kuchoo gundubee, BENG.

A native of Chittagong, tubers covered with the dried sheaths of the leaves, with long white fibres proceeding from every part. When cut they exhale an aromatic scent like ginger. As a stimulant it is highly esteemed in India. (*Roxb.*) —*O'Shaughnessy, page* 625. Wight figures also Homalonema Calyptratum, 799; and rubescens, 807.

(4358) HONE. A fine kind of stone obtained from Germany and Turkey, used for sharpening or setting cutlery. It is of a green colour, inclining to yellow, often marked with thin dentrical lines, and is moderately hard, having a fine close texture, resembling indurated clay.—*Waterston.*

(4359) HONEY.

Ussul-ul-nehl, Injubeen, ARAB.	Miele, IT.
Pya-ya, BUR.	Mel, LAT.
Meepanny, CYNG.	Ayer-maddoo, MAL.
Honig, Honing, DUT.	Shahud, PERS.
Miel, FR.	Med, RUS.
Honig, GER.	Madhu, SANS.
Mudh, GUZ.	Miel, SP.
Mudh, Shahud, HIND.	Tayn, TAM.
	Teyni, TEL.

Honey consists essentially of sugar, with variable proportions of gum, wax, and aromatic and colouring principles. It is nutritive and slightly laxitive. The best description of honey procurable in the bazars, is that brought from the Arabian Gulf.—*Faulkner.* It is obtained from Apis mellifica, Linn., Order Hymenoptera, Linn. This is the Honey-Bee which is officinal only on account of the Honey and Wax which it secretes or stores up. Honey is secreted by the nectaries of flowers, sucked by the Bee into its crop, where it undergoes some slight changes, and is then stored up in the comb. The finest honey is that which is allowed to drain from thence; and, if obtained from hives which have never swarmed, it is called Virgin Honey. It partakes of the properties of the plants from which the bees have collected it. When of fine quality it is liquid and viscid, but translucent having a fine, though peculiar odour, and a very sweet taste, but the best appears to some people slightly acrid, from the uneasiness experienced in the fauces. After a time honey becomes thick, white, and granular in texture. Inferior qualities are of a reddish brown colour, granular, and intermixed with impurities, and are usually obtained by pressure of the comb. Honey is soluble in water, and a great part is taken up by boiling Alcohol. It is composed of crystallizable, with some uncrystallizable sugar, a small proportion of Mannite and a little aromatic principle. The inferior qualities contain wax, some acid matter, and impurities. Diluted with water, it undergoes the Vinous fermentation, and Hydromel, or Mead, is produced. "Honey should be clarified by despumation before being used. A watery solution is not rendered blue by Iodide of Potassium added along with an acid," proving that it is not adulterated with Starch. Mel despumatum, M. Clarified Honey, is prepared by melting Honey in the vapour-bath, and then removing, the scum.—*Royle.*

(4360) HONEYSUCKLE: CAPRIFOLIUM. This genus is seldom to be found on the plains of India, in a very satisfactory condition: with few exceptions, they are generally natives of cold countries, requiring rich vegetable soil, grow freely from cuttings under glass, if not kept too damp. —*Jaffrey.*

(4361) HONGE.

Honge, CAN.	Hip-pe, CAN.
Nella Kalavalu, TEL.	Moha, HIN. and MAH.
Karanj, HIND. and MAR.	

Are two different trees grown in the woods of Mysore. Oil is obtained from both of their seeds. The oil of the former is very smoky and bad though clear to look at; but the oil of the latter (Hippay) is just as white and good as the Cocoanut oil. The Hip-pe trees are extensively planted in topes in front of villages, for the purpose of obtaining oil.—*M. E. of* 1857.

(4362) HOOPS. Are circular bindings of casks or barrels, formed of iron, twigs, bamboos, &c.—*Faulkner.*

(4363) HOORMUL. Seed. Lahoorie Hoormul; Harmalæ Semina Seeds of Peganum Har-

mala, gray, small, pyramidal and triangular: small, and are used as rue.—*Ben. Pl.* 297.

(4364) HOPEA DECANDRA, Buch. Ooroopa wood.

Ooroopa, Mal.

Ooroopa is the Malayalum name of a tree which the natives of that country prefer to Teak for building ships, being more durable and close grained.—*Ain's Mat. Med. p.* 207.

(4365) HOPEA ODORATA.

Shingan, Burmese.

This hopea is considered the most valuable indigenous timber tree in the southern provinces of Tenasserim; and at Tavoy and Mergui it is sawn up for building purposes. The best canoes are made of hopea, and it is used extensively in native boat building.—*Mason.*

(4366) HOPEA ODORATA, plentiful in the Tenasserim Forests, is scarce in Pegu, and a few trees are to be found about the vicinity of Rangoon. Light-brown wood.—*McClelland.*

(4367) HOPS.

Hope. Dut.	Humulus, Lupulus, Lat.
Houblon, Fr.	Chanel, Rus.
Hopfen, Ger.	Oblon, Sp.
Luppoli Bruscandoli, It.	

Humulus is a genus of Plants belonging to the natural order *Urticaceæ*. It has the following characters:—Flowers dioecious, Males with the perianth parted; stamens 5; females with the perigone scale-like, open, hidden by the scales of an oval catkin; stigmas 2, elongated. The Hop twines round hedges in many parts of Europe. It is truly wild in England, and is also found apparently wild in the United States of America. It has rough opposite cordate lobed leaves, and numerous greenish-white flowers, of which the sexes are distinct. In the male the flowers form loose drooping panicles, and each consists of 5 sepals, 5 stamens, and a convex centre representing the ovary. In the female the flowers are arranged in little axillary stalked scaly tufts; each consists of a naked ovary, with two spreading downy stigmas, and is inclosed by a concave bract. These bracts increase in size after the flowering is past, are collected into a loose head of imbricated scales, within which are placed the small seed-[illegible], or seeds, as they are usually [illegible]. The [illegible] Koro- [illegible] ority of the Hop, as an ingredi- [illegible] seems [illegible] uors, depends upon the fact of [illegible] near th[illegible]in itself several distinct and in- [illegible] just as [illegible] Hip- [illegible] polony [illegible] ts of activity, which the bitter [illegible] different times been employed [illegible] as a [illegible] vanta[illegible]t possess. The bitter prin- [illegible] pentari[illegible] everage a tonic quality and [illegible] Koro, [illegible] while at the same time an [illegible] ing, wh[illegible]s a warmth and stimulating [illegible] Survey [illegible] modifies the bitterness: it likewise [illegible]ns an astringent principle (tannin), the effects of which are to precipitate the vegetable mucilage, and thus to remove from the beer the active principle of its fermentation: every attempt therefore to substitute an ordinary bitter for that of the Hop must necessarily fail, unless a compound can be so artfully constructed as to contain in due proportions the principles of bitterness, astringency, and aroma. The aromatic bitter gives to the Hop a very marked power over the digestive organs when debilitated. A narcotic property has also been ascribed to this article, which is denied to it by some writers, who attribute the intoxicating power of beer entirely to the alcohol and carbonic acid which it contains. Yet there can be no doubt that tincture of hops, and even extract of hops, possess sedative powers, and often procure quiet and sleep, where opium cannot be borne. Decoction does not seem to be a judicious mode of preparation, and should not be practised. Lupuline has been administered alone, but this does not possess any advantages over the common plan.—*English Cyclopædia.* Two varieties of the Hop plant are particularly distinguished; one cultivated near Canterbury and in East Kent, of which both the plants and catkins are smaller; the latter ovoid, about an inch and a half in length, of a pale but lively yellowish-green colour, and of a fine aromatic fragrance. The West Kent or Sussex Hop grows to a much larger size, is considered hardier, and its catkins are about two and a half, sometimes four inches in length, but do not bring so high a price in the market as the East Kent Hops. As root-sets from the female plants are alone planted by cultivators, the author was led to inquire how the seed was perfected? and if not, whether the Hop glands were produced in as great abundance and perfection as they might be if some *male* were set along with the *female* plants. He is informed by Mr. Alderman Masters of Canterbury that some *male* blossoms are always produced on the female plants, and suffice for the purpose of fertilizing them. Dr. Royle has been unable to learn whether the female ever changes into a male plant, or *vice versa*, as has been observed with the Nutmeg plant. He mentions, that, owing to the kindness of the above gentleman, as well as of Joseph Royle, Esq., of Stuppington, where the finest Hops are grown, he has been enabled to introduce the Hop plant into the Himalayas, where it is now flourishing alongside of the China Tea plant. The root-sets, with the ends dipped in wax, wrapped in cotton, and enveloped in caoutchouc cloth, were sent by the overland mail to the East India Company's Botanic Garden at Sharunpore. They arrived there in a living state, as reported by Dr. Jameson, and have produced fine plants, as well as the seeds sent with them. The successful cultivation of Hops would make malt liquors more within the reach of European soldiers, and assist in detaching them from the perni-

cious spirituous compounds of the bazars, which now destroy the health and shorten the lives of thousands. Well *hopped* ale, moreover, is well known to be one of the best stomachics and tonics for convalescents from many Indian diseases. —*Action. Uses.* Stomachic and Tonic, slightly Narcotic. The property of Hops of giving the bitter to Beer, and, by preventing acetous fermentation, of enabling it to be kept much longer, is well known. To it no doubt is owing a portion of the stomachic properties of malt liquor, as we see exemplified in the bitter, often called Indian, ales. Hops are Hypnotic, especially when stuffed into a pillow, but they should be first moistened with Spirits, to prevent the rustling noise. Fomentations also have been used. Hops are thought to be Diuretic (as is also the root), and to be useful in correcting Lithic acid deposits.—*Royle. Eng. Cyc.*

(4368) HORDEUM, the genus of Plants to which the corn called Barley belongs. It is distinguished from *Triticum*, or the Wheat genus, by its spikelets having only one perfect floret in each, and by its glumes being somewhat unilateral and bearded; Rye, or Secale, differs in having two perfect florets to each spikelet, and in the same additional circumstances as *Triticum*. As many as 15 species of *Hordeum* are distinguished by Professor Kunth, the latest writer upon the subject; in addition to which there are many varieties. The species are found wild in various places in both the Old and New World: as many as eight inhabit America. In the application of their botanical names to the cultivated barleys there is some confusion, one writer distinguishing four species, another six, and some a greater number. It does not appear possible to determine, upon existing evidence, which of these opinions is most correct; the probability however seems to be that there are not more than four, or at the utmost six species, which may be readily distinguished by attention to the following circumstances:—The 1-flowered spikelets of Barley grow in threes, on opposite sides of the ear. If all the spikelets are perfect, the grains of corn are therefore necessarily arranged in six lines or rows; these rows may be very distinctly arranged, as in *H. hexastichum*, or they may be disposed in an irregular manner, as in *H. Ægiceras*. But if the lateral spikelets of each parcel are imperfect all along the ear, the middle spikelet alone producing a grain of corn, the grains in that case will be in two rows only, as in *H. distichum* and *H. Zeocriton*. Of these two distinct forms there are some in which the grain adheres to the paleæ, or husk, as in common Barley, and others in which the grain is free from the husk, as in Naked Barley. It is generally supposed that barleys of the second kind are mere varieties of those of the first kind; but there is no proof of the correctness of the opinion, and probability against it. These characters and a few others being attended to, cultivated barleys may be arranged under the following heads:—Of most of the species there are many varieties, the most striking of which are those called 'Black Barleys,' on account of the dark colour of their husks. They are not of sufficient importance to require particular notice, except in works treating of agriculture in great detail. —*Engl. Cyc.*

(4369) HORDEUM ÆGICERAS (Royle's Manuscripts). Ears cylindrical; florets arranged in a confused manner, not in rows; awns soft, short, hooded, and bent downwards; grains loose in the husk. A most curious species, found in the northern parts of India, and probably in Tartary, as its grains have been sent to England under the name of 'Tartarian Wheat.' Its appearance is more that of wheat than of barley, and its naked grains assist the resemblance. It is however a genuine species of *Hordeum*. It appears to be a productive plant, but little is as yet known of its quality in the climate of England.

(4370) HORDEUM DISTICHUM (Linn., 'Sp. Pl.,' 125). Ear cylindrical; awns almost parallel with the ear; grains adhering to the husk. This is the common Summer-Barley of England, and that which cultivators seem to prefer; its ears are not so large as those of *H. hexastichum*, but the grains are heavier. It is commonly stated to be a native of Tartary. Colonel Chesney found it wild in Mesopotamia, upon the banks of the Euphrates.—*Eng. Cyc.*

(4371) HORDEUM GYMNODISTICHUM (Lowe's 'Elements of Agriculture,' p. 238.) Ear cylindrical; awns almost parallel with the ear; grains loose in the husk. Naked Barley, a species but little cultivated now, is of unknown origin. It is said to have been introduced into England in the year 1768; but it is reported to have preserved its characters unaltered from time immemorial in some parts of Europe.

(4372) HORDEUM HEXASTICHUM (Linn. 'Sp. Pl.' 125), Ears cylindrical; awns very long, rough, and rigid, rather spreading away from the ear; grains adhering to the husk. It does not appear in what way the *H. vulgare* of Linnæus differs from this. Professor Lowe has justly remarked that there is no such thing as a barley with the grains growing in four rows, the circumstance by which Linnæus defined his *H. vulgare*, and that all such appearances are merely imperfect states of *H. hexastichum*. The native country of this species is unknown: it is the Bere, Bigg, or Winter Barley of farmers, and is particularly valuable for ripening quicker than the common Two-Rowed Barley; its grains are however lighter, and it is considered an inferior species to the last. To northern nations with short summers it is however invaluable.—*Eng. Cyc.*

(4373) HORDEUM GYMNO-HEXASTICHUM (Lowe's 'Elements of Agriculture,' p. 238). Ear cylindrical; awns very long, rough, and rigid, rather spreading away from the ear; grains loose in the husk. The origin of this, the Naked Six-Rowed Barley, is unknown. It is extremely productive, and in some parts of Europe it is reckoned the most valuable of all. The French call it, on account of its good qualities, Orge Celeste.—*Eng. Cyc.*

(4374) HORDEUM ZEOCRITON (Linn., 'Sp. Pl.,' 125). Ears conical; awns spreading away from the ear, in a flabelliform manner; grains adhering to the husk. From the spreading direction of the awns, the ears of this barley acquire a much broader figure at the top than at the bottom, on which account it has been called Battledore Barley; it also bears the name of Sprat-Barley. It is little cultivated in England, because of the shortness of its straw; its native country is unknown.

(4375) HORDEUM VULGARE, H. HEXASTICHON.

Jow, Guz. Hind.

Oats, and rye are the staple crops of northern and mountainous Europe and Asia. In England barley is grown principally in the eastern and some of the midland countries, and chiefly for malting. It is most extensively cultivated in the Himalaya and Thibet, replacing in many districts the wheat, and producing an admirable flour. Since the establishment of the studs at Buxar, Ghazepore, &c., oats have been extensively cultivated. It is a winter crop. Although believed to have been indigenous to the countries bordering on the torrid zone, this grain possesses the remarkable flexibility of maturing in favorable seasons and situations on the eastern continent as far north as 70 deg., and flourishes well in lat. 42 deg. south. Along the Atlantic side of the continent of America, its growth is restricted to the tract lying between the 30th and 50th parallels of north latitude, and between 30 and 40 deg. south. Near the westerly coast, its range lies principally between latitude 20 and 62 deg. north. The barley chiefly cultivated in the United States is the two-rowed variety which is generally preferred from the fullness of its grain and its freedom from smut. Barley has never been much imported from that country, as the Americans have been rather consumers than producers. The consumption of barley there in 1850 in the manufacture of malt and spirituous liquors amounted to 3,780,000 bushels, and according to the census returns, the quantity of barley raised was 4,161,504 bushels in 1840, and 5,167,213 bushels in 1850. In England barley is extensively used for malting, distilling, and making beer; large quantities are consumed in Scotland, or carried into England. In Prussia, about 1 and a half million hectolitres of barley are ann ally raised. In the Canary Isles, about 354,0 bushels are annually exported. In Van Diemen Land in 1844, 175,405 bushels of barley we grown on 12,466 acres. The quantity of barl made into malt in the United Kingdom in t year ending 10th October, 1850, was 5,183,6 quarters, of which about four million quarte were used by 8,500 maltsters. The quantity malt charged with duty in the year ending 5 January, 1851, was 636,641 tons; the avera price per quarter, 26s. 2d. Barley is at prese extensively cultivated in the temperate distric and islands of Europe, Asia, Africa and Austr lia. In Spain, Sicily, the Canaries, Azores ar Madeira, two crops are produced in a year. I North America its growth is principally confine to Mexico, the middle, western, and northe States of the Union, and to the British Nort American provinces. The introduction of barle into the American colonies may be traced bac to the period of their settlement. By the ye 1648 it was raised in abundance in Virginia, bu soon after its culture was suffered to decline, i consequence of the more profitable and increase production of tobacco. It has also been sparing ly cultivated in the regions of the middle an northern States for malting and distillation, an has been employed, after being malted, as a sub stitute for rice. Barley, like wheat, has bee cultivated in Syria and Egypt for more tha 3,000 years, and it was not until after the Ro mans adopted the use of wheaten bread, that the fed their stock with this grain. It is evidentl a native of a warm climate, as it is known to b the most productive in a mild season, and wil grow within the tropics at an elevation of 3,00(to 4,000 feet above the level of the sea. It i one of the staple crops of northern and moun tainous Europe and Asia. It is the corn that next to rice, gives the greatest weight of flou per acre, and it may be eaten with no other pre paration than that of boiling. It requires littl or no dressing when it is sent to the mill, having no husk, and consequently produces no bran In this country barley is chiefly used for malting and distilling purposes. In the year 1850, 40,745,050 bushels of malt paid duty, the num ber of maltsters in the United Kingdom being from 8,000 to 9,000. About one and half million quarters of barley were imported in 1849, and a little over a million quarters in 1850, principally from Denmark and Prussia. The counties in England where this grain is chiefly cultivated are Norfolk, Suffolk, Cambridge, Bedford, Herts, Leicester, and Nottingham. The produce of barley on land well prepared, is from thirty to fifty bushels or more per statute acre, weighing from 45 to 55 lbs. per bushel, according to quality. It is said to contain 65 per cent. of nutritive matter, while wheat contains 78 per cent. The

estimated average produce of barley in this country may be stated as follows:—

	Acres.	Crop.
England,.....	1,500,000	 6,375,000
Ireland,.....	320,000	 1,120,000
Scotland,.....	450,000	 1,800,000
	2,270,000	9,295,000

The average produce per acre, in the United Kingdom, is 4¼ quarters in England, 3½ in Ireland, and 4 in Scotland. The prices of barley per quarter have ranged, in England, from 36s. 5d in 1840, to 27s. 6d. in 1842. In 1847 barley reached 44s. 2d., and gradually declined to 23s. 5d. in 1850.—*Simmonds' Comm. Prod. p.* 256.

(4376) HOREHOUND WHITE, PATCH LEAVES.

Pucha Pat, BENG. | Marrubium Indicum, LAT.
Patch Putta, GUZ. HIND.

These leaves are of a whitish-gray colour, having a woolly appearance, and possessing a faint agreeable odour, and a sharp bitter taste. That met with in Bombay, is imported from Singapore and is used in various ways by the natives, but chiefly as an ingredient in Gooracoo, and when combined with other herbs, for scenting the hair of women. The essential oil is in great request for imparting the peculiar fragrance of the leaf to clothes among the superior classes of the natives.—*Faulkner.*

(4377) HORN.

Hoorn, DUT. | Cornu, LAT.
Corne, FR. | Sing, GUZ. HIND.
Horn, GER.

Horn is distinguished from bone by being soft, tough, semi-transparent, and susceptible of being cut and pressed into a variety of forms. They are extensively used in the manufacture of handles for knives, walking sticks, and in that of spoons, combs, lanthorns, snuff-boxes, powder flasks, &c. Glue is sometimes made of the refuse of horns. Buffaloe and Deer horns are largely exported from Bombay to England; and Cow and Rhinoceros horns occasionally in small quantities.—*Faulkner.* Horns and Bones of various animals are brought to China in junks from the adjacent countries and islands, and form an important article of import with the native vessels. Buffaloes' horns are worked into lanterns, some of which are highly elegant; the manufacture of small boxes in which to put opium to carry it about the person, annually consumes many hundred pecals. Handles, buttons, and other useful articles, are also made; and the bones are burned into lime. In a single year, 502 peculs have been brought to Canton.—*Morrison.*

(4378) HORNS RHINOCEROS. The best sort comes from Cochin China, and sell at times for $300 a piece; an inferior sort comes from India, of which some probably are from southern Africa, which are sold for $30 and upwards a piece. The Chinese work the finest pieces into elegant cups and other articles, but the most of the importation is used as a medicine; it also forms an article of commerce in the Chinese junks trading to Japan. *Brass Leaf*, or *tinsel*, is manufactured by the Chinese to an enormous extent for making the *kin hwa* or 'golden flowers,' used in worship. It is exported to India; in boxes estimated to hold 50 catties. Also *tin-foil* to a small amount. —*Morrison, page* 143.

(4379) HORNS AND ANTLERS, are exported from Madras, No. 919839, cwt. 2189, Rs. 1,00,218. These are the dense Antlers of the "Samber" (Cervus hippelephas,) of the "barking deer" (Cervus muntjac,) of the "Axis" (Cervus axis,) the Neilghai (Damalis Rusa) and other species of Indian Deer—also horns of the Indian Buffalo, Ox, and Antelope. Horns are procurable all over India. Those for the Madras export market chiefly from Hydrabad in the Dekhan and are exported to the United Kingdom, France, Bengal, Bombay, and Ceylon. Ivory, buffalo and deer horn, porcupine quill, &c., such as chess boards, work and knitting boxes, tea-chests and tea-caddies, ink stands, baskets &c., which are lined with sandal-wood, and generally very neatly got up are made at Vizagapatam. But samples sent home to a well known establishment in London, were not considered suited to the English market. They are indeed far surpassed, both in cheapness and workmanship, by articles of a similar description, the produce of German industry, which are largly exported to England. The following are selling prices.

	Rs.	A.	P.
Ivory backgamon board, ...	85	0	0
Do. fluted envelope case, ...	25	0	0
Do. knitting box, ...	12	0	0
Sandalwood and ivory box, ...	8	0	0
Porcupine quill do., ...	8	0	0
White elk-horn inkstand, ...	12	0	0
Black do. do., ...	18	0	0
Porcupine quill, ivory and buffalo horn work box, ...	35	0	0
White elk-horn do., ...	30	0	0
Buffalo horn do., ...	18	0	0
Do. do. tea chest, ...	13	0	0
Sandalwood and ivory basket,... ...	18	0	0
Porcupine quill basket,...	5	0	0

(4380) HORNBEAM. An indigenous British tree (*Carpinus Betulus*) common in copses. In appearance it is graceful, resembling the beech. Its wood is tough, and well suited for toolhandles, cogs, and for other purposes in which strength is required, but it is coarse, and unfit for cabinet work.—*Waterston. Faulkner.*

(4381) HORNBILLS, a family of Birds named after the genus Buceros, Buceridae. They constitute a family of birds, the construction of whose

bills arrests the attention at first sight, and ornithologists have not been entirely agreed as to the situation which the form ought to occupy in the series.—*Eng. Cyc. Vol.* III, *p.* 123. *B. Rhinoceros*, Rhinoceros Hornbill. This species is to be found in most collections, and though there may be some variety from age and circumstance, the bill will be generally found to be about 10 inches long and of a yellowish-white, the upper mandible red at the base, the lower black. The horn, or casque, varied with black and white. The body black, of a dirty white below and posteriorly; tail about 12 inches, the feathers white at the base and tip, black in the middle; feet and claws obscure gray. It is a native of India and the Indian Islands (Sunda, for instance). *B. cavatus*: Throat, ear-coverts, circle round the eye, and a narrow-band at the occipital edge of the protuberance of the beak, black; neck dirty straw-colour, the feathers of the back of the neck elongated; body and wings black, greater coverts and quill-feathers tipped with white; thighs, upper and under tail-coverts, white; so is the tail also, with the exception of a broad black band about three inches from the tip; beak yellowish, inclining to scarlet at the tip, under mandible black at the base; tarsi black. (Gould.) The food of the *Buceros cavatus*, like that of other Hornbills, consists of fruits, berries, flesh, and even carrion; in short, it may be considered as strictly omnivorous. (*Gould.*) It is a native of India, the Himalaya Mountains. Java, and most of the Islands of the Archipelago.—*Eng. Cyc. Vol.* III, *page* 139.

(4382) HORRE. A hard, though coarse, open-grained, heavy Ceylon wood.

(4383) HORSE. The horse has been immemorially domesticated by most of the more advanced nations of the Malay Archipelago, wherever it could be made use of. The chief exceptions are the Malay peninsula, the eastern seaboard of Sumatra, and nearly the whole of Borneo; countries in which the people dwell on the marshy banks of rivers, in which there is not even a bridle-path, and fit, therefore, only for the boat and the buffalo. The native horse is always a mere pony, seldom reaching 13 hands high, and more generally of about 12 hands. There are many different breeds, every island having at least one peculiar to itself, and the large islands, several. Beginning with Sumatra, we have here at least two distinct races,—the Achin and Batubara, both small and spirited, but better adapted to draught than the saddle. Of all the countries of the Archipelago, Java is that in which the horse most abounds, and here we find several different breeds, as those of the hill countries, and those of the plains. Generally, the Java horse is larger than that of Sumatra, but in the language of the turf has less blood and bottom. The lowland horses, the great majority, are somewhat coarse and sluggish, but the upland spirited, smaller, and handsomer. The horse, although of a very inferior breed, is found in the islands of Bali and Lomboc, but the next island to these eastward, Sumbawa, produces the handsomest breeds of the whole Archipelago. They are the Arab of the Archipelago, yet the blood is not the same as the Arab, for the small horse of Sumbawa, although very handsome, wants the fine coat and the blood head of the Arabian. There are in this island, and adjacent islets, three different races, that of Tambora, of Bima, and of Gunung-api, the last being most esteemed. Next to Java, horses are most abundant in Celebes. These are inferior in beauty to those of Sumbawa, but excel all others of the Malayan portion of the Archipelago, in combining the qualities of size, strength, speed, and bottom. A very good breed is produced in Sumba, called in our maps Sandalwood Island. But perhaps the best breed of the whole Archipelago, although still but a pony, is that of the Philippines. It is superior in size to any of the breeds of the western islands, which it may owe to the superior pastures of the Philippines, and, possibly, to a small admixture of the Spanish horses of America, although this last is, by no means, an ascertained point. Generally, the horses of the Archipelago are hardy, surefooted, and docile. The horses are all entire, and the mares used only to breed and as beasts of burden. By the natives of the Archipelago the horse is only used for the saddle or to carry burdens, and never for draught, either for plough, or wheel-carriage. To see horses drawing a native carriage, except in imitation of Europeans, we must go to the sculptures on ancient temples in Java, where they are thus represented. In two islands only of the Archipelago is the horse found in the wild state, Celebes and Luzon, the only ones that are known to have extensive grassy plains fit for its pasture, and in these it is caught by the lasso and broke in as in the Llanos of America. In such situations it is certainly far more likely to have become wild from the domestic state than to be indigenous. In so far as Celebes is concerned this view is rendered probable by the name being a corruption to the Javanese in one language of that island, the Wugi, while in another, the Macassar, the horse is called "the buffalo of Java." In the Philippines it is not even alleged that the wild horses are anything else than domesticated ones become so. In Pigafetta's enumeration of the domestic animals of Cebu, he makes no mention of the horse. In the city of Manilla a pair of good riding horses costs from 100 to 120 dollars, and a pair of carriage horses from 20 to 30. Of course they are much cheaper in the provinces where they are reared. The horses of Sambawa, Celebes and Sumba, are largely exported to Java, to the British settlements in the Straits of Malacca, and

even as far as the Mauritius. In Batavia a good Bima or Batak horse is worth from 10*l.* to 15*l.* —*Crawfurd Dictionary, page* 155. The horse commonly seen in China is a mere pony, not much larger than the Shetland pony: it is bony and strong, but kept with little care and presents a worse appearance than it would if its hair were trimmed, its fetlocks shorn, and its tail untied. This custom of knotting the tail is an ancient practice, and the sculptures at Persepolis show that the same fashion prevailed among the Persians. The Chinese language possess a great variety of terms to designate the horse; the difference of age, sex, color and disposition are all denoted by particular characters.—*Williams' Middle Kingdom, page* 253. The Tanghan, of Thibet are wonderfully strong and enduring; they are never shod, and the hoof often cracks, and they become pigeon-toed: they are frequently blind of one eye, when they are called "Zemik" (blind ones), but this is thought no great defect. They average 5*l.* to 10*l.* for a good animal in Tibet; and the best fetch 40*l.* to 50*l.* in the plains of India, where they become acclimated and thrive well. Giantchi (Jhansi-jeung of Turner) is the best mart for them in this part of Tibet, where some breeds fetch very high prices. The Tibetans give the foals of value messes of pig's blood and raw liver, which they devour greedily, and it is said to strengthen them wonderfully; the custom is, I believe, general in central Asia. Humboldt (Pers. Nar. iv. p. 320) describes the horses of Caraccas as occasionally eating salt meat.—*Hooker, Him. Jour. Vol.* II. *p.* 131. The Thibetan pony, though born and bred 10,000 to 14,000 feet above the Sea, is one of the most active and useful animals in the plains of Bengal, powerful and hardy and when well trained early, docile, although by nature vicious and obstinate.—*Hooker, Vol.* 1. *p.* 118.

(4384) HORSE RADISH, Europe.

Cran de Bretange, Fr. | Raphanus-rusticanus, Lat.

The pungent root of the *Cochlearia armoracia*, a perennial plant common in moist places. It is used as a condiment, and is besides an article of the materia medica. *Waterston.—Faulkner.*

(4385) HORSE RADISH TREE. Moringa Pterygosperma. Hyperanthera Moringa.

(4386) HORSE RADISH, Indian.

Hubul-ban (seeds), Arab.	Moriaben, Pers.
Sujna, Beng.	Sigroomalla, Sobhanjum, Sans.
Sohunjana, Duk.	
Moonga-ka-jar kajar, Sujna, Hind.	Sagut-ka-jhar-kejur, Hind.
	Moorunghy Vayr, Tam.

The root of a tree (*Hyperanthera Moringa*, vern, *Sagul*), commonly cultivated all over India for its leaves, flowers, and pods, which are used in curries, and served up as vegetables. The roots have precisely the same flavour as the English horse radish, for which they are not unfrequently substituted, and seem identical in chemical composition. The long pods, when boiled and used as a vegetable, have much the flavour and taste of asparagus.—*Faulkner.*

(4387) HOYA VIRIDIFLORA, is one of a genus of plants belonging to the natural order *Asclepiadaceæ*, the species of which occurring in Southern Asia, are:—Hoya carnosa, fusca, lanceolata, linearis, ovalifolia, pallida, parasitica, pottsii, pauciflora, pendula, and viridiflora. This last species is a native of Coromandel, Sylhet and the Nilgherry hills. The root and tender stalks produce nausea and promote expectoration. The leaves peeled and dipped in oil are used by the natives of India as a discutient in the early stages of boils and in the more advanced stages to promote suppuration. Several of the species, under the name of Wax plants, are cultivated in England on account of their elegant flowers.—*Voight. Wight. Eng. Cyc.*

(4388) HUBB-OOL-MOOSHK,

Mushkdana, Hind. | Callee Dustooree, Beng.

or musk seeds, so named on account of their odour. Hubool mooshk, (formerly Hibiscus Abelmoschus,) now Abelmoschus moschatus. The plant abounds in mucilage, which is employed in the West Indies and in North Western India in the process of clarifying sugar. Its seeds are scented as if with musk hence their name, and are employed in India as a cordial Medicine and in Arabia are added to coffee.

(4389) HULDEE. Turmeric.

Curcuma Longa, Hind

There are four species of this plant, one a small and very fine sort; the other longer and coarse; the third, the Ambie, used chiefly as medicine, the fourth a wild species. That which is cultivated for domestic culinary purposes is sown in beds like ginger, and when ripe in twelve months taken up and dried. It is extensively cultivated in most parts of India, and sells, green, from eight to eighteen seers the rupee.

(4390) HULEEM. Arabis Chinensis; Cress.

(4391) HUMEA ELEGANS. Compositæ. This plant is a native of New South Wales, grows to the height of five or six feet, colour of the flower red, and well adapted for borders: it requires a good soil.—*Riddell.*

(4392) HURA, a genus of Plants belonging to the natural order *Euphorbiaceæ*. It has monœcious amentaceous flowers; the male flowers have a truncate calyx; numerous stamens united into a solid column; female flowers with 1 style; stigma with 12 or 18 rays; capsule with 12 or 18 cocci.—*Eng. Cyc.*

(4393) HURA CREPITANS. Euphorbiaceæ. The Sand-box tree; a small armed tree of rapid growth. The fruit resembles a small orange without the peel, and when ripe, its

numerous valves burst with an elastic jerk. The *H. crepitans*, or Sandbox-Tree, is a native of the West India Islands, Mexico, and Guyana. It is a tree abounding in milky juice. Leaves cordate, acuminate, entire, or very slightly toothed, stalked, smooth, coriaceous, with simple veins passing from the midrib to the margin in a curved direction, within a quarter of an inch or so of each other, and connected by numerous oblique veinlets; stipules large, ovate, leafy, deciduous; petioles as long or rather longer than the leaves, with 2 glands at the apex. Male flowers arranged in an erect long-stalked axilliary conical catkin, composed of imbricated 1-flowered scales; calyx short, urceolate, truncate; column of stamens surrounded in the middle by 2 or 3 rows of tubercles, each of which bears an anther on its under side. Female flower solitary at the base of the male peduncle, or near it; calyx urceolate, entire, or dividing eventually into 3 parts; stigma very large, discoidal, peltate. Fruit a depressed umbilicated woody capsule, about the size of a middling apple, with from 12 to 18 furrows, which separate into as many cocci, which fly asunder, each opening into two valves with great elasticity when dry and fully ripe. The milk is so venomous as to produce blindness in a few days after touching the eye. Seeds a violent drastic dangerous purgative. Aublet states that negro slaves to whom one or two seeds had been administered in the form of an emulsion, were nearly killed by them. —*Eng. Cyc.*

(4394) HURALA, Can. There are four sorts of the seed, grown in Mysore, viz. Maraharatta, Chitta Haralu, Dod-da Haralu, and Turaka Haralu. They are called in English, Lamp oil seeds. The second and third are largely exported to the adjacent countries.—*M. E. of* 1857.

(4395) HURRIA, Daudin's name for certain Indian Colubers, the scales or plates on the base of whose tails are constantly simple, and those of the point double.—*Eng. Cyc.*

(4396) HURRICANES. These hurricanes at the season of their occurrence (from December to April) form the great topic of interest and discussion in the Mauritius: in fact they talk of little else at that period. The immediate cause of these atmospherical phenomena has been supposed to be a disturbance of the equilibrium in the air that takes places at the change of the monsoons. This period of strife lasts about a month and then the hurricanes rage with terrific violence. Bedfield, Read and others have explained the laws by which they suppose them to be governed and their hypothesis is perfectly well known and understood by the Mauritians. The islands of Mauritius, Bourbon and Roderique lie directly in their ordinary track and if either of them happens to fall within the vortex of one of these hurricanes the consequences to life and property are terrible indeed. Of those residing at Mauritius who have earnestly studied and discussed the laws which govern these storms may be mentioned Dr. Thom, whose writings are well known, Lieutenant, Fryers of the royal engineers, and Mr. Sedgewick, who has published a little work, which he calls "The True Principle," and which has been reviewed by Dr. Thom, and, lastly, a gentleman attached to the observatory at Mauritius, Mr. Bosquett. This last named gentleman who has translated into French Piddington's Horn book with annotations of his own, claims to be able, by careful and constant meteorological observations, to foretell the existence of hurricanes in the Indian ocean and to describe the course they will take. The day before the Mississippi left Mauritius, he informed the Commodore that a cyclone was then blowing in a direction E. by N. from the island and that it would pass to the southward and eastward. By reference to the chart in Piddington's Horn book, it will be seen that these cyclones never extend to the northward of 10° or 12° south latitude in the meridian of Mauritius. Therefore vessels leaving the island in the hurricane season, for any part of India, should steer to the northward passing well to the westward of the Cargades, a most dangerous group, thus keeping a clear sea open to the westward, that there may be nothing in the way should it be desirable to run to the northward and westward, which would be the true course to take in case of encountering the southwestern or northwestern quadrants of a cyclone (which in the hurricane season a vessel from Mauritius is in danger of,) and this course she should keep until she is sufficiently far north to be beyond its influence. Steamers of course have superior means of avoiding these storms as they have the power of steering the most judicious course to escape from their greatest fury.—*American Expedition to Japan, p.* 137.

(4397) HURTAL, Persulphuret of Arsenic: Orpiment. There are two kinds, viz. Gobheri hurtal, in yellow flakes, used in oil painting, one seer costs one rupee four annas. Tabki hurtal, greenish crystallized: given by fakeers in fumigation: one ruttee of it is wrapped up in a leaf of "Muggarbel," and smoked in a hookah: it is evident that the smoker only escapes dangerous consequences, owing to the heat volatilizing most of the arsenic: as it is, the little inhaled often makes the person senseless, salt is then given to restore the senses: thus employed, tabki hurtal is considered a most powerful aphrodisiac, it is also used in ointments: costs three rupees for one seer.—*Genl. Med. Top.* p. 137.

(4398) HYACINTH, a Mineral, consisting of silica and zirconia, transparent, and of a red colour.

(4399) HYACINTHUS, a genus of Plants belonging to the natural order *Liliaceæ* and the

tribe *Scillceæ*. One of the most common of four garden plants is the *H. orientalis*. The genus formerly included two species of British plants, which are now referred to the genera *Endymion* and *Muscari*.—*Eng. Cyc.*

(4400) HYACINTHUS ORIENTALIS. These well known plants in Europe, are much esteemed for their beautiful and ornamental appearance, they are grown both in beds and glasses of water, the H. Orientalis is one of the most beautiful and fragrant : native name Sambul ; bulbs of different species are easily procurable from China. —*Riddell.*

(4401) HYÆNINA, the name of a family of Digitigrade Carnivorous *Mammalia*, distinguished by having their fore legs longer than their hind legs, by their rough tongue, great and conical molar, or rather cutting-and-crushing teeth, projecting eyes, large ears, and a deep and grandular pouch beneath the anus.

Dental Formula:—Incisors, $\frac{6}{6}$; canines, $\frac{1\text{-}1}{1\text{-}1}$; molars, $\frac{5\text{-}5}{4\text{-}4}$=34.

The false molars, three above and four below, are conical, blunt, and very large. The upper flesh-tooth (carnassiere) has a small tubercle within and in front, but the lower one has none, and presents only two trenchant points. The whole of the dental and molar organisation, and indeed the whole cranial structure, appears to have been formed with a view to the bringing into the most available action the formidable natural instruments which enable the Hyænas to break the hardest bones.

(4402) HYDNOCARPUS. The "Took" one of this genus grows in the Teesta valley in Sikkim. It is a beautiful evergreen tree, with tufts of yellow blossoms on the trunk : its fruit is as large as an orange, and is used to poison fish, while from the seeds an oil is expressed.—*Hooker Him. Journal Vol.* II. *page* 7.

(4403) HYDNOCARPUS INEBRIANS. *Flacourtianeæ*. Icon. 942.

Marravuttay marum, TAM.

A large tree, little is known of the wood, the berry is used for poisoning fish. Wight No. 51, Tinnevelly, Travancore 37. A common tree on the west coast, not so in the Coimbatore jungles. The quality of the wood is unknown.—*Wight.*

(4404) HYDNOCARPUS VENENATA, of Ceylon, allied to this order, has poisonous fruit, and induces intoxication.

(4405) HYDRANGEACEÆ, *Hydrangeads*, a natural order of Exogenous Plants consisting of shrubs, with perfectly opposite simple leaves, smooth or downy, with simple hairs, destitute of stipules, sometimes, creeping and rooting like ivy. Flowers usually in cymes ; those in the centre male, the marginal often sterile, and furnished with larger petals than the others. Calyx adhering more or less to the ovary, 4- or 6-toothed. Petals 4 or 6, inserted within the edge of the calyx, deciduous. Stamens 8 or 12, in two rows, inserted in the orifice of the calyx, distinct, deciduous. Anthers oblong or roundish, pollen with three longitudinal furrows. Ovary more or less adherent to the calyx, consisting of from 2 to 5 carpels, adhering by their sides, and forming an incompletely 2-or 5-celled cavity ; placentæ distinct from each other, but touching with many anatropal ascending or horizontal ovules ; styles as many as the carpels, perfectly distinct, diverging, with simple reniform stigmas. Fruit a capsule crowned by the permanent diverging styles, 2- or 5-celled, with a number of minute seeds, sometimes indefinite sometimes few, in consequence of the abortion of a part of the ovules. Testa thin, membranous, netted, occasionally expanded into a wing. Embryo orthotropal in the axis of a small quantity of fleshy albumen. The relationship between Hydrangeads and Saxifrages is admitted by all systematists, who have in general united them in the same order. Lindley places this order between *Saxifragaceæ* and *Cunoniaceæ*, and near *Philadelphaceæ* and *Caprifoliaceæ*. It differs from *Hensloviaceæ* mainly in its indefinite seeds, small quantity of albumen, and constant tendency to produce a superior ovary. Out of the species hitherto discovered, all of which inhabit the temperate parts of Asia and America, two only belong to the southern hemisphere, and twenty-three or about one-half to China and Japan. The species are found naturally in moist shady places. None of them appear to be of much use to man.

(4406) HYDRANGEA, is a well-known genus of hardy shrubs, of which one species is commonly cultivated for the sake of its beautiful flowers. This plant is a native of China and Japan : it was originally observed in the gardens of Canton by Loureiro, who took it for a primrose, and called it *Primula mutabilis*. It was next met with by Commerson, a French traveller, who named it *Hortensia*, in compliment to Madame Hortense Lepleaute.

(4307) HYDRASTIS CANADENSIS, or Canadian yellow root, a valuable bitter tonic, and useful yellow dye-stuff.

(4408) HYDRIDÆ. These are the true Sea-Snakes. They coil themselves up on the shore, and appear to live on sea-weed, and lay their eggs on the shore. They are often found asleep on the surface of the sea, where they are easily caught, for they cannot descend into the sea without throwing themselves on to their backs. This arises apparently from the necessity of expelling the air from their large lungs. They are often thrown ashore in the surf, and are occasionally carried up rivers by the tide, but they cannot live in fresh water. Their bite is venomous, and they are held in

great dread by fishermen wherever they occur, on this account. In spite of their venomous properties, one species at least, the *Hydrus Pelamis*) *bicolor* is said by Cuvier to be eaten at Taheite.

Pelamis. P. bicolor. Pacific Ocean. *P. ornata* Borneo.—Head moderate, rather compressed; gape moderate.

Lapemis.—Head moderate, short, rounded in front; dorsal scales square; ventral shield broad, 6-sided. *L. curtus.* Madras. *L. Hardwickii.* Borneo.

Aturia.—Head moderate, short, rounded in front; dorsal scales 6-sided; ventral shield 6-sided. *A. ornata.* Indian Seas. *A. Belcheri.* New Guinea.

Microcephalophis.—Head small; scales 6-sided; ventral scales keeled. *M. gracilis*, the Kadel Nagam. Madras. Scales ovate, 6-sided, imbricate, keeled, or with the keel reduced to a tubercle on the centre of the scales; head and gape moderate. Labial shields occupying the greater part of the lips; the eyes over the fourth, or rarely over the third or the fourth or fifth shield; ventral shield united.

Enhydrina.—Rostral plates narrow, erect; lower linear, sunken; nasal narrowed in front; ventral shield flat; head moderate, short; eyes moderate.

E. Bengalensis. Madras.

E. Valakadyen. Madras.

Hydrophis.—Rostral broad, transverse; lower triangular; nasal truncated or notched in front; ventral shield flat; head short; eyes small.

H. obscura, the Shooter Sun. Madras.

H. Lindsayii. China.

H. fasciata. Indian Ocean.

H. nigrocincta, the Kerril. Bengal.

H. doliata, the Black-Headed Kerril. Australia.

H. subcincta, Shaw's Chittul. Indian Ocean.

H. sublœvis, the Chittul. China and Indian Ocean.

H. mentalis, the Pale Chittul. Indian Ocean.

H. ocellata, the Eyed Chittul. Australian Seas.

H. spiralis, the Shiddil. Indian Ocean.

H. subannulata, the Ringed Sea-Snake. India.

H. aspera, the Rough Sea Snake. Singapore.

H. cærulescens, the Bluish Sea-Snake. Bengal.

Chitulia.—Rostral broad, transverse; lower triangular; nasal truncated or notched in front; ventral shields flat; head elongate, depressed; eyes large.

C. inornata. Indian Ocean.

C. fasciata. Indian Ocean.

Kerilia.—Rostral broad, transverse; lower triangular; nasal truncated in front; ventral shield broad, convex, forming a slight kneeled ridge; the hinder ones with a keel on each side; head short, shelving; scales very large, broad, 6-sided; eyes rather large, over third and fourth labial shields.

K. Jerdonii, the Karilia. Madras. Labial shield occupying the front half of the lip; eyes over the fifth or sixth shield; hinder part of the face covered with small scales; ventral scales generally 2-rowed, forming a keeled ridge, some united in pairs into 6-sided shield.

Hydrus.

H. major, the Sea-Snake. India; Australia.

H. annulatus, the Ringed Sea-Snake. Singapore.

Body covered with smooth polished imbricate scales; head as large as the body; ventral shields rather large, transverse, smooth, folded together and keeled.

Tomogaster.—Head with regular shields; superciliary shields simple; ventral shields entire.

T. Eydouxii. Indian Ocean.

Stephanohydra.—Head shields numerous; superciliary shields 3 or 4; ventral shields nicked behind.

S. fusca, Jukes's Hypotrophis. Darnley Islands. Head covered with scales, like the body; nostrils surrounded by a small, continuous ring; eyes surrounded by a series of small scales; labial shields small, with a larger series above them; pupil round; ventral shields very small scale-like, separated on each side of a keeled ridge. The species are all inhabitants of rivers.

Acrochordina.

Chersydrus.—Tail compressed, sword-shaped, prehensile; body fusiform, covered with small rhombic scales, with a central tubercular keel.

C. annulatus. Madras.

C. granulatus, the Chersydrus. Madras.

Acrochordus.—Tail conical, tapering, moderate; body fusiform, covered with tricuspid scales.

A. Javanicus. Java. Tail conical, tapering. Belly rounded beneath, with more or less broad band-like shields. Rivers or ponds. Head shielded; tail scaly beneath; abdominal shields flat, small, 6-sided, with a keel on each side, as if formed of two united scales; nostrils in a ring of small scales; scales keeled.

Erpetonina. Erpeton.

E. tentaculus, the Erpeton.

Cerberus.—Scales keeled, striated; hinder labial shield low. *C. cinereus*, the Karoo Bokadam. India. *C. acutus.* Borneo. *C. unicolor.* Philippines *C. australis.* Australia.

Homalopsis.—Scales keeled. *H. buccata.* Java. *H. Hardwickii.* India.

Phytolopsis.—Scales smooth.

P. punctata. India.

Tropidophis—Scales ovate, keeled, striated; eye over fourth and fifth shield.

T. histosus, the Chittee. Ceylon.

Myron.—Scales ovate, slightly keeled, smooth. *M. Richardsonii.* Australia. *M. trivittatus.* India.

Hypsirhina.—Seventh labial large; eye over the fourth and fifth labial; loreal distinct. *H. plumbea.* Borneo. *H. Hardwickii.* Penang. *H.*

Aer, the Ular Aer. Borneo. *H. bilineata*. China. *H. Chinensis*. China. *H. Bennettii*. China.

Fordonia.—Scales broad, rhombic; ventral shield rounded; loreal none; eye over third labial. *F. leucobalia*. Timor. *F. unicolor*. Borneo.

Raclitia.—Head small, conical; body subcylindrical; anterior frontal very small, triangular; loreal distinct; posterior ocular.

R. Indica India.

Miralia.—Head small, conical; body compressed; frontal plates 2 pairs; loreal none; posterior ocular 2.

M alternans. Java.

Xenodermus.

X. Javanicus, the Gonionote. Java. "The distribution of the colours on the body appears to be one of the most permanent characters of the species; but this becomes less distinct in the older specimens, and is often lost in the specimens that have been carelessly or long preserved in a museum.' The existence of this family of water-Snakes has undoubtedly given rise to the notion that a large Ophidian, which meets the popular view of a Great Sea-Serpent, exists. In all cases however, the reports of the existence of such a creature have been traced to the capture or sight of some other animal, or to the exaggerated representations of some other natural object. The *Hydridæ* amongst the *Ophidia* are of comparatively small size, seldom equalling the *Boidæ* in this respect, and falling far short of the enormous dimensions popularly attributed to the Great Sea-Serpent.—*Eng. Cyc.*

(4409) HYDROCHARIDACEÆ, *Hydrocharads*, a small natural order of Endogenous Plants inhabiting ditches, lakes, and rivers in various parts of the world. They have tripetaloideous flowers, often separate sexes, and an inferior ovary. The latter character cuts them off from *Alismaceæ* and *Butomaceæ*, to which they bear some resemblance in habit. *Vallisneria spiralis*, a plant of this order, is remarkable for its spiral flower-stalk, which enables it to accommodate itself to the depth of the stream in which it floats, so as always to keep its flowers above water when it is necessary. It is in the leaves of this plant that a peculiar movement in the interior of the cell called *Cyclosis* was originally observed. The same movement is also seen in the cells of *Hydrocharis Morsus Ranæ* and *Anacharis alsinastrum*, and is probably present in the whole of the order. The species are natives of fresh-water in Europe, North America, and the East Indies. One species is found in Egypt (*Damosonium Indicum*), and two Vallisnerias in Australia. Nothing is known of their uses unless that the fruit of *Enhalus* is eatable, and its fibres capable of being woven. According to Agardh, *Ottelia* and *Boottia* are eaten in India as pot-herbs. The Janji of Hindustan, the *Vallisneria alternifolia* of Roxburgh *Hydrilla* of Hamilton, is one of the plants used in India for supplying water mechanically to sugar in the process of refining it, "as clay is used in the West Indies to permit the slow percolation of water." Lindley places this order near *Naiadaceæ*, *Pistiaceæ*, and *Bromeliaceæ*. It has 12 genera and 20 species.

(4410) HYDROCOTYLE (from ὕδωρ, water, and κοτύλη, a cavity), a genus of Plants belonging to the natural order *Umbelliferæ* and to the suborder *Orthospermeæ*. The calyx obsolete; the petals ovate, entire, acute, with a straight apex; the fruit flatly compressed from the sides; the carpels without vittæ; the five ribs or nerves nearly filiform, the carinal and lateral ones usually obsolete, and the two intermediate ones joined. The species of this genus are generally bog-herbs; but few of them are under-shrubs. The umbel is single, surrounded by a few-leaved involucrum; the flowers sessile or pedicillate, white. Upwards of ninety species of plants have been referred to this genus. It is not however improbable that a more attentive study of them will lead to the distinction of other genera amongst them. Of the large number of species of this genus few if any are used in the arts or medicine, and none of them are sufficiently ornamental to lead to their cultivation. *H. Asiatica* is said to be used in India as a diuretic, and occasionally as a culinary vegetable. *H. umbellata* is recommended by Martius as a remedy in hypochondriasis, but on what grounds is not stated. The fresh juice acts as an emetic. It is said to possess an aromatic odour and an agreeable taste. The species of *Hydrocotyle* are easily cultivated; they must all be kept moist. The stove-greenhouse and frame kinds should be grown in pots placed in pans of water. (Don, *Dichlamydeous Plants*; Burnett, *Outlines*; Babington, *Manual of British Botany*.)

(4411) HYDROCOTYLE ASIATICA. UMBELLIFERÆ. Lin.

Vullarei keeray, TAM. | Mundooka purnie, SANS.
Mundooka brummie, TEL.

This is the greens of a plant of the class Pentandria and order Digynia.—*Ainslie's Mat. Med. p.* 258. An herbaceous plant, grows in moist shady places, flowers green, and of an uninteresting nature. An infusion of the toasted leaves of this low growing plant, in conjunction with Vendeum is given to children in Fever cases. This appears to be the Codagen of the Hort. Mal. Part 10, page 46.—*Ainslie's Mat. Med. p.* 126.

(4412) HYDROLEA ZEYLANICA. Vahl. Wight and Arnott in Hooker's Comp. 2. t. 26. Grows in water and marshy ground in East Indies, Herbaceous. The leaves beaten into a pulp and applied as a poultice are in India deemed useful in cleaning and healing ill conditioned ulcers in which maggots have formed. Lind. Fl. Med. p. 401.—*O'Shaughnessy, page* 507.

(4413) HYDROPHYLLACEÆ, *Hydrophyls*

a natural order of Exogenous Plants, consisting of small trees, bushes, or herbaceous plants, often hispid. The leaves are often lobed, alternate, or the lower ones opposite. The flowers arranged in gyrate racemes or unilateral spikes, or occasionally solitary and stalked in the axils of the leaves. Calyx inferior, persistent, deeply 5-cleft the recesses usually augmented with reflexed appendages. Corolla monopetalous, hypogynous, regular, shortly 5-cleft, between campanulate and rotate, rarely funnel-shaped. Stamens 5, epipetalous, alternate with the segments of the corolla, inflected in æstivation; anthers versatile, 2-celled, the cells parallel, dehiscing longitudinally. Ovary superior, simple, 1- or 2-celled, styles 2, long; stigmas 2, terminal; placentæ 2, free at their back, or united to the shell of the ovary, with two or many amphitropal ovules on their inner face. Fruit capsular, 2-valved, sometimes 1-celled, with a large placenta filling the capsule, sometimes somewhat 2-celled, with the dissepiments incomplete. Seeds reticulated; albumen abundant, cartilaginous; embryo conical, with its radicle next the hilum. For many years it has been considered that *Hydroleaceæ* was a distinct order from *Hydrophyllaceæ*, but recent botanists recognise so little distinction between them, that they are now both included in the above definition. Dr. Lindley places *Hydrophyllaceæ* near *Primulaceæ* *Plumbaginaceæ*, and *Boraginaceæ*. Some of the species are cultivated in gardens for the sake of their gay flowers, but none appear to possess useful qualities of any importance. They are mostly found either in the north or south provinces of America, and are not known much beyond that continent. *Nama* and *Hydrolea* are found in the East Indies. In the United States a decoction of *Hydrophyllum Canadense* is one of the many remedies for snake bites. *Hydrolea* is bitter, and the leaves are applied as a poultice in India. Many of the species, especially those of the genera *Nemophila* and *Eutoca*, are beautiful objects, and are extensively cultivated in our gardens. There are 16 genera and 75 species.

(4414) HYLOBATES, (from the Greek, signifying wood-walker, or one that goes through woods), Illiger's name for the Long-Armed Apes, or Gibbons. The general character of these Apes as to dentition and form agree with those of the Orangs; but there is some modification of the dental system in the Gibbons, which have also longer anterior extremities and have posterior callosities, though they have no tail. The vermiform appendix of the cæcum is also shorter. Dental formula:—Incisors $\frac{4}{4}$: canines, $\frac{2}{2}$: molars $\frac{12}{12} = 32$, F. Cuvier takes this type of dentition from the Siamang, and says that it is also found in the Wow-Wow and Onko. The height of the Gibbons rarely exceeds four feet, and when they are placed in an erect posture their upper extremities reach the ground. The species are found all over India and its islands. The forests are the haunts of these creatures, and they are rarely seen at a distance from them. Gregarious, but shy and timid, they keep up a howling concert, resembling in this respect in some degree the Howling Monkeys of America, and having some of them guttural sacs like that tribe. In the forest the activity of certain species is great, and they make way on the trees with their long arms and lengthened feet most rapidly; but when surprised on open plain ground, they are altogether as helpless. Other species (the Siamang, for instance) appear to be more sluggish; but these make good use of their acute eyes and ears, and are generally off before the enemy approaches near enough for a capture. In confinement they are gentle, and seem capable of great attachment to those who are attentive to them. Dr. Burrough gives a most interesting account of three individuals of the species called Hoolock (*Hylobates Hoolock*), which he had an opportunity of observing. One of them, a male, showed a most amiable and docile disposition; and a young female, which died early, was equally gentle and pacific. The Siamang kept by Sir Stamford Raffles was, according to Dr. Horsfield, very tame and tractable, and was never happy unless it was in the company of some person. Mr. George Bennet gives a lively description of the affectionate manners of another of these apes towards those who made its captivity light by their kindness.—*Eng. Cyc.*

(4415) HYLOBATES AGILIS, the Wow-Wow, or Active Gibbon, may be taken as an example of the genus. It has the forehead very low; orbitary arches very projecting; face blackish-blue in the male, and brown in the female; in the former a white band over the eyes, which unites with the whitish whiskers. Hair of the body fine, except about the neck, where it is longer and inclined to be woolly and curled; upper part chocolate-brown; back and fore part of the thighs yellowish-brown, but the colour varies a good deal according to the sex and age, the young being paler than the adults and aged, and the very young uniform yellowish-white. Height about 2 feet 7 or 8 inches. No guttural sac. It is very agile in its habits. As soon as they reach the forest they set pursuit at defiance, swinging, leaping, and throwing themselves from tree to tree with great rapidity. Notwithstanding the want of the guttural sac they howl in a manner very nearly resembling the Siamang, which has one. In captivity they are not very lively, as might be expected, from the impossibility of their exerting that freedom of motion on which their vivacity in a state of nature so much depends; but though timid they are soon re-assured, take pleasure in being caressed, and become familiar and even playful. This species is found in the forests of Sumatra, where the species is named Ungaputi. The Siamang of

the Malays, *Simia syndactyla* of Sir Stamford Raffles's 'Catalogue of a Zoological Collection made in Sumatra' ('Linn. Trans.,' xiii. 241), *Pithecus syndactylus* of Desmarest, *Hylobates syndactylus* of F. Cuvier, has a peculiar formation of the hands or feet of the lower extremities, the index and middle fingers being united as far as the middle of the second phalanx. This peculiarity would seem to indicate a generic distinction, notwithstanding the similarity of the teeth and skull to those of the rest of this tribe. These Sumatran Apes, sluggish and timid as they are, exhibit strong maternal affection; for though, if any of the troop are wounded, the rest abscond and leave them to their fate, the mother will remain with her little one if it is hurt, and suffer herself to be captured rather than abandon it. The females are also generally very attentive to their offspring, according to the accounts given by Messrs, Diard and Duvaucel. The following species are given in the 'British Museum Catalogue':—

(4416) HYLOBATES HOOLOCK, the Hoolock. It is the Simia Hoolock, Harlan; *H. Seyrites* and *H. Coromandus*, Ogilby; *H. Houlock*, Lesson. Asam (?).

(4417) HYLOBATES AGILIS, the Ungha; *Pithecus agilis* Desmarest; *H. variegatus*, Muller; *H. Raffiasii*, Geoffroy *H. Lar* F. Cuvier. Black specimens are marked from the Himalaya and brown from Malacca.

(4418) HYLOBATES LAR, the Gibbon; *Homo Lar*, Linnæus; *Simia longimana*, Schreber; *S. albimana* Vigors and Horsfield; Le Grand Gibbon of Buffon. It is a native of Malacca.

(4419) HYLOBATES LEUCISCUS, the Silvery Gibbon, or Wow-Wow *Simia leucisca*, Schreber, Moloch, Audeb. Malacca.

(4420) HYMENÆA (from 'Hymen,' in reference to its twin leaflets), a genus of Plants belonging to the natural order *Leguminosæ*. It has a calyx furnished with two bracts at the base; the tube turbinate, coriaceous; the limb 4-5 parted, deciduous, with two lobes sometimes united into one; 5 petals nearly equal, glandular; 10 stamens, distinct, inflated in the middle; the style filiform; the legume woody, oblong, many seeded, containing fecula; the embryo straight. The species are trees, with bifoliate leaves, and corymbs of white or yellow flowers.—*Eng. Cyc.*

(4421) HYMENÆA COURBARIL, Locust-Tree, or Gum-Anime Tree, has oblong ovate leaflets, unequal-sided, and unequal at the base ending in a long point with the legume oblong, compressed, yellowish, shining. It is a fine lofty spreading tree, and grows in the tropical parts of America, in Jamaica, and in Tenasserim. The seeds are enveloped in a cellular mealy substance, which is sweet like honey, and is eaten by the Indians with great avidity. When fresh it is slightly purgative, but by keeping it loses this property. A decoction of this substance, when allowed to ferment, forms an intoxicating drink resembling beer. From between the principal roots of this tree there exudes a fine transparent resin, of a red or yellowish-red colour, and which is collected in large lumps and sold under the name of Gum Anime, or Gum Animi. This resin resembles amber, is very hard, and sometimes contains leaves, insects, or other object imbedded in it, which remain in a perfect state of preservation. It burns readily, emitting a very fragrant smell. Dissolved in rectified spirits of wine it makes one of the finest kinds of varnish. According to Lindley this resin is called Jatahy, Jatchy, or Copel, and in Minas Geraes, Jatoba. Courbaril is the name of the tree in some parts of South America. In countries where this tree grows, the resin is used medicinally, and has also been employed in that way in Europe. It acts as a stimulant when taken internally, and as an irritant when applied externally. In fumigation it has been employed for persons labouring under asthma and dyspnœa. Dissolved in spirits of wine or oil it is used as an embrocation in rheumatism. Internally it has been recommended as a substitute for guaiacum, in venereal disease, and chronic rheumatism. The inner bark, either in the form of tincture or decoction, is administered as a vermifuge. The curadores have a method of mixing it with sugar and rum, so as to make a very agreeable emulsion or syrup. The wild bees are fond of building their nests in the trunk of this tree. The timber of the old trees is very hard and tough, and is in great request for wheel-work, particularly for cogs The wood is so heavy that a cubic foot is said to weigh a hundred pound: it takes a fine polish.—*Eng. Cyc.* The trunk acquires an immense height; the wood is used by cabinet makers, is very hard, and acquires a fine polish. When in a sickly state, it furnishes the resin called *Western Anime.—O'Shaughnessy, p.* 314. *Hymenæa Courbaril* was introduced into Tenasserim, by Major Macfarquhar, and is easily propagated.—Several other species of *Hymenæa* are described, but of these comparatively little is known. The Copal of Madagascar, and probably of the East Indies generally, is furnished by *H. verrucosa*. The Locust-Trees of the West have long been celebrated for their gigantic stature, and other species are the Colossi of South American forests. Some of them are, according to Martius, 84 feet in circumference at the bottom, and 60 feet where the boles become cylindrical. (Don, *Dichlamydeous Plants*; Lindley, *Flora Medica.*)—*Eng. Cyc.*

(4422) HYMENODICTYON EXCELSUM, Wallich, in Roxb Fl. Ind. ii. 148, (ed. 1828) *Syn.* Cinchona excelsa, Roxb. Fl. Ind. i. 529. Saggapoo Marum or Cedar Wood, Hymenodictyon excelsum.

Kundaroo, Bundaroo, Kala Buchnak, Hind. | Pundaroo, Tel.

This species of Hymenodictyon is a native of the mountainous parts of the Circars and chiefly of the vallies, where it grows to be a very large tree. Flowers during the rainy season. Seeds ripe in four or five months after. The wood is firm, close grained of a pale Mahogany colour, and very useful for many purposes. *Rox.—Rohde M.S.S.* The two inner leaves of the bark possess great bitterness and astringency ; the bark is used by the tanners, and also as a medicine among the Hindoos, in cases requiring astringents. Dr. O'Shaughnessy, analysed the bark from the Botanic Garden of Calcutta, but could detect no alkaline ingredient ; nevertheless the trees of hilly regions may furnish the valuable desideratum. The stamina being contained within the tube affords much ground for expecting the discovery of a febrifuge alkaline in this species.—*OSh. p.* 394. It is common all round the foot of the Neilgherries, wood much used and esteemed for inside work such as drawers &c.—*Mr. McIvor.* Pundaroo is the Telingoo name of this large tree, which grows in the mountainous parts of the Northern Circars, of Peninsular India : the bark of which, Dr. Roxburgh informs us, possesses both the bitterness and astringency of the Peruvian bark, and when fresh, even in a stronger degree.—*Ain's. Met. Mad. p.* 104.

(4423) HYMENODYCTION OBOVATUM. Icon. 1159.

Yella malakai marum, Tam.

A tree, but Dr. Wight was unacquainted with its dimensions or quality of the wood ; no specimens having been sent.—*Wight.*

(4424) HYMENODYCTION UTILE. Rubiaceæ, Icon. 1159.

Peroonjoly marum, Tam.

When Dr. Wight first gathered specimens of this tree, he was informed that it furnished the wood called bastard cedar. This information, if correct at all, can only be partially so, as he has since found two others similarly reported, the tree attains a large size and the heart wood is red, but its qualities are not known.—*Wight.*

(4425) HYOSCIAMUS HYOSCYAMIFOLIA, L. D. (Hyoscyamus, E.) Leaves. Hyoscyami Semina, L. and, Seeds of Hyoscyamus Niger, Linn. Henbane. Henbane has been employed in medicine from the earliest times ; is the *ὑοσκυαμος* of the Greeks, and the *bunj* of the Arabs. The seeds are known by the name of *Khorassani Ujwain* in India. Henbane (fig. 83) is annual or biennial, that is, plants grown from the seed of the biennial variety will, in favourable conditions of the soil and climate, come to full perfection in the first year. Roots spindle-shaped, those of biennial plants having considerable resemblance to small parsnip-roots in the winter and spring. (*Houlton.*) The plants in the first year throw up a tuft of radicle leaves which are petiolated, woolly, and possess little of that clamminess and odour which are peculiar to the mature plant. In the second spring, another set of leaves make their appearance with, and attached to the flowering stem. This is from a foot to 3 feet high, seldom branched, hairy, hairs glandular, viscid. Leaves sessile, subamplexical, occasionally decurrent, lower ones sometimes stalked, oblong-acute, coarsely and unequally cut or sinuate, appearing pinnatifid, clammy, and fœtid, of a pale dull green colour, slightly pubescent, with long glandular hairs, like those of the stem, upon the midrip. Flowers nearly sessile, axillary, subsolitary, unilateral, erect, much shorter than the leaves. Calyx funnel-shaped, 5-lobed, villous. Corol (2) funnel-shaped, limb spreading, 5-lobed, not quite equal, of a dull straw-colour, marked with dark purple veins. Stamens 5, declinate ; filaments pubescent. Ovary ovoid, shining, 2-celled, with numerous ovules attached to the placentæ. Style filiform Stigma (1) capitate. Capsule opening transversely by a convex lid, 2-celled, many seeded. Seeds small, roundish, finely dotted, of a light grey colour.—Indigenous in waste grounds throughout Europe, also in the Persian region of Botanists.—Nees von E. 192. St. and Ch. 9. Henbane plants come into flower about the beginning of June, but the annual plants a little later : the seeds ripen from August to October. Mr. Houlton is of opinion that the biennial plant should alone be employed medicinally, and that the leaves should be collected when the first flowers begin to appear. But it has not been proved that annual plants, when properly grown, are devoid of active properties. Dr. Royle was in the habit of largely cultivating Henbane in the Botanic garden at Saharunpore, where, from the nature of the climate, the whole process of cultivation, including the ripening of the seed, was completed between the months of October and March. The Extract made from these plants was highly approved of by several medical officers, and pronounced by Mr. Twining, after trial in the General Hospital at Calcutta, to be of " most excellent quality" (Himal. Bot. p. 281). But the secretions of plants growing in a colder and moister climate, or in seasons having these characteristics, may not come to so great perfection in the first year. Dr. Christison states, from experiments made in the Royal Infirmary at Edinburgh, " that inferiority of cultivated plants, if it exists at all, seems not appreciable in practice ;" and, with respect to the period at which the leaves acquire their activity, he says, " I have found them sufficiently active even in the spring, before the appearance of the flowering stem." When collected, they should as soon as possible be separated from the stem, spread out, and dried in a warm airy room. They ought to have a mucilaginous slightly bitter taste, and should retain some of the peculiar odour of the plant. Analysed by

Brandes, the seeds yielded Gum, Starch, Albumen, a large proportion of Fixed Oil, with a variety of salts, Ligneous fibre, and an oily-like alkali, resembling Conia, which was highly poisonous. Geiger and Hesse, however, obtained groups of radiated needle-like crystals, fusible and volatile, but readily decomposed when distilled, alkaline in nature, neutralizing acids and forming crystallizable salts, soluble in Alcohol and Ether, less so in water. These have been considered pure *Hyoscyamia*, which is very poisonous, dilates the pupils, and when moistened, smells strongly of Tobacco. The oily-like liquid of Brandes is thought to hold a little of this principle in solution. A highly poisonous empyreumatic oil is obtained by destructive distillation, as from the other solaneæ and from Foxglove.—*Action. Uses.* Narcotic, Anodyne, and Soporific. Available for a variety of cases where we wish to relieve pain, allay irritability, and procure sleep, having the advantage of not constipating the bowels like Opium. Hence it is frequently prescribed with Calomel, Purgatives, or with Antispasmodics. It may be given internally in powder in doses of gr. v.—gr. x. or in Extract or Tincture; or it may be applied externally in the form of fomentation, or in cataplasms of its leaves, or its Extract or Tincture used as those of Belladonna, p. 511.—*Royle p.* 515.

(4426) HYOSCYAMUS, EXTRACT OF. A large fresh specimen was forwarded from Hoonsoor, prepared by Asst. Surgeon Hilbers, the quality of the extract has been thoroughly tested in the different Civil Dispensaries, and it has been pronounced equally useful as the European article, considering that this valuable medicine has been prepared for the first time in the Presidency, the Jury award a 2d Class Medal.—*M. E. of* 1855. In 1841, the Bombay medical stores were supplied with this drug, from the Dapooree garden.—*Spry's Suggestions, p.* 36.

(4427) HYPERANTHERA MORINGA: Horse Radish tree.

Sujuna, Suhnjna, Hind.

Common in gardens in Southern Asia.—*Gen. Med. Top. p.* 192.

The root.

Moorungy vayr, Tam.	Moonaga vayroo, Tel.
Moongay ke jar ke jurr, Duk.	*Ainslie's Mat. Med. p.* 265.

See article Horse Raddish.

The greens.

Moorungy keeray, Tam.	Sheggooroo, Sans.
Moongay ke baujee, Duk,	*Ainslie, page* 254.
Moonaga koora, Tel.	

The flowers.

Moorungy poo, Tam.	Moonaga poo, Tel.
Moongay ka pool, Duk.	Sheggooroo, Sans.

This is used both as a pot herb and when pickled.—*Ainslie's Mat. Med. page* 260.

The fruit.

Moorungy kai, Tam.	Moonagakaia, Tel.
Moongay ke pullie, Duk.	Sheggooroo, Sans.

This very valuable and pleasant tasted pot vegetable grows to about half a yard long, is of the size of a finger in thickness, and is commonly eaten made into curry. The tree is the Kellor of the Malays; the root of it is used as horse radish.—*Ainslie, page* 241.

(4428) HYPERICUM, a species nearly resembling *H. perforatum.* is common in the Cashmerean mountains, but is not officinal. In Arabian medicine this plant is recommended to expel intestinal worms, to cure piles, prolapsus uteri et ani. In European practice St. John's wort was regarded as a mild stimulant tonic, diuretic, emenagogue, &c. The dried herb boiled in alum-water communicates a yellow, or yellowish red color, to wool, silk, &c.—*Honigberger, p.* 289.

(4429) HYPERICUM. Hypericaceæ.—St. John's Wort. These shrubs and herbaceous plants, all bear yellow flowers with one exception, the Cochin Chinese: they are inhabitants of all parts of the world, and grown by seed in any good garden soil.

(4430) HYSSOPUS OFFICINALIS.

Zufaiy-ycabus, Arab.	Isop. Ger.
Hyssope, Fr.	Zoofæ gabis, Arab.

The officinal hyssop of Europe is well known to be considered as tonic and stimulant; and was at one time, a medicine in repute in nervous cases. This plant, which is brought to India from Syria, was held in high esteem by the ancients.—*Faulkner.* Most are aware that this owes its celebrity to a passage in Josephus, who used the hyssop as a term of comparison with the cedar to give an idea of Solomon's botanical knowledge, (*Fee, p.* 455). In the Old Testament we meet its name in several of the sacred texts: "Purge me with hyssop, and I shall be clean;" and again—"The hyssop which groweth on the wall." The dried plant is brought to India from Syria. The Arabians place it among their anthelmintics and stimulants. Pliny thought it useful in diseases of the chest. It is cultivated in the Calcutta Garden. Celsus regarded it as diuretic.—*O'Shaughnessy, p.* 488.

(4431) HYSTRICIDÆ, a family of Animals belonging to the order *Rodentia*, Sub family *Hystricina*,—This sub-family embraces the animals familiarly known as Porcupines. The genus *Hystrix* of Linnæus embraces those Rodents whose covering consists, for the most part, of a kind of offensive and defensive armour, in the shape of spines or quills, instead of hairs. Colonel Sykes has described a species under the name of *Hystrix leucurus* (Sayal of the Mahrattas),

as *Hystrix cauda alba*. He states that the animal appears to be distinct from the European species, which it closely resembles in form and covering. It is nearly a third larger. All the spines and open tubes of the tail are entirely white, which is not the case in *Hystrix cristata*. The spines of the crest also are so long as to reach the insertion of the tail. The ears are much less rounded, and the nails are shorter, infinitely deeper, and more compressed, and with deep channels below. The white gular band is more marked; and, finally, the Asiatic speces is totally destitute of hair-spines, where wanting, being replaced by strong bristles even down to the nails. ('Zool. Proc.,' 1830, 1831.) Mr. Hodgson notes this species among the *Mammalia* of Nepaul, as inhabiting the central and lower regions. ('Zool. Proc.,' 1834.) Mr. Waterhouse gives the two following species of *Hystrix*:—

(4432) HYSTRIX HODGSONI, Crestless Nepaul Porcupine; *H. alophus*, Hodgson. General hue brown-black; head brown; in the visible portions of the quills the black prevails over the white, but numerous very long and slender quills are almost entirely white, the spiny bristles which form the chief covering of the animal are rather long and slender, and have long hair-like points. It inhabits Nepaul.

(4433) HYSTRIX JAVANICUM, Java Porcupine; *Acanthion Javanicum*, F. Cuvier and Vander Hoven; *H. fasciculata*, Muller; *H. brevispinosa*, Wagner; *Acanthion Javanicum*, Gray. It inhabits Java, Sumatra, and Borneo. *Atherura* Cuv. (*Acanthion*? F. Cuv.).—Neither the head nor the muzzle convex; tail long but not prehensile; feet like those of *Hystrix*. *A. cristata*, *Hystrix fasciculata*, Shaw; Le Porcépic á Queue en Pinceau, Buff. Mr. Bennett further observes that Linnæus founded his *Hystrix macroura* on Seba's figure; but Buffon having quoted neither Seba nor Linnæus, Dr. Shaw took it for granted that this was a different animal, and consequently gave it a new name—*H. fasciculata*. Mr. Bennett entertained however but little doubt, notwithstanding some trifling discrepancies in the figures, that Sir Stamford Raffles was right in his conjecture that they both represent one and the same species. It is found in the Celebes Islands (Seba): Asia (Linn.); Malay Peninsula (Buffon); Isles of the Indian Archipelago (Pennant); Sumatra (Sir Stamford Raffles); Fernando Po (Vial).—*Eng. Cyc.*

I.

(4434) ICE.

Yuch, *erroneously termed* Burf (snow.,) Guz. Hind. Pers.

Ice is extensively used for a variety of economical purposes, such as cooling liquors, beer, fruit, in the making of ice-creams, jellies, and as an ingredient in some confections. Of late years the practice of shipping it from Boston to Calcutta Madras and Bombay, and other warm climates, has been adopted with success, and it is justly esteemed in those countries a perfect luxury.—*Faulkner*. In many countries the command of a proper supply of ice or snow for cooling water or other liquids in summer has long been regarded as one of the necessaries of life. And so ancient is the practice, that we even find allusions to it in the Proverbs of Solomon:—"As the cold of snow in the time of harvest, so is a faithful messenger to them that send him; for he refresheth the soul of his masters." xxv. 13. The most simple and obvious method of securing a magazine of cold to meet the physical wants of summer, is to collect, during the winter, a store of ice or of snow, and to place it under such circumstances that it shall be shielded from rain, from warm air, and from the direct rays of the sun. Nothing is more desirable as an appendage to markets, &c., than an ice-house, for the purpose of preserving fish, meat, fruit, and vegetables fresh much longer than can be done by other means. The simplest method of keeping ice is by enveloping it in a large quantity of loose straw. For this purpose, the ground is formed into a flattened cone, for draining off the water from any portion of the melted ice; a layer of faggots is then put therein, with straw a foot or more in thickness, and on this the ice is piled in a large conical mass, and covered with straw to the thickness of one foot, then with faggot-wood to the thickness of two feet, for the purpose of preserving a stratum of air above and around the ice; and lastly, the whole is covered with two or three feet of straw arranged as a thatch. Of late years, ice has become an article of commerce between countries where it is found in abundance, and those where it is found scantily or not at all. The place where this remarkable traffic commenced, is Wenham Lake, about 18 miles from Boston, in the United States of America; and subsequently, some of the Norwegian lakes have furnished abundant supplies. The Wenham Lake Company was formed, and we learn from the *Illustrated London News* some particulars respecting their proceedings. In September, 1833, a cargo of ices shipped at Boston, was discharged at Calcutta, and sold at 3d. per lb. It was packed in large cubes, fitting

osely together so as to form one solid mass, ithin chambers of double planking with a layer well-dried refuse tan, or bark, between them. he quantity shipped, was 180 tons, of which out 60 wasted on the voyage, and 20 on the ssage up the river to Calcutta. Thousands of ns are now annually shipped from Boston to the ast Indies, to the West Indian Archipelago, and the continent of South America. The company have erected extensive ice-houses in London and at Liverpool, and have arranged for nporting into England thousands of tons of e every year. The masses are so large, that hey expose a very small surface to the action of he air, and hence they suffer but very little loss. t is also stated, that ice frozen upon deep water s more hard and solid than ice of the same thickness obtained from shallow water, and melts nore slowly. In Great Britain, the collection nd storing of ice is very precarious, on account of the uncertainty of the supply during our mild winters; but in America, where the cold of winter is intense, the cutting, storing, and transportation of the ice is regularly carried on throughout the winter. Wenham lake occupies an elevated position and lies embosomed in rugged hills. The lake has no outlet, but is fed by the springs which issue from the rocks at its bottom, at a depth of 200 feet. The ice-house, which is capable of storing 20,000 tons of ice, is built of wood, with double walls 2 feet apart all round, the intervening space being filled with sawdust. The machinery used for cutting the ice is worked by men and horses. From the time when the ice first forms, it is kept free from snow until it is thick enough to be cut; the cutting being commenced when the ice is a foot thick. A surface of some 2 acres is then selected, which, at that thickness, will furnish about 2,000 tons, and a straight line is then drawn through its centre from side to side each way. A small hand-plough is pushed along one of these lines, until the groove is about 3 inches deep and ¼ inch wide, when the marker, is introduced. This implement is drawn by 2 horses, and makes 2 new grooves parallel with the first, 21 inches apart, the gauge remaining in the original groove. The marker is then shifted to the outside groove, and makes 2 more. Having drawn these lines over the whole surface in one direction the same process is repeated in a transverse direction, marking all the ice out into squares of 21 inches. Meanwhile the plough drawn by a single horse follows in these grooves, and cuts the ice to a depth of 6 inches. One entire range of blocks is then sawn out, and the remainder are split off toward the opening thus made with an iron wedge, called an *ice spade*, when it is dropped into the groove the block splits off with a very slight blow, especially in very cold weather; the labour of *splitting* being slight or otherwise according to the temperature of the air. Low platforms are placed near the opening made in the ice with iron slides extending into the water, and a man stands on each side of a slide armed with an ice hook, with which he catches the ice, and by a sudden jerk throws it up the slide upon the platform. In a cold day everyt hing is quickly covered with ice by the freezing of the water on the platforms, slides, &c. and the huge blocks of ice, some of which weigh more than 2 cwt. each, are hurled along these slippery surfaces with great ease. By the side of the platform is a sled of the same height, capable of containing about 3 tons, which when filled, is drawn over the ice to the front of the sto re-house, where a large stationary platform of the same height is ready to receive its load, which, as soon as discharged, is hoisted a block a time into the house. Forty men, assisted by 12 horses, will cut and stow away 400 tons a day. Sometimes in favourable weather 100 men are employed at once. When a thaw or fall of rain occurs, the ice is made porous and opaque and unfitted for the market: when snow is followed by rain, and that by frost, the snow-ice thus formed is removed by the *plane*. The operation of planing is somewhat similar to that of cutting. A plane gauge to run in the grooves made by the marker, and which shaves the ice to the depth of 3 inches, is drawn by a horse, until the whole surface of the ice is planed. The chips thus produced are then scraped off, and if the clear ice is not reached the process is repeated. If this makes the ice too thin for cutting, it is left until a few nights of hard frost shall have added below as much as was removed from above. In addition to filling their ice-houses at the lake and in the large towns, the Company fill a large number of private ice-houses during the winter; all the ice for these purposes being transported by railway. We come now to the second part of our subject —the production of ice artificially; the most ancient example of which was probably that carried on in the upper country, near the town of Hoogly, about 40 miles from Calcutta. By a skilful application of the process of evaporation the natives are able to procure a supply of ice during their short winter, viz. from the end of November to the middle of February. The ground where the ice is made is a large open plane: 3 or 4 troughs are formed, each about 120 feet in length by 20 feet in width and 2 feet in depth: the bottom is made smooth and allowed to dry by exposure to the sun. It is covered with bundles of rice straw to the depth of about a foot, and then loose straw is strewed in, to within 6 inches of the adjoining land. The water to be frozen is contained in pans of unglazed porous earthenware, very much like those put under our garden flower-pots, and these are arranged in regular order close to each other upon the loose straw in rows to the number of 5 or 6,000. The natives fill the pans with soft

water by means of small earthen pots, attached to the end of bamboo-rods, long enough to reach half way across the trough. The water is taken from large water-jars sunk deep in the ground near the pits where the ice is stored, and filled from the neighbouring pools or with drainings from the ice. The quantity of water poured into each pan varies from ½ to ⅓ of a pint, depending upon the clearness of the sky and the steadiness of the wind. The most favourable wind is from the NN. W: but any point between N. and W. will do, although less ice is produced. If the wind is between E. and S. no ice will be formed. The ice which begins to appear a little before midnight, is carefully watched by persons stationed near each trough. As soon as a slight film of ice appears, the contents of several pans are mixed together, and the freezing liquid sprinkled over the others. The freezing continues till sunrise, when perhaps as much as half an inch of ice will be found in each pan. In very favourable nights the water is entirely frozen. The ice is generally removed by women, 7 or 8 of whom are appointed to each ice-bed: they use a blunt semi-circular knife to scoop out the ice, which they throw together with any unfrozen water into earthen vessels placed near them. When these are full their contents are poured into conical baskets, placed over the large water-jars from which the pans are filled; by which means a supply of cool water is collected for the next night's operations. When the ice has been sufficiently drained, it is deposited in wells near the ice-beds; and at night removed to large circular pits lined with mats, and covered over with a straw shed. The heat of the day, even in the ice-making season, is frequently greater than that of the hottest summer days of England, so that after all precautions, a partial thawing goes on in the pits. The water thus produced was carried off through holes in the bottom of the pits to a deep well, which also serves to supply the pans in the ice-bed; thus throughout the process the cold is economised as much as possible. The ice was conveyed in boats to Calcutta by night. When the weather was coldest it was simply packed in bags; at other times in baskets lined with straw mats, and conveyed to the city before sunrise. During the hot season, when ice was most needed, it was scarcely possible to preserve it in any quantity, and the first heavy fall of rain usually melts all that is left of the last ice-making season. Some of the most useful freezing mixtures are given in the following table:—

MIXTURES.	PARTS.	THERMOM. SINKS.
Sal Ammoniac, ...	5	
Nitre, ...	5	from 50° to 10°
Water, ...	16	
Nitrate of Ammonia,	1	
Water, ...	1	„ 50° „ 4°
Sulphate of Soda, ...	5	
Dilute Sulphuric Acid, ..	4	„ 50° „ 3°

Snow,...	1	from 32° to 0°
Common Salt, ...	1	
Muriate of Lime, ...	3	„ 32° „ —50°
Snow, ...	2	
Snow, ...	2	
Dilute Sulphuric Acid,	1	„ —10° „ —56°
Dilute Nitric Acid,...	1	
Snow, or Pounded Ice.	12	
Common Salt, ...	5	„ 18° „ —25°
Nitrate of Ammonia,	5	
Snow, ...	1	
Muriate of Lime, ...	3	„ —40° „ —73°
Dilute Sulphuric Acid,	10	
Snow, ...	8	„ —68° „ —91°

Ice and salt furnish the cheapest and most convenient freezing mixture; but where ice cannot be procured the salts mentioned in the first two recipes given above may be used, and the salts recovered by evaporation when they have served their purpose, so that they can be used over again.—*Tomlinson.* Mr. Fortune tells us that on the right bank of the Ning-po river, above the town and fort of Chinhæ, and in various other parts of the north of China he met with ice-houses. When he inspected them for the first time in 1843, their construction and situation differed so much from what he had been accustomed to see in England, differing, too, in things which he used to consider as indispensable to an ice-house, that he had great doubts regarding their efficiency; but at the end of August 1854, he found many of these houses were yet full of ice, and then seemed to answer the end most admirably. The town of Ning-po stands in the midst of a level plain from twenty to thirty miles across. These ice-houses are built on the sides of the river in the centre of the plain, completely exposed to the sun—a sun, too, very different in its effects from what is experienced in England,—clear, fierce and burning; which would try the efficiency of the best English ice-houses as well as it does the constitution of an Englishman in China. "The bottom of these ice-houses is nearly on a level with the surrounding fields, and is generally about twenty yards long, by fourteen broad. The walls which are built of mud and stone, are very thick, twelve feet in height, and are, in fact, a kind of embankment rather than walls, having a door on one side level with the floor, for the removal of ice and a kind of sloping terrace on the other, by which the ice can be thrown into the house: on the top of the walls or embankment a tall span roof is raised, constructed of bamboo, thickly thatched with straw, and in appearance exactly like an English haystack. And this is the simple structure which keeps ice so well during the summer months, and under the burning sun of China." "The Chinaman, with characterestic ingenuity, manages also to fill his ice-houses in a most simple way and at a trifling expense. Around the house he has a small flat level field connected with the river. This field he takes care to flood in winter before the cold

weather comes on. The water then freezes and furnishes the necessary supply of ice at the very door. Again in spring, these same fields are ploughed up and planted with rice, and the water which drains from the bottom of the ice-house helps to nourish the young crop. Of course here, as in England, when the house is filled the ice is carefully covered up with a thick coating of straw. Thus the Chinaman, with little expense in building his ice-house, and an economical mode of filling it, manages to secure an abundant supply for preserving his fish during the hot summer months. "It now, I think, becomes a question whether we could not build ice-houses at less expense and more efficient, upon the Chinese plan, than upon the old under ground system common in England. An accompanying sketch enables one to form an idea of the appearance which these ice-houses present to the traveller in going up the Ning-po river. Ning-po, August, 1844." Since this letter was published I have had frequent opportunities of testing the qualities of the Chinese ice-house, both at Ning-po and also at Chusan and Shanghae, and I have found that it answers the purpose admirably. The winter of 1844-1845 was unusually mild in this part of China; little or no ice was formed on the ponds and canals, and of course the ice-houses could not be filled; but many of them contained large quantities which had been laid up the year before, and by this means the market was supplied with ice which had been in store at least a year and a half, and would probably have kept some time longer. The ice is of great importance to the Chinese, who depend so much for their food upon the fish which is caught in their waters. They are enabled by this means to keep their fish during the hottest weather for a considerable time and transmit them in this way to different parts of the country.—*Fortune Residence.*

(4435) ICELAND MOSS.

Cetraria, Lat.

A lichen (*Cetraria Islandica*), common in the North of Europe and North America, which yields a nutritive starchy substance, sometimes employed to make bread and gruel. It may be formed into a paste; and from its possessing demulcent qualities, as well as a bitter principle, it is extensively employed in consumptive diseases, being regarded as a dietetic, as well as a therapeutic agent. *Waterston.—Faulkner.*

(4436) ICHNEUMON, a genus of Insects belonging to the order *Hymenoptera*, section *Terebrantia*, and family *Pupivora*, in the arrangement of Latreille. The genus, as defined by Linnæus, included such pupivorous *Hymenoptera* as are furnished with veined wings (the anterior pair presenting in their disc several complete or closed cells), filiform or setaceous vibratile antennæ composed of a great number of articulations, and an ovipositor of various length and complicated structure. The Linnæan genus now constitutes a group including a great many well-marked genera and an immense assemblage of species. All these are remarkable for the habits of their larvæ, which are parasitic in the bodies of other insects. These bodies the perfect Ichneumons perforate by means of their ovipositors, and there lay their eggs. This destructive habit gave rise to the name by which they are known; a comparison being drawn between them and the Egyptian Ichneumon (*Herpestes Ichneumon*) the quadruped celebrated as the destroyer of serpents and crocodiles.—*Eng. Cyc.*

(4437) ICHNOCARPUS (from ἴχνος, a footstep vestige, and καρπος, a fruit, in reference to the slender follicles), a genus of Plants belonging to the natural order *Apocynaceæ*. It has a salver-shaped corolla, 5-cleft calyx, and inclosed stamens; sagittate anthers, free from the stigma. The species are climbing shrubs with opposite leaves; the flowers in branched terminal panicles, white and inodorous.—*Eng. Cyc.*

(4438) ICHNOCARPUS FRAGRANS has oblong lanceolate leaves tapering to both ends, and axillary trichotomous spreading peduncles. It is a native of Nepaul, and has large handsome flowers.—*Eng. Cyc.*

(4439) ICHNOCARPUS FRUTESCENS, has a twining stem, oblong-lanceolate leaves tapering to both ends, axillary peduncles very long and racemose. It is a native of Ceylon and Nepaul. The flowers are small and purple; the leaves deep green above and pale beneath. According to Dr. Royle, it is sometimes used in India as a substitute for Sarsaparilla, and it is also mentioned by Afzelius in his 'Remedia Guinensia,' as a medicinal plant.—*Eng. Cyc.*

(4440) ICHNOCARPUS LOUREIRII, has a frutescent stem, ovate oblong leaves, lateral 3-flowered peduncles. It is a native of Zanzibar. All the species of *Ichnocarpus* grow well in a mixture of loam, peat and sand, and cuttings strike readily in sand under a hand-glass (Don, *Dichlamydeous Plants*; Lindley, *Flora Medica.*)

(4441) ICHTHYOLOGY. The branch of science which comprehends a knowledge of the structure, nature, and forms of Fishes is thus called.—See Fishes of Southern Asia.

(4442) ICHTHYOPHIS GLUTINOSUS, an immense earth worm, common in Sikkim. It is a native of the Khasia Mountains, Singapore, Ceylon and Java.—*Hooker Him. Jour. Vol.* II. *p.* 25.

(4443) ICICA, a genus of Plants belonging to the natural order *Burceraceæ*. It has a small obtusely 5-toothed calyx; 5 petals inserted under the disc, recurved, sessile, valvate; 10 stamens shorter than the petals inserted with them; a cup-shaped disc with 10 crenatures at the margin; a sessile 5-celled ovary with two collateral pendules ovules in each cell; a very short style; a 5-angled stigma; a globose obtuse 1-3-celled

drupe with thick and fleshy dissepiments; resinous seeds without albumen. The species are shrubs or trees with unequally pinnate leaves, and white flowers seated on panicled racemes which are terminal or axillary.—*Eng. Cyc.* There are several species of *Icica*, all of which yield the same transparent fluid, resembling turpentine in many of its properties. *I. Icecariba*, a native of Brazil, yields a resin, which is brought into the market under the name of Gum Elemi, but is not the true gum of that name. *I. decandra* is found in the woods of Guyana, where it is called Chipa. The fluid which exudes from it yields on evaporation a resin. *I. altissima* grows in Guyana. There are two varieties of this tree, known by the name of White Cedar and Red Cedar. The latter is a very durable wood, and is used for making household furniture, boats, canoes, &c. (Don, *Dichlamydeous Plants*; *Outlines of Botany*; Lindley, *Flora Medica.*)—*Eng. Cyc.*

(4444) ICICA HEPTAPHYLLA, has 5-7-stalked oblong acuminated leaflets, with the racemes few-flowered, somewhat corymbose, and six times shorter than the petiole. It is a small tree, a native of the woods of Guyana, where it is called Arbre d'Encens. The whole plant is sweet-scented, and like the last species yields a clear balsamic fluid when it is wounded. It is burned as a perfume, and used as a remedy in dysentery. The seeds are contained in a viscid pulp which hardens into a gray resin, and is used by the natives for burning as a perfume. The carib name of this tree is Arouaoo.—*Eng. Cyc.*

(4445) ICICA HETEROPHYLLA, has ternate or pinnate leaves, with stalked, ovate, acuminated, entire, simply-veined leaflets; the racemes simple, rather shorter than the leaves. This plant is the *I. Aracouchini* of Aublet. It is a tree 50 feet in height, growing in Guyana, on the banks of the river Couron, where it is called by the natives Aracouchini. When an incision is made in the bark of this tree a yellow balsamic aromatic fluid exudes, which retains its fluidity a long time after exposure to the air. This fluid is used by the Guyanese as an application to wounds. A resin is found also in the seeds, and the natives of Guyana carry the nuts about with them on account of the scent they give out. These nuts they often send as presents to their friends. The Caribs also use the exudation for mixing with oil, with which they anoint their bodies.—*Eng. Cyc.*

(4446) ICTHYOCOLLA, a name derived from ἰχθυς a fish, and κολλα glue, is translated Isinglass, a word derived from the German *Hausenblase*, from *hausen*, the great sturgeon, and *blase*, a bladder, being one of the coats of the swimming-bladder of Fishes, chiefly of the genus Acipenser, or Sturgeon, and of which the best qualities are imported from the rivers of Russia, flowing into the Black and Caspian Seas, but also from the Sea of Aral, and the Lake Baikal. Isinglass is also imported from Brazil, and likewise from India. Of late the quality of this has been much improved. Isinglass is the purest known form of Animal Jelly; and it is therefore as Gelatine that it is valuable. Gelatine, when pure, is transparent, and nearly colourless, devoid of both taste and smell, easily preserved when in a dry state, but soon putrefying when moist. It is soluble in the different dilute acids, as well as in the fixed alkalis. Its solution forms a copious precipitate on the addition of Tannin, and which smells like tanned leather. As Corrosive Sublimate does not precipitate Gelatine, it serves to distinguish it when in solution from Albumen. Gelatine unites with a large proportion of water, and on cooling becomes a soiled tremulous mass. By boiling with Sulphuric Acid it may be converted into a kind of Sugar. Isinglass in its purest form is white, semitransparent, devoid of smell or taste, softening in old water, and dissolving in boiling water, with the exception of a minute proportion of earthy impurities. Bengal Isinglass, analysed by Mr. E. Solly, yielded, in three specimens, respectively 86·5, 90·9, and 92·8 per cent. of Gelatine.—*Royle.*

(4447) ICTIDES, a name given by M. Valenciennes to the Benturongs, a genus of Plantigrade *Mammalia*, which E. Cuvier had previously referred to the genus *Paradoxurus*. It is the *Arctictis* of Temminck.

(4448) ICTIDES ALBIFRONS. Fur gray; hairs long, silky, black at the base, and white in their extreme third, short on the head and limbs; sides of the snout, forehead, pencils of the ears (which are edged with white), black; upper part of the snout and forehead white; iris yellow; belly, gray, with shorter hairs than those on the upper parts of the body. Size, that of a very large domestic cat. In another specimen the sides of the snout and the tail, its extremity excepted, were gray. It inhabits Bootan, Nepaul (Káchar: though they occasionally occur in the central region of Nepaul. Hodgson). Sir Thomas Stamford Raffles describes the gait of this Benturong as low and crouching, the body being long and heavy, and the legs short. The tail, thick at its insertion, gradually tapers to the extremity, where it curls upwards. In climbing trees the animal is assisted by this tail, which is strong. One that was kept alive many years by Major Farquhar partook both of animal and vegetable food. Slow in motion, and timid in disposition, the animal sleeps much during the day: the night is the season of its comparative activity. Two other species have been described.—*Eng. Cyc.*

(4449) IGUANIDÆ, an extensive family of Saurians, of which the genus *Iguana* may be considered the type. Messrs. Dumeril and Bibron, in their 'Erpetologie' (1837), treat of these reptiles under the name of Lezards Iguaniens,

on Sauriens Eunotes. In 'the Catalogue of the Specimens of Lizards in the British Museum' the *Iguanidæ* with the *Agamidæ* constitute the tribe *Strobilosaura.—Eng. Cyc.*

(4450) ILLECEBRUM, a genus of Plants the type of the natural order *Illecebraceæ*. It has 5 sepals slightly cohering at the base and horned at the back. Petals absent or 5, subulate, inserted with the 5 stamens on a perigynous ring; a 1-celled 1-seeded furrowed capsule bursting along the furrows. One species is a small trailing shrub with opposite leaves having scarious stipules at the base.—*Eng. Cyc.* Wight gives Illecebrum brachiatum, 1776.

(4451) ILLECEBRUM LANATUM. Root of the woolly Illecebrum. Lin.

Sirroopoolay vayr, Tam.	Astmabayda, Sans.
Kut kejar, Duk.	

This root is considered as demulcent, and is prescribed in cases of strangury in the form of decoction. The Teloogoo name of the plant is Pindic Conda.—*Ains. Mat. Med. p.* 115.

(4452) ILLECEBRUM SESSILE. Lin.

Poonarkany, keeray, Tam.	Poonaghenti koora, Tel.
Poonaghuttie ke bawjee, Duk.	Priasattic, Sans. —*Ain's. Mt. Md. p.* 256.

(4453) ILEX, is a name given to two very different plants. As that of a species, it indicates the Evergreen Oak of the South of Europe, or *Quercus Ilex*: as that of a genus, it belongs to the Common Holly, *Ilex Aquifolium*, the type of the natural order *Aquifoliaceæ*. This latter plant, which constitutes so beautiful a feature in the winter scenery of many parts of England, and whose scarlet yellow berries render it so universal a decoration of churches (hence the name Holly-Tree, or Holy-Tree) and dwelling-houses at Christmas time, is in Great Britain upon the most northern limits within which it ranges in a wild state. It is however at those limits that it attains its greatest size and beauty; but it occasionally suffers from severe winters. It is common in the middle of Europe, and the southern side of the range of the Caucasus, where it is only a bush, and it probably extends far to the eastward. It is chiefly valued as a shelter in winter, and an ornamental tree, but its fine-grained heavy compact timber is used for a great number of useful purposes, especially by the turner and mathematical instrument maker; the black handles of metal teapots are carved out of its wood. It is also employed medicinally; the leaves and bark possess febrifugal powers of a strongly-marked character: the root and the bark are said to be diuretic and expectorant, but the berries have the discredit of being poisonous, producing purgative and violent emetic effects. Besides the Common Holly and its numerous varieties, the genus *Ilex* comprehends a large number of species, the most remarkable of which are the *I. Balearica*, or broad-leaved species of Minorca, a very handsome kind which is hardy in the middle and south of England: the *I. vomitoria*, or Cassena-Tree of the North Americans, whose leaves possess strongly-marked emetic qualities: and the *I. Paraguayensis*, or Mate Plant, of whose leaves a very large consumption takes place in South America, under the name of Tea of Paraguay. The leaves are dried, and afterwards used like the tea of the Chinese. (Loudon, *Arboretum Britannicum.*)—*Eng. Cyc.* Dr. Wight gives Ilex Gardneriana, 1217; and Wightiana, 1216.

(4454) ILEX DIPYRÆNA, is common at Mussoorce and every where in the Himalayas. It bears a very close resemblance to the holly, especially in November and December, when it is covered with clusters of scarlet berries.

(4455) ILEX SERRATA, another lofty species is also found in Mussooree, and *I. excelsa* in Nipal, (Royle, Illust. p. 167.)—*O'Shaughnessy, page* 272. In China says Mr. Williams, the order Ilicinæ, or holly, furnishes several genera of Rhamnea, whose fruit are often seen on tables. The Zizyphus produces the Chinese dates, and the fleshy peduncles of the Hovenia are eaten, the latter is quite common in Hongkong. The leaves of the Rhamnus theezans are among the many plants collected by the poorer Chinese, as a substitute for the true tea. The Chinese olive is obtained from the Pimela, but it is a poor substitute for the rich olive of Syria.—*Williams' Middle Kingdom, p.* 283.

(4456) ILLICIUM, (illicio, I allure), a genus of Plants, so named in consequence of their very agreeable aromatic fragrance; they belong to the Winter's Bark tribe. These are now generally described as a separate family under the name of *Winteraceæ*, and are distinguished by their dotted leaves and aromatic properties from *Magnoliaceæ*, of which they are sometimes made a section. The genus *Illicium* is characterised by having from 3 to 6 petaloid sepales; 27 petals arranged in several rows below the numerous stamens and pistils. The capsules are disposed in a circular manner, and open upwards; each contains a single shining seed. The species are few in number, but widely distributed. Two are indigenous in Florida; and the others in China and the neighbouring islands. *I. Floridanum* is a red-flowered species, of which the leaves are very fragrant, and the capsules smell of anise, though more faintly than the Chinese species. The bark has been proposed as a substitute for cinnamon and sassafras barks. *I. parviflorum* also, a native of North America, has similar properties, especially in its leaves. The most important species however is *I. anisatum*, or the Aniseed-Tree of China, of which the fruit is exported from Canton, and well known in commerce by the name of Star Anise. In India they are called Badian Khatai, or Chinese Anise. Hence the name Badiane, by which they are chiefly known on the continent of Europe, where they

are more employed than in England; being esteemed, as in the East, for their aromatic and carminative properties. The smell and taste of both the capsule and seed being like that of aniseed, a volatile oil is distilled from them, which may be employed for all the purposes of the oil of aniseed: it is said to give the flavour to Anisette de Bordeaux and to Anisette de Hollande. The Chinese use it in substance both as a condiment and a stimulant medicine, and burn it as incense in their temples. The tree flourishes in China and some of the Philippine Islands, and is found also in Japan, whence Siebold has described a new species. M. Perrotet also mentions that there is an undescribed species at Manilla, which is there called San-ki; that its leaves are mixed with their tea and coffee in the Philippines, and that a liqueur is likewise prepared from its fruit.—*Eng. Cyc.*

(4457) ILLICIUM ANISATUM.

Badian khutaie, ARAB. | Skimmi, JAPAN.
Pa-co-hu-huei-hiam, CHIN. | Badian-i-khotai, PERS.
Anas phool, DUK. | Anaseepoo, TAM.
Badian, HIND.

Star anise, Badian Khutai, or Chinese anise is a native of the countries extending from 23½° to 35 of N. latitude, or from Canton to Japan. The name of *Star* is applied to the fruit from the manner in which they grow, the pods being in small clusters joined together at one end, and diverging in five rays. They are prized for the volatile oil obtained from them, and for their aromatic taste. The barks have a more aromatic flavor than the seeds, but they are not so sweet. In China, their most common use is to season sweet dishes: In Japan they are placed on the tombs of friends and presented as offerings in the temples. They are chiefly exported direct to India, England, and the north of Europe, at the average value of 8½ dollars per picul. in 1850, 695 piculs were exported from Canton valued at 8,200 Spanish dollars. In India they are much used in seasoning curries and flavouring native dishes, and large quantities are used in Europe in the preparation of liqueurs 3,000 piculs of Anise are exported annually from Cambodia, and in 1841, 81 piculs of oil of Aniseed, valued at 11,900 dollars, were exported from Canton.—*Morrison. Simmonds, Faulkner. O'Shaughnessy.* In preparing a spirit of Anise, the Star Anise, may be used instead of common Anise—*Beng. Phar, p.* 412. The capsules constitute in India a rather important article of commerce, and are sold in all the bazars. Large quantities are also used in Europe in the preparation of liqueurs. Both capsules and seeds evolve a powerful odour of anise; the taste is similar, very mild, sweet, and somewhat acidulous. The kernel of the seed is oily. The capsules and seeds abound in an essential oil easily procured by distillation with water; this oil is rather brown, lighter than water, more difficultly congealed than the true aniseed oil, but in other respects exactly of the same properties. Large quantities of the capsules are used in Europe in the preparation of liqueurs. The powdered capsules are used by the Mahomedan practitioners as stimulant carminatives. For the colics of children the essential oil is given with advantage.—*O'Shaughnessy, page* 191.

(4458) IMPATIENS, a genus of plants so called from the sudden and elastic force with which they burst their capsules: hence 'Noli me tangere' is the name of one of the species, another is well known as a highly ornamental annual by the name of Balsam, whence the natural family to which it belongs has been called *Balsaminaceæ*. The genus is especially an East Indian one, though single species extend into Europe, Siberia, and North America, Linnæus was only acquainted with 7 or 8 species; but Dr. Wight, in the "Madras Journal," Vol. ii., states that not less than 100 species are now known, and almost entirely from the mountains of the Peninsula of India and the Himalayas; in those from *Silhet* as far north as the *Sutlej*, and in 30° N. lat., at as great elevations as 7000 feet. They are absent from the plains of India; some are found on the Malabar Coast, little elevated above the sea, but only during the monsoon. Dr. Royle has stated that they are only found in the Himalayas during the rains, and hence inferred that the moisture and moderate temperature, as well as the equability of both during the rainy season, is as favourable to their growth as the heat and moisture of the Peninsula; but Dr. Wight has since ascertained that the species are chiefly found at elevations of 4000 and 4500 feet, in a region where there is moisture combined with a moderate but equal temperature. These facts are important as showing the influence of climate on vegetation; and useful as affording hints and principles for the cultivation of these plants at a lower temperature than is necessary for the plants of the plains from the same latitudes, though great success has been attained in the cultivation of Balsams in Britain.—*Eng. Cyc. Vol* III. *page* 225.

(4459) IMPATIENS BALSAMINA. BALSAM. The common balsam, or touch-me-not, *Noli me tangere* is very common, both wild and cultivated, in Tenasserim.—*Mason.*

(4460) IMPATIENS GLANDULIFERA. Treating them as Indian flowering plants Dr. Riddell says of *Noli me tangere*, that it is so named because the ripe capsules, on being touched, fly open and scatter their seeds. A native of India. The double flowered are most prized. The colours are rose. pink, white, blue, and variegated. When the true colour of the plant from seed can be depended upon, if sown in large beds, or patches, they have a pretty effect in full blossom, and may of course be arranged according to the taste of the cultivator. Is propagated by seed at the commencement of the rains, in

small beds, and then transplanted. After the first blossoms are off they may be cut down, and will throw out fresh shoots, but will not blossom so fine as the first. A rich light loamy soil, with old decayed stable manure. No plant should ever be closer than one foot, especially if the soil is rich, and all lower superfluous leaves and stalks removed from the stems. They thrive well in pots, and during the time they are in blossom look very ornamental placed amongst evergreens.—*Riddell.* Dr. Wight in Icones gives species of Impatiens, albida, 743; campanulata, 744; cuspidata, 741; dasysperma, 742; fasciculata, 748; fruticosa, 966; Gardneriana, 1050; Goughii, 1603; inconspicua, 970 Jerdoniæ, 1602; Kleinii, 884; latifolia, 741, 970 Leschenaultii, 741, 970; modesta, 968; Munronii, 1049; oppositifolia, 883, rivalis, 751; rosmarinifolia, 750; rufescens, 969; scabrida, 323; scapiflora. 967; tomentosa, 745; triphylla, 323, umbelleta, 745; uncinata, 747; viscida, 746.

(4461) IMPERATA CYLINDRICA. THATCH GRASS. Saccharum cylindricum, and Saccharum spontaneum. The Karens in Amherst Province cover their houses with the tall grasses which are so abundant on the Coast, and a few Europeans prefer this thatch to that made from the Nipa. Two different species of grass are used for this purpose both of which were formerly referred to the genus which produces sugar cane. The sugar grass seen in Maulmain, which flowers two or three feet high has been removed since Roxburgh wrote, into the genus Imperata. This is one of the grasses used for thatch, and is often mistaken for *Saccharum spontaneum.*—*Mason.*

Encyc. Brit.

(4463) INDIA RUBBER, This has already been noticed under the head caoutchouc, and its scientific relations will now be noticed. India-rubber is the common name of a vegetable compound which is found in all plants with a milky juice. It is also known by the name of Caoutchouc. The existence of a milky juice in many plants, which flows from them when their tissues are wounded, is a fact that has been familiarly known from time immemorial. It is however only a matter of recent discovery that this milky juice characterises certain families of plants. Although the great majority of plants which yield this juice in abundance are tropical, yet they are not without their European representatives. The Spurges, Dandelion, and Celandine of our roadsides are instances. The families of plants which furnish this milky juice in the greatest abundance are—*Moraceæ*, *Euphorbiaceæ*, *Artocarpaceæ*, *Apocynaceæ*, *Cichoraceæ*, *Papaveraceæ*, *Campanulaceæ*, and *Lobeliaceæ*. This juice, which is called by botanists 'the milky juice,' because it has an appearance similar to milk, has also the physical constitution of that fluid. It is an aqueous liquid charged with soluble matter, in which float globules of a substance insoluble in water, and which are by their tenuity held in suspension in the liquid, but for which they have no affinity, in the same manner as butter is held in suspension by milk. From the difference of the refractive powers of these two substances, each of which taken separately would be colourless or transparent, arise the opacity and white colour of the two: hence the compound is properly called a 'milky' juice.' The analogies which this juice exhibits with the milk of animals and vegetable emulsions are seen in the manner in which it acts when left to itself. Run out into the air, received and preserved in close vessels, it separates itself into two layers, as milk itself would do. The watery part very soon has an insoluble part floating upon it, which collects together and swims at the top as cream swims upon milk, and which forms nearly the half of the entire mass. But with these physical resemblances the analogies cease. That which in milk and in emulsions produced from seeds collects on the surface of the aqueous liquor is, properly speaking, a fatty body, containing oxygen in its composition; while the kind of cream which swims upon the milky juice is a compound of carbon and hydrogen. This substance has long been known to the natives of both the Old and New World, in Hindustan and South America. It was not however till the expedition of the French academicians to South America in 1735 that its properties and nature were made known in Europe by a memoir upon it by M. de la Condamine. This notice excited little attention; and subsequently notices of this substance were sent to the French Academy in 1751 by M. Fresnau, and in 1768 by M. Macquer. At the latter end of the last century and the beginning of the present it was brought into England in small quantities, where, on account of its being used for rubbing out black-lead pencil marks, it acquired the name of India-Rubber. Although after its application to the water-proofing of garments its consumption gradually increased, the importation into the United Kingdom in 1830 appears not to have been more than 50,000 lbs. In 1842 the import of this article had increased to between 700,000 and 800,000 lbs. Up to the present time the consumption of India-Rubber has prodigiously increased; and one port alone in South America is said now to send to Great Britain nearly 4000 cwts. annually. To the large consumption in the United King-

dom must be added that of America, where the application of Caoutchouc has been much more general and successful than even in Great Britain. The particular species of plants which are employed for procuring India-Rubber are very numerous, and it is probable that many yield it which are not yet known to botanists. The tree which supplies most in Continental India is the *Ficus elastica*, a tree belonging to the order *Moraceæ*; it is exceedingly abundant in Assam. All the species of *Ficus* yield Caoutchouc to a greater or less extent in their juices, and even the Common Fig (*Ficus Carica*) of Europe contains it. Species of *Ficus* produce the Caoutchouc brought from Java; and *F. radula*, *F. elliptica*, and *F. prinoides* are amongst those mentioned as affording a portion of that brought from America. Next to the *Moraceæ* the order *Euphorbiaceæ* yields the largest quantity of Caoutchouc. The *Siphonia elastica*, a plant found in Gayalla, Brazil, and extending over a large district of Central America, yields the best kinds of India-Rubber that are brought into the markets of Europe and America. To another order, *Apocynaceæ*, we are indebted for the Caoutchouc which is brought from the islands of the Indian Archipelago. The plant which is the source of this substance in those districts is the *Urceola elastica*, a climbing plant of very rapid growth and gigantic dimensions. A single tree is said to yield, by tapping, from 50 to 60 lbs. annually. Many other plants of this order yield Caoutchouc, and of those given on good authority we may mention—*Callophora utilis* and *Camerania latifolia*, plants of South America; *Vahea gummifera*, in Madagascar; and *Willughbeia edulis*, in the East Indies. To this order belongs the Cow-Tree, or Hya-Hya (*Tabernæmontana utilis*), of Tropical America, which yields a milky juice that is drunk by the natives of the district in which it grows. The Caoutchouc, whilst it is in the tissues of the plant, is evidently in a fluid condition; but, after its separation from the other fluid parts, its consistence becomes changed, and it forms a solid mass similar in its external characters to vegetable albumen. In this state it is dense and hard, but may be separated and rolled out so as to form a sheet resembling leather. It has many interesting and peculiar properties. Insoluble in water and in alcohol, it dissolves in ether, in the sulphuret of carbon, the fat oils, and the liquid carburets of hydrogen. It is soft and elastic at the ordinary temperature, but at the temperature, of 2° above the freezing point it acquires the hardness of wood. A temperature of 100° softens it without altering its form. It then unites with itself with the greatest facility, and two pieces recently cut apart re-unite so as to render it impossible to discover where the junction has taken place. But a higher temperature, approaching 150°, changes it into an adhesive substance, which on cooling does not recover the primitive properties of Caoutchouc. In the state of recent coagulation, and while still in a pulpy condition Caoutchouc possesses a degree of elasticity which admits of its receiving, by means of moulds, the most varied form. The greater part of the Caoutchouc of commerce is obtained by the natives of the countries in which it is produced in the form of shapeless masses, collected at the foot of the tree which has been incised or cut for the purpose of extracting the juice from it, or solidified in a trench made in the earth, and coagulated in this rude mould in voluminous masses, which often resemble the trunk of a large tree. A part of it however possesses other forms which the rude art of the natives attempts to communicate to it. They model with plastic clay figures of animals, imitations of the human foot, and pear-shaped bodies; and then dipping these moulds in the thickened Caoutchouc, and renewing the connection when the first coat is solidified by exposure to the air, they obtain, by breaking the mould and getting it out in fragments through an opening properly arranged, hollow flasks, figures of animals, rough slippers, &c. They thus make Caoutchouc serve for the manufacture of objects for which we ourselves employ animal membranes and leather. India-Rubber is obtained from both the Old and New World. The East Indies supplied the original specimens seen in Europe, and have ever since been a source of supply to the British markets. It comes principally from Java, and is often glutinous, and is less esteemed in commerce than that furnished by the equatorial regions of America. Great quantities of Caoutchouc are imported to Europe from Mexico, from South America, and especially from the province of Para in Brazil. That which comes in the shape of bottles is generally preferred; and when it is pure, and the different coats which comprise it are well united, it may be employed immediately for many purposes. Bnt it often happens that the coats which form the pear-shaped masses are badly united. It then becomes necessary, in order to make use of them, to work it up by a process of kneading, so as to obtain it in a coherent or homogeneous mass. This operation becomes especially indispensable when, as most commonly happens, the Caoutchouc is in large impure masses, and mixed with sand and the debris of vegetable matter. These impurities do not entirely proceed from the moulds made in the earth into which the juice has been allowed to exude, and in which it has been left to thicken and solidify; but their quantity and their presence between the coats of the pyriform masses show that the impurity is mainly to be attributed to fraud. The Caoutchouc thus obtained is not applicable to any use until it has undergone a previous purification. The purification of the Caoutchouc is accomplished by submitting the impure Caoutchouc to the action of cylinders furnished with

teeth turning in opposite directions and with unequal velocities, which cause it to undergo a kind of mastication. By this treatment the Caoutchouc becomes softened without being liquified, and a homogeneous mass is formed which is cut in the form of rectangular blocks, which being again cut, constitute those small parallelopipedons used by draughtsmen to rub out the marks of black lead pencils. This use was in England for a long time the only one to which this substance was applied, but this limited use was far from indicating the extent to which Caoutchouc has been employed in the last thirty years, or the multiplicity of services it has been called upon to perform for sanitary and industrial purposes. To rub out pencilmarks, to form the rude slippers which seemed well adapted to the Indian toilet, but to which a form acceptable in Europe had not been imparted, were in fact the only uses to which Caoutchouc was applied up to 1820. The relations of Caoutchouc to the functions of the plants in which it is found are not understood. Many fallacious views have been offered on this subject. Schulze of Berlin, who has written most extensively on this subject, regarded it as a principle in the juices of plants analogous to the fibrine of the blood, but his views with regard to the milky juice of plants and the laticiferous tissue are now generally allowed to be erroneous. It is not improbable that Caoutchouc is formed as the result of the deoxidation of cellulose, or some other ternary constituent. The chemical composition of Caoutchouc is Hydrogen and Carbon. In what proportion they exist is not known. When distilled, Caoutchouc yields oils which have a composition similar to oil of turpentine—C_5, H_4, or C_{10}, H_8. (*Reports of the Great Exhibition of* 1851, Class XXVIII., by Dr. Lankester: Schleiden, *Principles of Scientific Botany*; Gregory, *Handbook of Organic Chemistry*.) An India Rubbe tree, probably the Ficus elastica, grows to some seventy to ninety feet high. Immense forests of it are found on the west side of the Burampooter, extending along the Meeree and Abor mountains. It is a stately tree—it is said some are 100 feet high. The rubber from this tree has not answered for exporting from India. The expense of making is a mere trifle; but, whether it is owing to the tree having been accustomed to a colder climate, or from some chemical property in the rubber, it cannot bear the heat of a passage to Europe. It becomes a fluid during the voyage. Otherwise, in cold climate, it is equal to other rubbers.—*Bonynge America, page* 258.

(4464) INDIAN CORN. [ZEA,]

(4465) INDIANCRESSES [TROPÆOLACEÆ.]

(4466) INDIAN OX. [BOVIDÆ.]

(4467) INDIAN SHOT. [MARANTACEÆ.]

(4468) INDIANITE. This Mineral occurs in granular masses. It has a hardness 5·5 to 5·5. It scratches glass. The colour is white or grayish; lustre shining; translucent; specific gravity 2.64. It is infusible by the blow-pipe, and gelatinises in acids. It occurs associated with *Garnet, Felspar, Fibrolite, and Hornblende.*

(4469) INDICOLITE. [TOURMALINE.]

Indigo.—The plants which afford Indigo dye are grown chiefly in the East and West Indies, in the middle regions of America, in Africa and Europe, and are mostly species of the genera *Indigofera, Isatis* and *Nerium*. *Indigofera tinctoria* furnishes the chief indigo of commerce, and affords in Bengal, Malabar, Madagascar, the Isle of France, and St. Domingo, an article of middling quality, but not in large quantity. The *Indigofera disperma*, a plant cultivated in the East Indies and America, grows higher than the preceding, is woody, and furnishes a superior dye-stuff. The Guatamala indigo comes from this species. *Indigofera Anil* grows in the same countries, and also in the West Indies. The *Indigofera argentea*, which flourishes in Africa yields little indigo, but it is of an excellent quality. According to Mr. Simmonds *I. pseudotinctoria*, cultivated in the East Indies, furnishes the best of all. *I. glauca* is the Egyptian and Arabian species. There are also the *cinerea, erecta* (a native of Guinea), *hirsuta, glabra*, with red flowers, species common to the East, and several others. The *Wrightia tinctoria*, of the East Indies, an evergreen, with white blossoms, affords some indigo, as does the *Isatis tinctoria*, or Woad, in Europe, and the *Polygonum tinctorium*, with red flowers, a native of China. *Baptisia tinctoria* furnishes a blue dye, and is the wild indigo of the United States.—*Simmonds, p.* 453. Plants of other genera are also employed for obtaining Indigo—as *Wrightia*, (*Nerium*, Roxb.) *tinctoria, Marsdenia tinctoria, Galega tinctoria*, but especially the first two. Dr. Bancroft [vol. i. p. 190] also adduces *Spilanthes tinctoria, Scabiosa suecisa, Cheiranthus fenestralis*; also a species of *Bignonia* and a *Tabernomontana*, on the African coast, with *Amorpha fruticosa* and *Saphora tinctoria*, as all yielding a blue dye, or coarse sorts of indigo.—*Eng. Cyc. Vol.* 3, *page* 228. Indigo of an excellent quality has been obtained in the East from a twining plant, *Gymnema tingens* or *Asclepias tingens*. The *Ruellia* species furnish the well known Room dye of Assam, and the Chinese obtain a blue dye from the Ruellia indigotica, another

species of this genus, as also from the *Isatis indigotica* of Mr. Fortune.

Sources of supply.—Indigo is at present grown for commercial purposes chiefly in Bengal, and the other provinces of that Presidency, from the 20th to the 30th deg. of north latitude; in the Province of Tinnevelly, Cuddapah and the two Arcots in the Madras Presidency; in Java, in the largest of the Philippine islands, in Gautemala, Caraccas, Central America and Brazil. Bengal is, however, the chief mart for indigo, and the quantity produced in other places is comparatively inconsiderable. It is also still cultivated in some of the West India islands, especially St. Domingo, but not in large quantities. Indigo grows wild in several parts of Palestine, but attention seems not to have been given to its cultivation or collection. On most parts of the eastern and western coasts of Africa, it is indigenous; at Sierra Leone, Natal, and other places it is found abundant.—*Simmonds.*

History.—Indigo was known to, and in constant use amongst the Greeks and Romans; and is mentioned especially by Arrian in his *Periplus* as imported by way of Egypt from the country in the vicinity of the Indus. The Venetians, the Portuguese, the Dutch, and subsequently the English imported indigo amongst other articles of the dye and dry-saltery trade. Early in the seventeenth century we find this article becoming one of increasing consumption among the dyers; so much so indeed as to interfere seriously with the trade in woad. So jealous were the authorities of that age of any commercial innovation, of any encroachment upon vested rights, that, in the year 1654, the use of this article, which was called "the Devil's dye," was strictly forbidden within the Austrian dominions, by imperial proclamation. Not content with this extremely conservative measure, the good people of Nuremberg compelled the dyers of their city to take oath each year, that they would employ no indigo in their work. Despite imperial edicts and Nurembergers' oaths, this dye continued to find favour generally throughout Europe; and indifferent as was the article produced in those days, the trade became one of considerable value until the close of the seventeenth century, when they were driven from the European markets by the active competition of the West Indian planters and the colonists of America. Subsequently, however, when the States declared their independence, and the culture of the West Indian plant was neglected for other articles, the E. I. Company resumed their dealings in it, and by giving all the encouragement in their power, not only to native but to European planters, they succeeded, after a number of years, in establishing the manufacture of indigo on such a firm footing, that the Bengal article now ranks the highest in public estimation, having fairly driven all competition from the field. It is highly problematical, however, if the manufacture of indigo in British India would have arrived at its present state of prosperity but for the spirit evinced by the Directors of the East India Company, who, in the teeth of losing markets, continued to make extensive purchases of the article from the European planters, shipping their investment to a certain loss, until, after a series of years, the agriculture of the plant, and the chemistry of the manufacture, became so thoroughly investigated, and received so many improvements, as to place the trade beyond the necessity for any further fostering. The first, or London East India Company, carried on a very profitable trade in this dye for upwards of a century; purchasing it from the native makers at about a shilling the pound, and selling it at five times that price. Between the years 1664 and 1694 their imports of the article into Great Britain did not exceed 60,000 lbs. annually. In those days the seat of the native manufacture of indigo of the finest quality was at Agra. Lahore contributed a good article, as did the Golconda country. The inferior sorts came from Surat, Berampoor, Indore, Oude, and Bengal. At the present time the finest indigo is manufactured in the Bengal presidency, where it has been found that both soil and season are highly favourable to the culture and development of the plant. A considerable quantity, about 4,000 chests, is produced in and about the vicinity of Madras, some of which is of superior quality. Towards the close of the last century, say in 1786, the shipments of indigo to Great Britain amounted to 245,000 lbs. Shortly after that period the attention and capital of English cultivators were turned towards the article, as already related; and we find the results of this enterprise in the statement of exports to all parts of the world, but mainly to England: this gives the quantity for 1795 as 2,644,710 lbs.; for 1799, at 4,571,420 lbs.; for 1810, at 5,520,874 lbs.; and for 1848-9, at 9,920,000 lbs., of which three-fourths were to Great Britain.—*Capper's Three Presidencies, p.2.* The quality of indigo depends upon the species of the plant, its ripeness, the soil and climate of its growth, and the mode of manufacture. The East India, and Brazilian indigo arrives in England packed in chests, the Guatemala in ox-hides, called serons. The indigo imported from the western hemisphere was for some time considered superior in quality to that of the East. Its cultivation, however, has been neglected, and the Bengal indigo is preferred at present to any imported from South America, where it is now only cultivated by the Brazilians and Colombians. If proper attention were paid to the cultivation of the plant, and to the preparation of the dye, it is very likely part of that important trade would be brought back. It thrives best in a moist climate, and the interior of Guiana, chiefly newly-cleared

land, would be well adapted for it. The late Mr. Dunlop ("Travels in Central America") gives an interesting description, which, at the risk of repetition in some points, I shall give entire. "Several vessels generally arrive at the Union from South America at the time of the periodical fairs, where nearly all the indigo (the only produce of any importance), is disposed of; formerly it reached 10,000 bales, but at present it does not at most exceed 3,000 bales of 150 lbs. each. The indigo well known in Europe by the name of Guatemala indigo, was never cultivated in that province (in the same manner as not a grain of the Honduras cochineal is grown there), being entirely grown in the state of San Salvador, in the vicinity of San Miguel, San Vicenti, and the city of Salvador, with the exception of a small quantity of very superior quality grown in the state of Nicaragua, and a few bales in Costa Rica, which is all consumed in the State. Under the government of Spain, the produce of the state of San Salvador alone had reached 10,000 bales, and that of Nicaragua 2,000; the produce of San Salvador in 1820 two years before its independence, being 8,323 bales. But since 1822 the annual produce had gradually declined, and in 1846 it did not exceed 1,000 to 1,200 bales, nearly all the indigo estates being abandoned, partly, no doubt, from the great fall in the price of the article, but more on account of the impossibility of getting laborers to work steadily. The plant cultivated in Central America for the manufacture of indigo, is the triennial plant, supposed to be a native of America; but there is also an indigenous perennial plant, abounding in many parts of Central America, which produces indigo of a very superior quality, but gives less than half the weight which is produced by the cultivated species. The ground for sowing the indigo seed is prepared in April, — a piece of good forest land near one of the towns being selected, a part is cut to make a rude fence, and the remainder burnt, which is easily accomplished, as everything is very dry at that season; and the ground is afterwards scratched with two sticks, fastened crosswise, to resemble somewhat the shape of a plough, and the seed scattered over it by hand. The rainy season always commences early in May, and the indigo is ready for cutting about the middle of July, taking about two and a half months to come to perfection. The growing crop somewhat resembles lucerne, and is in the best state for making indigo, when it becomes covered with a sort of greenish farina. The crop of the first year is small, and sometimes not worth manufacturing; that of the second year is the best, and the third is also very good, if it has been carefully weeded; but many indigo fields have lasted more than ten years without being re-sown, as the seed which falls naturally springs up again, and where the land is good yields nearly as large a crop as a new-sown field. When the plant is ready for manufacturing, a number of men are collected, each of whom is either provided with, or brings his own mule or horse, if he has one. Two men always go together, cut the plant, then about the height of full-grown red clover, and take it to the vats, which are large tanks made of brick and lime, holding at least 1,000 gallons, and some as much as 10,000. Into these the plant is thrown till they are nearly full, when weights are put above it to prevent its floating, and the vats filled with water till it covers the mass of the indigo plant. After remaining from twelve to twenty-four hours according to the state of the plant, weather, and other circumtances (the time required being determined by the color which the water assumes), the herb is taken out, and the water beaten with paddles in the very small vats, and by a wheel suspended above and turned by men or horses in the larger ones, till it changes from a green color, which it has acquired ere the removal of the herb, to a fine blue, when it is allowed to stand for some hours, till the coloring matter has settled to the bottom of the tank, a process which is generally hastened by throwing in an infusion of certain herbs to facilitate its settlement, or as the natives term it curdle (*cuajar*) the colored water. As soon as all the color has settled, the water is drawn off, and the blue, which is of the consistency of thick mud, is taken out of the vat and spread upon cotton, or coarse woollen cloth, and dried in the sun. The color in a great measure depends upon removing the herb exactly at the proper time, and upon properly beating the water, neither too long nor too short. Unless these processes are properly performed, the indigo will not be of first-rate quality; but some estates will never produce the best indigo, whatever care may be bestowed on the manufacture. A *mansana*, of 100 yards square, which is nearly two British statute acres, produces generally about 100 to 120 lbs. of indigo, the carriage and cutting of the herb costing about twenty dollars, and the cleaning of the field and all other expenses connected with it, including the manufacture of the indigo, about as much more. The indigo of Central America is not put into moulds when drying, as that of Bengal, but is allowed to remain in the rough shape in which it dries, and without further preparation is ready for baling and exportation. The bales are generally made up in 150 lbs. each, and the quality is classed by numbers, from 1 to 9; Nos. 1 to 3 being of the quality called *cobres* in Europe; Nos. 4 to 6 of that called *cortes*, and Nos. 7 to 9 of that called *flores*; Nos. 1 to 6 do not at present pay the expenses of manufacture, and are never intentionally made. No doubt, with a little more skill in the manufacture, the whole might, as in Bengal, be made of the quality called *flores*; but such improvements cannot be expected till a new

race of people inhabit Central America. At present about one half of the indigo produced is under No. 7, and as the cultivation is said not to pay at the present prices—and, indeed, hardly can be supposed to compete with Bengal, a country where labor is so much cheaper, and capital abundant—it is probable, that the cultivation will shortly be entirely abandoned, unless the price should again rise in Europe." In 1846, 31,933 lbs. of indigo were exported from Angostura. The following particulars were contributed to Simmonds' "Colonial Magazine," by the late Dr. Edward Binns, of Jamaica :— The species generally cultivated is the *I. tinctoria*, which requires a rich moist soil and warm weather. The seed, which is at first sight not unlike coarse gunpowder, is sown three or four inches deep, in straight lines, twelve or fifteen inches apart. The shoots appear above ground in about a week; at the end of two months the plant flowers, when it is fit for cutting, which is done with a pruning knife. It must be mentioned that great care is requisite in weeding the indigo field when plants first shoot through the earth. In the State of St. Salvador, large vats made of mahogany, or other hard wood, are constructed for the reception of the plant, where it is allowed to undergo maceration and fermentation. In a short time the water becomes greenish, and emits a strong pungent smell, while carbonic acid gas is freely evolved. In about twenty-four hours it is run off into large flat vessels, and stirred about until a blue scum appears, when additional water is added, and the blue flakes sink to the bottom. The supernatant water has now acquired a yellowish tinge, when it is run off carefully, and the blue deposit or sediment put into bags to drain. It is subsequently dried in the shade, or sometimes in the sun, then placed in cotton bags and carried to the indigo fair, or forwarded to the city of Guatemala. The East Indian mode of manufacturing the indigo differs materially, and many suppose it preferable to the Salvador. It consists in *steaming* the fermented mass in large pipes enclosed in huge boilers. I am inclined to believe this to be the most economical, if not the best way of manufacturing indigo. From Guatemala alone, it is computed that from 6,000 to 8,000 serons of indigo are exported annually; while San Miguel, Chalatenaugo, Tejulta, Secatecolnea, St. Vincent, Sensuntepepe, not only, it is said, produce a larger quantity, but the four-last mentioned places have the advantage as to quality. The *Belize Advertiser* stated some time since, that the value of this dye from one State in 1830 produced 2,000,000 dollars, the minimum of an immense sum which has been most unjustly and unwisely wrested from the people of Jamaica, and the West India islands. Bridges ("Annals of Jamaica," p. 584, Append.), speaking of the vast returns of an indigo plantation, says, "The labour of a single negro would often bring to his owner £30 sterling per annum clear profit,—a sum which was at the time the laborer's highest price. It continued the *staple* of Jamaica till an intolerable tax oppressed it, while its price was lowered by the competition of other colonies. Its cultivation immediately declined throughout them all, but nowhere so rapidly as here. The financial error was quickly discovered,—a remedy was attempted by a bounty; but it came too late, the plantations were thrown up, and the planters, attracted by the temporary gain, abused the tardy boon, by introducing, as of their own growth, large quantities of foreign indigo." As Bridges may be said in this passage to be merely a commentator on Edwards, who has entered more largely upon the subject, I shall condense from the latter, statements connected with the manufacture and decay of this branch of industry, once the staple of Jamaica. Edwards ("West Indies," vol. ii., p. 275, 2nd edition) reckons three kinds of indigo—the wild, Guatemala, and French. The first is the hardest, and the dye extracted from it of the best quality as regards colour and grain; but one or other of the two species is commonly preferred by the planter, as yielding a greater return. Of these the French surpasses the Guatemala in quantity, but yields to it in fineness of grain and beauty of color. The indigo thrives almost on any land, though the richest soils produce the most luxuriant plants, and the longest dry weather will not kill it. The cultivation and manufacture our author thus describes :—"The land being prepared, trenches, two or three inches in depth, are made by the hoe. These are ten or twelve inches asunder. The seeds are then strewed in the trenches by the hand, and slightly covered with mould. When the plants shoot, they are carefully weeded, and kept constantly clean, until they rise high enough to cover the ground. A bushel of seed is sufficient for four or five acres. The best season for planting is March; but if the land be good, it may be sown at any time, and in three months the plants attain maturity. In seasonable situations, they have four cuttings in the year. The subsequent growths from the plants ripen in six or eight weeks; but the produce diminishes after the second cutting, so that the seeds should be sown every second year. A species of grub, or worm, which infests the plant on the second year is avoided by changing the soil; or, in other words, by a rotation of crops. The produce per acre of the first cutting is about 60 lbs. It is nearly as much in North America; but when the thermometer falls to sixty, the returns are very uncertain, that degree of heat being too low for the necessary vegetation, maceration, and fermentation. The yieldings for the subsequent cuttings somewhat diminish; but in Jamaica and St. Domingo, if the land is new, about 300 lbs. per acre of the second quality may be expected annually from all the cuttings

together; and four negroes are sufficient to carry on the cultivation of five acres, besides doing other occasional work, sufficient to reimburse the expenses of their maintenance and clothing." The process for obtaining the dye, according to the same author, was conducted through the means of two cisterns, the one elevated above the other, in the manner of steps. The higher, which was also the longer, was named the *sleeper*—its dimensions sixteen feet square and two and a half in depth. The second, into which the fluid was discharged, was called the *battery;* it was about twelve feet square, and four and a half in depth, These cisterns were of stone: but strong timber answered remarkably well. There was also a lime-vat, six feet square and four-feet deep, the plug of which was at least eight inches from the bottom. This was for the purpose of permitting the lime to subside, before the lime-water was withdrawn. The plants then being ripe, or fit for cutting, were cut with reaping-hooks, or sickles, a few inches from the ground—six was the minimum—and placed by strata in the *sleeper*, until it was about three parts full. They were then pressed with boards, either loaded with weights or wedged down, so as to prevent the plants from floating loosely: and as much water was admitted as they would imbibe, until it covered the mass four or five inches deep. In this state it was allowed to ferment until the water had extracted the pulp. To know when this had been thoroughly effected, required extreme attention and great practical knowledge; for if the fluid were drawn off too soon, much of the pulp was left behind; and if the fermentation continued too long, the tender tops of the plants were decomposed, and the whole crop lost. When the tincture or extract was received in the battery, it was agitated or churned until the dye began to granulate, or float in little flakes upon the surface. This was accomplished at one period in Jamaica by paddles, worked by manual labor, and, in the French islands, by buckets or cylinders, worked by long poles; but subsequently—that is, at the time Edwards wrote—convenient apparatus was constructed, the levers of which were worked by a cog-wheel, kept in motion by a horse or mule. When the fluid had been churned for fifteen or twenty minutes, a small quantity was examined in a cup or plate, and if it appeared curdled, or coagulated, strongly impregnated lime-water was gradually added, not only with a view to promote separation, but to prevent decomposition. Browne remarks ("Civil and Nat. Hist. of Jamaica," art. "Indigo"), the planters "must carefully distinguish the different stages of this part of the operation also, and attentively examine the appearance and colour as the work advances,—for the grain passes gradually from a greenish to a fine purple, which is the proper color when the liquor is sufficiently worked,—too small a degree of agitation leaving the indigo green and coarse, while too vigorous an action brings it to be almost black." The liquor being then, as we shall suppose, properly worked, and granulation established, it was left undisturbed until the flakes settled at the bottom, when the liquor was drawn off, and the sediment (which is the indigo) placed in little bags, to drain, after which it was carefully packed in small square boxes, and suffered to dry gradually in the shade. Such is the account, nearly word for word, which Edwards gives of the mode of manufacturing indigo. I shall now quote his remarks upon the outlay and gain upon the article *verbatim*.—"To what has been said above of the nature of the plant suiting itself to every soil, and producing four cuttings in the year, if we add the cheapness of the buildings, apparatus, and labor, and the great value of the commodity, there will seem but little cause for wonder at the splendid accounts which are transmitted down to us concerning the great opulence of the first indigo-planters. Allowing the produce of an acre to be 300 lbs., and the produce no more than 4s. per pound, the gross profit of only twenty acres will be £1,200, produced by the labor of only sixteen negroes, and on capital in land and buldings scarce deserving consideration." Yet, notwithstanding this statement, the author informs us afterwards that he knew, in the course of eighteen years' residence in the West Indies, upwards of twenty persons who tried to re-establish indigo manufactories, but failed. This appears strange, since it is plain that what has once been done can be done again, but especially in the manufacture of an article requiring a capital so very small in proportion to the profits as almost to tempt the most cautious and the most timid man to embark in it. I quote the following passage from the same author, for the purpose of showing the very loose manner in which statements are made on the authority of others, who are as incompetent to decide the merits of a question as the party himself chronicling their opinion. Speaking of the twenty unfortunate indigo-planters, our author thus writes —"Many of them were men of foresight, knowledge and property. That they failed is certain; but of *the causes of their* FAILURE *I confess I can give no satisfactory account.* I was told that disappointment trod close upon their heels at every step. At one time the fermentation was too long continued, at another the liquor was drawn off too soon: now the pulp was not duly granulated, and now it was worked too much. To these inconveniences, for which practice would doubtless have found a remedy, were added others of a much greater magnitude—the mortality of the negroes, from the vapour of fermented liquor (an alarming circumstance, that, I am informed, both by the French and English planters, constantly attends the process), the

failure of the seasons, and the ravages of the worm. These, or some of these evils, drove them at length to other pursuits, where industry might find a surer recompense."—(p. 283.) The fallacy of much of this requires no comment, as it must strike even the most careless reader,—for if the so-called indigo-growers did not know the process of manufacturing the commodity, then it could not be surprising that they failed. Thus the cause of their failure required no comment, and no explanation. Were a ploughman taken from the field and placed at the helm of a ship, and the vessel in consequence wrecked, would any one be astonished but at the folly of those who placed him there? This was the case with the indigo-growers,—they attempted what they did not understand, and, consequently, lost their labor and their money. The mortality of the negroes employed, stated as another reason for abandoning the attempt, requires a somewhat more lengthy notice. I can briefly say, that I have learned that in the Central States of America, deaths among indigo-laborers are not more frequent than in other branches of tropical industry; and I never heard or have read that the *original* growers complained of the mortality attending the progress. The truth is, that this statement is not founded on fact. There is nothing whatever in the manufacture of indigo, either in the cultivation or the granulation, or even the maceration and fermentation of the plant, which is directly or indirectly, *per se*, injurious to human life. I have certainly never seen the indigo plant macerated on a large scale; but I have myself steeped much of it in water, and allowed it even to rot, and found nothing in the mass differing in any marked degree from decomposed vegetable matter. It seems to me that this idea of the manufacture of indigo being especially inimical to human life, is as unfounded as the belief, even by Humboldt, up to a very recent period, that none of the Cerealia would grow in tropical climates. In conversing with an old gentleman in Jamaica, some twelve years since, who had tried the manufacture of indigo, and with every prospect of success, but abandoned it, as he confessed, for the cultivation of the sugar cane, since it was then more profitable, he suggested the solution, that as the manufacture was light work, probably aged and debilitated, in place of youthful and vigorous slaves, were too frequently employed in the process—hence the mortality. This may be correct to a certain extent; but I am also inclined to think that another cause of mortality might be found in the mode and manner in which the negro was fed and clothed, and not because aged persons were exclusively engaged in the manufacture. I believe I may state, without fear of contradiction, that the real cause of the decline and consequent abandonment of the indigo plant was the monstrous duty levied upon it by the

English government. Indeed, this has been already stated in the extract from Bridges; while the cause of the failure of the attempt to renew it, over and above the reasons we have given, is the greater temptation to embark capital in sugar plantations,—the West Indies enjoying a monopoly in this article, while they had competitors in the Southern States of America in the other. We have, therefore, no hesitation in saying, that with a trifling capital, under prudent management, indigo might be cultivated to a very great extent, and with considerable profit, even now in Jamaica. But the adventurer is not to expect to count his gains, as the original growers did by thousands; he must be content with hundreds, if not fifties; for at the present day every branch of industry is laden with difficulties, encumbered by taxation, and obstructed by competition. There are two objections, however, which I have not removed,—I allude to "the failure of the seasons and the ravages of the worm." Very little need be said to combat these. Seasons are mutable, and the same Heaven that frowns this year on the labors of the husbandman, may smile the next; while a remedy for the "ravages of the worm" may be found in the mutation of the soil, the destruction of the grub, or the rotation of crops,—accessories to success which seem not to have entered into the vocabularies of the twenty pseudo indigo-growers, "many of them men of knowledge, foresight and property." The following passage from Bryan Edwards will corroborate much that I have endeavoured to enforce. It furnishes not only a solution which has been hinted at before, of the enigma why indigo ceased to be cultivated in Jamaica, but also *an incentive* to re-introduce the culture. He says (p. 444), "It is a remarkable and well known circumstance, after the cultivation of indigo was suppressed by an exorbitant duty of near £20 the hundred-weight, Great Britain was compelled to pay her rivals and enemies £200,000 annually for this commodity, so essential to a great variety of her most important manufactures. At length, the duty being repealed, and a bounty some time after substituted in its place, the States of Georgia and South Carolina entered upon, and succeeding in the culture of this valuable plant, supplied at a far cheaper rate than the French and Spaniards (receiving too our manufactures in payment) not only the British consumption, but also enabled Great Britain to export a surplus at an advanced price to foreign markets."—It is therefore plain that the manufacture of indigo was lost to Jamaica, not from any difficulty in growing the plant, or from any loss of life attending the process of manufacturing it, but from the ruinously heavy duty of £20 the hundred-weight—and that now, when no duty exists, it might be again cultivated with great advantage. The cultivation of indigo has been repeatedly attempted

in Cuba, but never with much success; although the shrub called the Xiquilite, from which it is extracted, grows wild in several districts of the island, but more especially towards the eastern extremity. The first *anileria*, or manufactory of indigo, was established in 1795, under the patronage of the *Ayentamento* of the Havana, who made an advance of 3,500 dollars, without interest, to the party engaging in the speculation, in order to encourage the enterprise; but the undertaking proved unsuccessful, and the same fate has befallen every subsequent attempt to introduce this branch of industry. In 1827, the whole produce amounted only to 56 arobas. In 1837 the imports of indigo greatly exceeded the exports; the former having amounted to 121,350 lbs., and the latter to 82,890 lbs. In 1833, 5,184 lbs. reached the United Kingdom from the Havana, and in 1843, 62,675 lbs. In 1826, British Honduras exported 358,552 lbs.; in 1830, 2,650 serons; in 1844, 1,247 serons; and in 1845, 1,052 serons. The indigo shrub is one of the most common bushes in Trinidad, where it grows wild on almost all the indifferent soils. In 1783, there were several plantations and manufactories of indigo established in Trinidad: these were subsequently abandoned, on account of a supposition that they were unhealthy. Prior to 1783, the colonists had a kind of simple process by which they extracted sufficient coloring matter to serve domestic consumption. This process is at present unknown, hence all the indigo used there is imported from Europe, although the plant from which it can be made vegetates in every direction. In 1791 Hayti imported 930,016 lbs. of indigo, while in 1804 the exports had dwindled to 35,400 lbs. Indigo, as I have already stated, was once a most important crop in South Carolina, some attention has recently again been given to it by an individual or two in Louisiana, and the enterprise is said to promise success: enough might undoubtedly be raised in the United States to supply the home market. Some indigo produced at Baton Rouge was pronounced to have been equal to the best Caraccas, which sells at two dollars per pound; and the gentleman who cultivated it remarks, that one acre of ground there, well cultivated, will yield from 40 to 60 lbs.; that it requires only from July to October for cultivating it; that there is not connected with it one-third of the expense or time that is generally required for the cultivation of cotton. I take the following from Smyth's "Tour in the United States." "This plant is somewhat like the fern when grown, and when young is hardly distinguishable from lucern grass, its leaves in general are pinnated, and terminated by a single lobe; the flowers consist of five leaves, and are of the papilionaceous kind, the uppermost petal being longer and rounder than the rest, and lightly furrowed on the side, the lower ones are short and end in a point; in the middle of the flower is formed the style, which afterwards becomes a pod containing the seeds. "They cultivate three sorts of Indigo in Carolina, which demand the same variety of soils. First, the French or Hispaniola indigo, which striking a long tap root will only flourish in a deep rich soil, and therefore, though excellent in sort, is not so much cultivated in the maritime parts of the State, which are generally sandy, but it is produced in great perfection one hundred miles backwards; it is neglected too on another account, for it hardly bears a winter so sharp as that of Carolina. The second sort, which is the false Guatemala, or true Bahamas, bears the winter better, is a more tall and vigorous plant, is raised in greater quantities from the same compass of ground, is content with the worst soil in the country, and is therefore more cultivated than the first sort, though inferior in the quality of its dye. "The third sort is the wild indigo which is indigenous here; this, as it is a native of the country, answers the purposes of the planter best of all, with regard to the hardiness of the plant, the easiness of the culture, and the quantity of the produce. Of the quality there is some dispute not yet settled amongst the planters themselves; nor can they distinctly tell when they are to attribute the faults of their indigo to the nature of the plant, to the seasons, which have much influence upon it, or to some defect in the manufacture. "The time of planting the indigo is generally after the first rains succeeding the vernal equinox; the seed is sown in small straight trenches, about eighteen or twenty inches asunder: when it is at its height, it is generally eighteen inches tall. It is fit for cutting, if all things answer well, in the beginning of July. "Towards the end of August a second cutting is obtained, and if they have a mild autumn, there is a third cutting at Michaelmas. The indigo land must be weeded every day, the plants cleansed from worms, and the plantation attended with the greatest care and diligence. About twenty-five hands may manage a plantation of fifty acres, and complete the manufacture of the drug, besides providing their own necessary subsistence and that of the planter's family. "Each acre yields, if the land be very good 60 or 70 lbs. weight of indigo: at a medium the produce is 50 lbs. This however, is reckoned by many skilful planters but a very indifferent crop. "When the plant is beginning to blossom it is fit for cutting, and when cut, great care ought to be taken to bring it to the steeper without pressing or shaking it, as great part of the beauty of the indigo depends upon the fine farina, which adheres to the leaves of this plant. The apparatus for making indigo is inconsiderable and not expensive, for besides a pump, the whole consists only of vats and tubs of cypress wood, common and cheap in this

country. "The indigo, when cut, is first laid in a vat, about twelve or fourteen feet long and four feet deep, to the height of about fourteen inches, to macerate and digest; then this vessel, which is called the *steeper*, is filled with water; the whole having lain from about twelve to sixteen hours, according to the weather, begins to ferment, swell, rise, and grow sensibly warm. At this time spars of wood are run across, to mark the highest point of its ascent; when it falls below this mark, they judge that the fermentation has attained its due pitch, and begins to abate; this directs the manager to open a cock, and let off the water into another vat, which is called the *beater*; the gross matter that remains in the first vat is carried off to manure the ground, for which purpose it is excellent, and now cuttings are put in, as long as the harvest of the weed continues. When the water, strongly impregnated with the particles of indigo, has run into the second vat or beater, they attend with a sort of bottomless buckets, with long handles, to work and agitate it, when it froths, ferments, and rises above the rim of the vessel that contains it. To allay this violent fermentation, oil is thrown in as the froth rises, which instantly sinks it. When this beating has continued for twenty, thirty, or thirty-five minutes, according to the state of the weather (for in cool weather it requires the longest continued beating), a small muddy grain begins to be formed; the salts and other particles of the plant united, dissolved and before mixed with the water, are now reunited together, and begin to granulate. To discover these particles the better, and to find when the liquor is sufficiently beaten, they take up some of it from time to time on a plate, or in a glass; when it appears in a hopeful condition, they let loose some lime water from an adjacent vessel, gently stirring the whole, which wonderfully facilitates the operation; the indigo granulates more fully, the liquor assumes a purplish color, and the whole is troubled and muddy; it is now suffered to settle: then the clearer part is permitted to run off into another succession of vessels, from whence the water is conveyed away as fast as it clears on the top, nntil nothing remains but a thick mud, which is put into bags of coarse linen. These are hung up and left for some time until the moisture is entirely drained off. "To finish the drying, this mud is turned out of the bags, and worked upon boards of some porous timber, with a wooden spatula: it is frequently exposed to the morning and evening sun, but for a short time only; and then it is put into boxes or frames, which is called the curing, exposed again to the sun in the same cautious manner, until, with great labor and attention the operation is finished, and the valuable drug fitted for the market. The greatest skill and care is required in every part of the process, or there may be great danger of ruining the whole; the water must not be suffered to remain too sho or too long a time, either in the steeper or bea er; the beating itself must be nicely manage so as not to exceed or fall short; and in the cu ing the exact medium between too much or to little drying is not easily attained. Nothing bu experience can make the overseers skilful i these matters. There are two methods of try ing the goodness of indigo; by fire and b water. If it swims it is good, if it sinks i is inferior, the heavier the worse; so if i wholly dissolves in water it is good. Anothe way of proving it, is by the fire ordeal; if i entirely burns away, it is good, the adulteration remain untouched." Indigo to the extent c 220,000 lbs. per annum is grown in Egypt. Th leaves are there thrown into earthen vessels which are buried in pits and filled with water heat is applied, and the liquid is boiled away un til the indigo becomes of a fit consistence, whe it is pressed into shape and dried. Many Ar menians have been invited from the East Indie to teach the fellahs the best mode of preparation and, in consequence, nine indigo works hav been established belonging to the government The indigo plant is found scattered like a wee abundantly over the face of the country in th district of Natal, Eastern Africa. It is said tha there are no less than ten varieties of the plan commonly to be met with there. Mr. Blain submitted, in 1848, to the Manchester Chambe of commerce, a small specimen of this dye-stuff which had been extracted by a rude process fron a native plant, which was pronounced by gooc authority to be of superior quality, and worth 3s. 4d. per pound. Mr. W. Wilson, a settler a Natal, in a letter to the editor of the *Nata Witness*, thus speaks of the culture:—"My at tention was first forcibly drawn to the cultivation of indigo by some seed imported by Mr. Kinlock from India. This seed, on trial, I found to grow luxuriantly; and after a few experiments I suc ceeded in manufacturing the dye. The success which thus attended my first attempts has en couraged me to try indigo planting on a more extensive scale. For this purpose I am allow ing all the plants of this season to run to seed and intend to plant equal quantities of Benga and native indigo. While my attention was engaged in these preliminary experiments, I ob served that the country abounded in a variety o species of indigo, and by a series of experiments found it rich and abundant, and have since learnt that it is known and in use among the na tives, and called by them Umpekumbeto. This of course induced further inquiry, and on con sulting different works I find that the Cape of Good Hope possesses more species of indigo than the whole world besides. Now I take it for granted that if Providence has placed these materials within our reach, it was evidently in tended that we should, by the application of in-

dustry, appropriate them to our use. It becomes, then, a matter of necessity that indigo must thrive, this being its native soil and climate; and the experiments I have successfully made, go to support me in the opinion that the cultivation of indigo will bring an ample reward. Indeed it seems contrary to the laws of nature that it should be otherwise. I have obtained from the 140th part of an acre the proportion of 300 lbs. of indigo per acre. That the plant will cross successfully, I have also ascertained."

Cultivation in India.—During the nine years which preceded the opening of the trade with India in 1814, the annual average produce of indigo in Bengal, for exportation, was nearly 5,600,000 lbs. But since the ports were opened, the indigo produced for exportation has increased fully a third, the exports during the sixteen years ending with 1829-30, being above 7,400,000 lbs. a year. The consumption in the United Kingdom has averaged, during the last ten years, about 2,500,000 lbs. a year. In 1839 40 the export of indigo from Madras amounted to 1,383,808 lbs. A small quantity is also exported from the French settlement of Pondicherry. In 1837 the export from Manilla amounted to about 250,000 lbs. The export from Batavia in 1841 amounted to 913,693 lbs. and the production in 1843 was double that amount. The annual exports of indigo, from all parts of Asia and the Indian Archipelago, were taken by M'Culloch, in 1840, to be 12,440,000 lbs. The imports are about 20,000 chests of Bengal, and 8,000 from Madras annually, of which 9,000 or 10,000 are used for home consumption, and the rest re-exported. The total crop of indigo in the Bengal Presidency has ranged, for the last twenty years, at from 100,000 to 172,000 factory maunds; the highest crop was in 1845. The factory maund of indigo in India is about 78 lbs. In the delta of the Ganges, where the best and largest quantity of indigo is produced, the plant lasts only for a single season, being destroyed by the periodical inundation, but in the dry central and western provinces, one or two *ratoon* crops are obtained. The culture of indigo is very precarious, not only in so far as respects the growth of the plant from year to year, but also as regards the quantity and quality of the drug which the same amount of plant will afford in the same season. The fixed capital required, as I have already shown, in the manufacture of indigo, consists simply of a few vats of common masonry for steeping the plant, and precipitating the coloring matter; a boiling and drying house, and a dwelling for the planter. Thus a factory of ten pairs of vats, capable of producing, at an average, 12,500 lbs. of indigo, worth on the spot £2,500, will not cost above £1,500 sterling. The buildings and machinery necessary to produce an equal value in sugar and rum, would probably cost about £4,000. The indigo of Bengal is divided into two classes, called, in commercial language, Bengal and Oude; the first being the produce of the southern provinces of Bengal and Bahar, and the last that of the northern provinces, and of Benares. The first class is in point of quality much superior to the other. The inferiority of the Oude indigo is thought to be more the result of soil and climate, than of any difference in the skill with which the manufacture is conducted. The indigo of Madras, which is superior to that of Manila, is about equal to ordinary Bengal indigo. The produce of Java is superior to these. Large quantities of indigo, of a very fine quality, are grown in Scinde. I have to acknowledge the receipt, from the Indian Government, of an interesting collection of documents on the culture and manufacture of indigo in Upper Scinde. The papers are chiefly from the pen of Mr. Wood, Deputy Collector of Sukkur, though there are several others, perhaps of much value, from various other of the revenue officers of Scinde. Mr. Wood is of opinion that Scinde is much better suited than Bengal for the production of this dye-stuff—the alluvial soil on the banks of the Indus is equal in richness to that on those of the Ganges, and the climate seems equally well suited for the growth of the plant. But in two years out of three, the crops of the Bengal planter are injured by excessive inundations, while the work of gathering and manipulation is necessarily performed during the rainy season, under the greatest imaginable disadvantages. In Scinde, on the other hand, the inundation of the river is produced almost solely from the melting of the snows in the Himalayas, and it is not liable to those excessive fluctuations in amount, or that suddenness in appearance peculiar to inundations chiefly arising from falls of rain. The Ganges sometimes rises ten feet in four-and-twenty hours, and at some part of its course its depth is at times forty feet greater during a flood than in fair weather, while the Indus rarely rises above a foot a day, its extreme flood never exceeding fifteen feet, the limits and amount of the inundation being singularly uniform over a succession of years. Moreover, as rain hardly ever falls in Scinde, and when it does so, only continues over a few days, and extends to the amount of three or four inches, no danger or inconvenience from this need be apprehended. Mr. Wood mentions that hemp may be grown in profusion on the indigo grounds, and that were the production of the dye once introduced, it would bring hundreds of thousands of acres now barren into cultivation, and secure the growth or manufacture of a vast variety of other commodities for which the country is eminently fitted. An experimental factory might, it is believed, be set up for from two to three thousand pounds, but this appears to be an amount of adventure from

which the Government shrinks. The districts of Kishnagar, Jessore and Moorshedabad, in Bengal ranging from 88 to 90 degs. E. latitude, and 25½ to 24 degs. N. longitude, produce the finest indigo. That from the districts about Burdwan and Benares is of a coarser or harsher grain. Tirhoot, in latitude 26 degs., yields a tolerably good article. The portion of Bengal most propitious to the cultivation of indigo, lies between the river Hooghly and the main stream of the Ganges. In the East Indies after having ploughed the ground in October, November, and the beginning of December, they sow the seed in the last half of March and the beginning of April, while the soil being neither too hot nor too dry, is most propitious to its germination. A light mould answers best; and sunshine, with occasional light showers, are most favorable to its growth. Twelve pounds of seed are sufficient for sowing an acre of land. The plants grow rapidly, and will bear to be cut for the first time at the beginning of July; nay, in some districts so early as the middle of June. The indications of maturity are the bursting forth of the flower buds, and the expansion of the blossoms; at which period the plant abounds most in the dyeing principle. Another indication is taken from the leaves, which, if they break across when doubled flat, denote a state of maturity. But this character is somewhat fallacious, and depends upon the poverty or richness of the soil. When much rain falls, the plants grow too rapidly, and do not sufficiently elaborate the blue pigment. Bright sunshine is most advantageous to its production. The first cropping of the plants is the best; after two months a second is made; after another interval a third, and even a fourth; but each of those is of diminished value.

Culture in India.—For the following excellent account of the modes of culture, and practice, &c., in Bengal, and other parts of India, I am, says Mr. Simmonds, indebted to Mr. G. W. Johnson, one of the correspondents of my "Colonial Magazine." Mr. Johnson, besides his own Indian experience, has consulted all the best authorities, and the opinions of contributors to the leading periodicals of Calcutta on this imortant subject:—When America became known to Europeans, its indigo became to them a principal object of cultivation, and against their skill the native Hindostanee had nothing to oppose, but the cheapness of his simple process of manufacture. The profit and extent of the trade soon induced Europeans to brave the perils of distance and climate to cultivate the plant in Hindostan; but those obstacles, added to the superior article manufactured by the French and Spaniards in the West Indies, would long have held its produce in India in subordination, if the anarchy and wars incident to the French Revolution, especially when they reached St. Domingo, had not almost annihilated the trade from the West, and consequently proportionally fostered that in the East. The indigo produce of St. Domingo was nearly as large as that of all the other West India islands together. From the time that the negroes revolted in that islands, the cultivation of indigo has increased in Hindostan, until it has become one of its principal exports and the quality of the article manufactured is not inferior to that of any other part of the world. The most general mode of obtaining the necessary supply of *weed*, as it is called by the planter, is as follows:—The land attached to the factory is parcelled out among the ryots or farmers, who contract to devote a certain portion of their farm to the cultivation of indigo, and to deliver it, for a fixed price per bundle, at the factory; a sum of money, usually equal to half the probable produce, has to be advanced to the ryot by the planter, to enable him to accomplished the cultivation and to subsist upon until the crop is ready for cutting. If, as is generally the case, sufficient land is not attached to the factory to supply it with plant, the owner obtains what he requires by inducing the ryots in his vicinity to cultivate it upon a part of their land. Yet it is with them far from a favorite object of cultivation; and, indeed, if it were not for the money advanced to each ryot by the planter, to provide seed, &c., and which gives him a little ready money, bearing no interest, it is doubtful whether he would engage in the cultivation at all. Even this advance of money does not induce him to appropriate it to any but the worst part of his farm, nor to bestow upon it more than the smallest possible amount of labor. The reasons for this neglect are valid, for the grain crops are more profitable to the ryot, and indigo is one of the most precarious of India's vegetable products. In Bengal the usual terms of contract between the manufacturer and the ryot are, that the latter receiving at the time a certain advance of money, perhaps one rupee (2s.) per biggah, with promise of a similar sum at a more advanced period of the season, undertakes to have a certain quantity of land suitably and seasonably prepared for sowing, to attend and receive seed whenever occasion requires, and to deliver the crop, when called upon, at the factory, at a specified price per bundle or 100 bundles. The particular conditions of these contracts vary generally in Bengal; they amount to advancing the ryot two rupees for every biggah of land, furnishing him with seed at about one-third its cost, on an engagement from him to return whatever his lands may produce (which, as has been said, is generally none at all), at the price charged, and receiving the plant from him at six, seven, eight, or sometimes nine bundles for a rupee—much oftener the former than the latter rates. A ryot cultivating alluvial lands, and having no seed, can hardly ever repay his advances; but it does not follow that he has been a loser, for he, perhaps, could not value

his time, labor, and rent altogether at half the amount; and as long as this system is kept within moderate bounds, it answers much better than private cultivation to the manufacturer, and has many contingent advantages to the cultivator. In Tirhoot similar engagements are entered into with the ryots, who are then called *Assamees*. These engagements with Assamees are generally made in the month of September, on a written instrument called a *novishaun*, by which they agree for a certain quantity of land, for five years, to be cultivated with indigo plant, and for which they are to be paid at the rate of six rupees per biggah, for every full field of plant measured by a luggie or measuring-rod. The luggie, it must be observed, varies in size throughout the district. In the southern and eastern divisions of Tirhoot and Sarun it is eight-and a-half to ten feet long; and in the northern and western from twelve to fourteen feet. The Assamee receives, on the day of making his *bundobust*, or settlement, three rupees advance on each biggah he contracts for, another rupee per biggah when the crop is fit to weed, and the remaining two rupees at the ensuing settlement of accounts. Exclusive of the price of his mal or plant, the Assamee is entitled to receive two or three rupees per biggah (as may be agreed on) for gurkee, or lands that have failed, as a remuneration for his trouble, and to enable him to pay his rent. The foregoing are the principal stipulations of the novishaun, but the Assamee further engages to give you such land as you may select, prepare it according to instructions from the factory, sow and weed as often as he is required, cut the plant and load the bakeries at his own cost, and in every other respect conform to the orders of the planter or his aumlah (managing man). The Assamee is not charged for seed, the cartage of his plants, or for the cost of drilling. I should mention that a penalty is attached to the non-fulfilment of the Assamee's engagements, commonly called *hurjah*, viz., twelve rupees for every biggah short of his agreement, and this for every year that the novishaun has to run. This is, however, seldom recoverable, for if you sue the Assamee in court and obtain a decree (a most expensive and dilatory process), he can in most instances easily evade it by a fictitious transfer of his property to other hands. The planter generally finds it his interest to get the Zemindar of the village in which he proposes cultivating, to join in the novishaun, as a further security; or he engages with a jytedar, or head ryot, having several others subordinate to him, and for whose conduct he is responsible. But a still better system is lately gaining ground in this district, I mean that of taking villages in ticka, or farm, by far the best and cheapest plan that has ever been resorted to for the cultivation of indigo. When the planter cultivates the ground himself, it is called in Tirhoot *Zeraut* cultivation. In this mode, lands are taken on a puttah or lease for five years, at the average rent of three rupees per biggah. The heavy cost attending this cultivation has occasioned its decrease in most factories in Tirhoot and particularly since the fall in prices. About a third, I believe, was the proportion it formerly bore to the whole cultivation of the district, but of late such factories only have retained it as cannot procure sufficient good land under the Assamewar system; but now that the plan of taking villages in farm is becoming more and more prevalent here, it is very likely that Zeraats will be entirely abandoned. From all the information I have been able to collect, the cost of a biggah of Zeraut (ten feet luggie) may be estimated at sixteen rupees; that of Assamewar is generally twenty-five per cent. less, both exclusive of interest, agents' charges, and private expenses. It can only be the reluctance of the ryot to cultivate indigo that induces a manufacturer to grow it himself, for it has been found an expensive plan, profitable only when the dye is at its highest rate, and even then scarcely furnishing an adequate return. They not only could not cultivate so cheaply as the native laboring husbandman, but ordinarily had to engage extensive tracts of land much of which was not suitable for their purpose, or, perhaps, for any other, and consequently, although the average rate of rent was even low on the whole, it constituted a very heavy charge on the portion from which they obtained their return. In Oude there are three systems of obtaining a supply of the plant, viz., *Kush Kurreed*, *Bighowty*, and *Nij*; but the latter is a mere trifle in proportion to the others, and is, therefore, not worth mentioning. On the *Bighowty* system, which prevails chiefly in the Meerut and Mooradabad districts, the planter advances for a biggah of *Jumowah* (irrigated sowings) nine rupees, and for a biggah of *Assaroo* (rain sowings) five rupees four annas. The next year's plant, or *khoonti*, becomes his on an additional payment of eight annas per biggah. He also supplies the seed at the rate of six seers per biggah, being almost double the quantity made use of in Bengal, but which is necessary to make up for the destruction of the plant the year following by the frost, white ants, hot winds, grass cutters, and, I may add, the village cattle, which are let loose to graze on the khoonte during the latter period, when not a blade of grass or vegetation is to be seen anywhere left. The Bighowty system is a sadly ruinous one, as, independently of the attempts to assimilate Assaroo, at five rupees four annas, with *Jumowah*, at nine rupees per biggah, which is very easily effected if the planter is not very vigilant, he is obliged to maintain an extensive and imposing establishment of servants, not only to enforce the sowings, weeding, and cutting, but also to look after his khoonte, and protect it from being destroyed by bullocks and

grass cutters, or from being ploughed up clandestinely by the Zemindars themselves. The Kush Kurreed system again has its evils, as the planter never gets plant for the full amount of his advances, and hence often leads to his ruin.

Soils.—Indigo delights in a fresh soil; new lands, of similar staple to others before cultivated, always surpass them in the amount and quality of their produce. Hence arises the superior productiveness of the lands annually overflowed by the Ganges, the earthy and saline deposits from which in effect renovate the soil. The further we recede from the influence of the inundation, the less adapted is the soil for the cultivation of indigo. The staple of the soil ought to be silicious, fertile, and deep. Mr. Ballard, writing on the indigo soils of Tirhoot, says that high "soomba," or light soils, are generally preferred, being from their nature and level less exposed to the risk of rain or river inundation; but they are difficult to procure, and, moreover, require particular care in the preparation. Next in estimation is "doruss," a nearly equal mixture of light earth and clay; a soil more retentive of moisture in a dry season than any other. "Muttyaur," or heavy clay soils, are generally avoided, although in certain seasons, with mild showers of rain, they have been known to answer. The safest selection I should conceive to be an equal portion of soomba and doruss. In a country, however, interspersed with jheels and nullahs, it is difficult to form a cultivation without a considerable mixture of low lands, more or less, according to the situation of the Assamee's fields. Great care should be taken, at all events, to guard against oosur lands, or such as abound with saltpetre; these can be most easily detected in the dry months. *Puchkatak*, that is, lands slightly touched with *oosur*, have been known to answer, as partaking more of the nature of *doruss* soil; but the crop is generally thin, although strong and branchy. There is another description of land that should be cautiously avoided. It goes by the name of *jaung*, and is a light soil, with a substratum of sand from six to twelve inches below the surface. The plant generally looks very fine in such fields till it gets a foot high, when the root touching the sand, and having no moisture to sustain it, either dies away altogether, or becomes so stunted and impoverished as to yield little or nothing in the cutting. Of the *daub* or *dearab* (alluvial) land, says Mr. Ballard, there is scarcely any in the district except what falls to the lot of my own factories, being situated on the banks of the Ganges and Great Gunduck. Of *bungur*, a stiff reddish clay soil, there is little in Tirhoot; it pervades the Western provinces, and is best adopted, for Assaroo sowings, which do not succeed in Tirhoot.

Preparation of the soil.—The root of the indigo plant being fusiform, and extending to about a foot

in length, requires the soil to be loosened thoroughly to that depth at least. Experience teaches that the fineness of the tilth to which the soil is reduced previously to the seed being committed to it, is one very influential operation for the obtaining a productive crop. Yet in some districts of Bengal, particularly about Furudpore, the sowing is performed without any previous ploughing. This is where the river, when receded, has left the soil and deposit so deep, that about October, or a little later, the seed being forcibly discharged from the sower's hand, buries itself, and requires no after covering by means of the rake or harrow. In Tirhoot they are indefatigable in this first step of the cultivation. Mr Ballard says, that the preparation of indigo lands should commence in September, as soon as the cessation of the rains will permit; and as we do not rely on rain for our sowings (as is the custom in Bengal and elsewhere, and irrigation is never resorted to, from the heavy expense attending it), our principal aim is to preserve as much moisture in the fields as possible. They should receive, for this purpose, not less than eight ploughings, besides a thorough turning up with the spade, after the fourth ploughing, to clear the field from stubble, grass and weeds. It is absolutely indispensable to get all this done on our light soils, especially before the end of October, and have the land carefully harrowed down, so as to prevent the moisture escaping. Should there be heavy rains between the interval of preparing and sowing, it will be necessary to turn the fields up with either one or two ploughings, and harrow them down as before. If only a slight shower, running the harrow over them will be sufficient to break the crust formed on the surface, and which, if allowed to remain, would quickly exhaust the moisture. This, with the occasional use of the weeding-hook, is all that the lands will require till the time of sowing.—("Transactions of the Agri.-Hort. Society of Calcutta," vol. ii.. p. 22).

Sowing.—The time when the seed is committed to the soil varies in different parts of India, and, even in the same place, admits of being performed at two different seasons. The periods of sowing in Bengal are first immediately after the rains, from about the latter end of October. The rivers are then rapidly retiring within their beds, and as soon as the soft deposit of the year has drained itself into a consistency, though not solid enough to keep a man from sinking up to his knees in it, they begin to scatter the seed broadcast. This is continued until the ground has become too hard for the seed to bury itself; the plough is then used to loosen the crust, and the sowing continued to about the middle, or even the end of November, from which period the weather is considered too cold, until February. These autumnal sowings are called October sowings, from the month in which they generally commence. Much of the plant perishes

during the months of December and January, and more again in the spring, unless there are early and moderate showers. The crop that remains is not so productive ordinarily in the vat, as that obtained from spring sowings, and some think the quality of the produce inferior. But there is no expense of cultivation, and the liabilities of the crop to failure are such a discouragement to cost and labor in rearing it, that the October sowing is followed by most planters who can obtain suitable land. The second period of sowing is the spring, with the first rains of March, or even the end of February. The land having been measured and placed under its slight course of tillage during the two or three preceding months, is sown broadcast as soon as the ground has been well moistened, or even in prospect of approaching rain. The quantity of seed used for this autumn sowing is generally more than what is considered requisite for spring sowing; six seers at the former and four at the latter season per biggah, in Bengal, is the quantity usually allowed. Some cultivators commence the autumn sowing as early as at the close of September, or as soon as the low lands are in a state to permit the operation after the inundation has subsided. This seed time may be said to continue until the end of December, and the crops from these sowings often yield an average produce, if the lands are not very low and wet. If they are, the sowing had better be delayed until January, or even February, for the crops from these latter sowings are usually the most productive, and the dye obtained from them the finest. The object for thus delaying the sowing is, that the young plants may have a more genial season for vegetation. Those who prefer sowing earlier, and yet are aware of the importance of saving the young plants as much as possible from the comparative low temperature of the season, sow some other crop with their indigo. Til, the country linseed, is good for this purpose in high lying soils. But I never knew an intermixture of crops that was not attended by inconveniences and injuries more than was compensated by the advantages gained. The success of sowings during March and April is very doubtful. It depends entirely upon the occurrence of rain, which in those months is proverbially uncertain. If the season should be sufficiently wet, the sowing may be performed in May; but a June sowing is very rarely remunerating. The rains setting in during the latter part of this month so promote the growth of weeds, that the young plants are choked and generally destroyed. The exceptions only occur in high lands, in unusually propitious seasons, and ought never to be relied upon, except when the earlier sowings have failed. To protract the manufacturing season, some planters begin sowing upon low lying lands in the hot season, for the chance of a crop at the commencement of the rains; and they sow at the close of the rains with the hope of, as it were, stealing another in the next year. In the western provinces sowing necessarily occurs in the dry weather, usually in March and April, though occasionally either a little earlier or later. In Tirhoot the sowings commence about the latter end of February or the beginning of March, if by that time there is sufficient warmth in the atmosphere to ensure a healthy vegetation. Light soils are sown on one close ploughing; heavy soils on two, with from four to eight seers of seed, in proportion to the size of the biggah. After strewing the seed, the field should be harrowed down by two turns of the harrow, and then again by two turns more after the third day. In case of rain before the plant appears (which it ought to do on the sixth or seventh day), if a slight shower, the harrow should be used again; if very heavy, it were best to turn up the ground and re-sow. If rain fall after the appearance of the plant, and before it has got past four leaves, and attained sufficient strength to resist the hard crust before alluded to, immediate recourse must be had to drilling. In fact, the closest attention is required to watch the state of the young crop for a month at least after the sowings; if it yield the least, or assume a sickly appearance, drills are the only resource. These, if applied in time, in all March, for instance, or before the middle of April at latest, are generally successful, not only in restoring plants, but recovering such as may have become sickly from want, or excess, of moisture, or any other cause. In dry seasons they have been known to give a crop when broadcast sowings have failed. Each drill, with a good pair of bullocks, should do five biggahs a day. They are regulated to throw from three to four seers per biggah, but the qnantity can be increased or diminished at pleasure. The natives do not employ them in their grain sowings, but commonly adopt a contrivance with their own plough for sowing in furrows, whenever their fields are deficient in moisture. The drill employed in Tirhoot resembles considerably the implement known by that name in England. It is found not only to effect a great saving of seed, ten seers being there sown broadcast on a biggah of 57,600 feet square, and only seven seers by this drill; but also materially to improve the quality and regularity of the growth of the plant. Experience has demonstrated, that the more lateral room the plants have, the more abundant is their produce of leaves, in which the coloring matter chiefly resides. The seed employed should always be as new as possible, for though, if carefully preserved, it vegetates when one year old, and even when nearly two years old has produced a moderate crop, yet this has been under circumstances of an unusually favorable season and soil. The plants from old seed rare-

ly attain a height of more than a foot before they wither and dye. As frauds are very likely to be practised by giving old seed the glossiness and general appearance of new, great circumspection should be shown by the planter, who does not grow his own, in obtaining seed from known parties. Planters in the lower provinces are induced to use up-country seed, because, coming from a colder climate, it vegetates, and the plants ripen rapidly, so as to be harvested more certainly before the annual inundation, but they employ one-fourth more. Three seers per Bengal biggah are sufficient, if it is "Dessee" seed; but four is not too much if it is up-country seed. A Bengal biggah is only a third of the size of that of Tirhoot. If the weather is dry, the seed very often does not germinate until the occurrence of rain, and it has been known in a dry, light soil, to remain in the ground without injury for six weeks. If seasonable showers occur, the plants make their appearance in four days, or even less; and they must be watched, in order that they may be weeded on the earliest day that they are sufficiently established to allow the operation to be safely performed. In dry weather, it must not be done while they are very young, otherwise many of the seedlings will have their roots disturbed, and perish from the drought. However, not more than a fortnight should be allowed to pass, after the seedlings have appeared, before the weeds are carefully removed, and this clearing should be frequently repeated until the plants so overshadow the ground that they of themselves keep back the advance of the weeds. The first weeding is best performed immediately after a shower of rain. Irrigation is rarely adopted for the indigo crops in the lower provinces of Bengal, unless they happen to be grown in some situation very favorable to the operation, such as the bank of a river. It is much more attended to in the western province, and in Oude, the water being obtained from wells, which are dug in nearly every cultivated plot. In Oude, Mr. Ballard says that a biggah of land employs three persons to irrigate it, and occupies never less than six days. The ryot, or cultivator, requires for the work a pair of bullocks, which cost him at least 32s., a bucket made of a white bullock hide, at 2s., and a rope for 2s. more, both of which do not last him above a year. He never pays less than 8s. for the rent of a biggah of land near a well. In Bengal the plant requires three months to attain its highest state of perfection for manufacturing, but is often cut, from necessity, within half that time; for the approach of the river compels the premature removal of the crop, unless, indeed, its growth has been so retarded that it would not pay the expense of working. Most indigo factories have consequently to begin in June, or early in July, whenever they may have effected their spring sowings, and the labours of the season are commonly terminated by the middle or end of August. When the plants begin to flower is considered the best time for cutting them, and this is just what the botanist would have suggested, because then the proper sap of all plants is most abundant, and most rich in their several peculiar secretions. A vividly green, abundant and healthy foliage, downy at the back, is the surest intimation of the plants being rich in indigo. Plants that are ready for cutting in July and August, are usually the most productive. In the western provinces from sixteen to twenty maunds of plant is considered a good produce per biggah. In the upper provinces the produce of the best crop, which is sown directly the rains commence, is not more then ten maunds per biggah. The factory maund is equal to about seventy-eight pounds. One thousand maunds of plant are considered as producing quite an average quantity of indigo, if this amounts to four maunds. Adopting another mode of estimate, Mr. Ballard says, that in Bengal an average crop may be considered to be from ten to twelve bundles, over an extensive cultivation, in a good season, from each Bengal biggah; the sheaf or bundle being measured by a six-feet cord or chain. Speaking of the produce in Tirhoot, the same gentleman says the "luggie," or measuring rod, varies throughout the district. The common Tirhoot biggah, is, I believe, equal to two-and-a-half or three Bengal biggahs (about an English acre). Its produce varies according to the size of the luggie, the fertility of the soil, and accidents of season; eight to ten hackery loads, however, is generally considered a good average return. South and east of Tirhoot, one hundred maunds from six hundred biggahs, including "khoonti," or a second cutting, is reckoned a successful result. In another part of the district, including Sarum, where the "luggie" is larger, the average produce is about one-third better. As we measure our plant on the ground (he adds), the bundle system is unknown here; but, I believe, forty-five or fifty Tirhoot hackery loads of plants (estimated to yield a maund of dry indigo), will be found equal to two hundred Bengal bundles.—("Trans. Agri. Hort. Soc., vol. ii. page 23.") In Oude the *jamowah*, or crop sown in May, yields on an average twenty maunds, or say thirteen bundles, per biggah (160 feet square). The "assaroo," or rain sowings, producing a very inferior plant, the average return is not more than three maunds, or two bundles. The "khoonti," or crop of the next year from the same plants, averages fifteen maunds, or ten bundles per biggah. In Central and Western India, the plants are allowed to produce the second and even the third year, according to some statements; but in Bengal the same stocks are rarely suffered to yield a second crop; being nearly all on lands that are under water in

the height of the inundation, the stock is rotted in the ground. Mr. Ballard, speaking of the duration of the plant, says that, as for three years' plant and "khoonti," it is a mere chimera, like the many others with which the planters have hitherto deluded themselves, and which it only requires a little reflection to overthrow. A biggah may be cut here and there, on an extensive cultivation, but it can never be relied upon as forming a part of the cultivation. The uncertainty of the indigo crop has been already noticed, and is, indeed, as proverbial as that from the hop plant in England. In Bengal the crop is particularly subject to be destroyed by the annual inundation of the river, if it occurs earlier than usual. A storm of wind, accompanied by rain and hail, as completely ruins the crop as if devoured by the locust; neither from this latter scourge is the crop exempt. This proneness to injury extends throughout its growth. The seedlings are liable to be destroyed by an insect closely resembling the turnip-fly, as well as by the frog. Caterpillars feed upon the leaves of older plants, and the white ant destroys them by consuming their roots. To these destructive visitations are to be added the more than ordinary liability of the plant to injury, not merely from atmospheric commotions, but even from apparently less inimical visitations. Thus not only do storms of wind, heavy rains, and hail, destroy the indigo planter's prospects, but even sunshine, if it pours out fervently after showers of rain, is apt, as it is properly termed, to *scorch* the plants; and if it occurs during the first month of their growth, is most injurious to their future advance. The reason of this effect appears to be the violent change from a state of imbibing to a rapid transpiration of moisture. No human invention or foresight can preserve the crop from the atmospheric visitations. To destroy and drive away the little coleopterous insects which attack the seedlings, it would be a successful method to spread dry grass, &c., over the surface intended to be cultivated, and to burn the litter immediately before the sowing. The heat and smoke produced has been found perfectly efficacious against the turnip-fly in England. To destroy the caterpillar, slacked lime dusted over the leaves, while the dew is upon them, is an effectual application. The white ants may be driven away or destroyed by frequent hoeings, which is the best preventive of the scorching, for hoeing preserves the soil in an equable and fitting state of moisture. The great supply of seed for Bengal cultivation is obtained from the western provinces, and forms an article of trade of no inconsiderable magnitude. The stubble in the low lands of Bengal is generally submerged before it has time to throw out fresh shoots, on which the blossom and subsequent seed-pod are formed. There are, however, some high tracts reserved for that purpose, and on these the plant is found well in flower in September, and the seed fit to gather in November or early in December. Two methods are pursued to extract the indigo from plant; the first effects it by fermentation of the fresh leaves and stems; the second, by maceration of the dried leaves; the latter process being most advantageous. They are thus described by Dr. Ure, in his "Dictionary of Arts and Manufactures:"—

From the recent leaves.—In the indigo factories of Bengal, there are two large stone-built cisterns, the bottom of the first being nearly upon a level with the top of the second, in order to allow the liquid contents to be run out of the one into the other. The uppermost is called the fermenting vat, or the steeper; its area is twenty feet square, and its depth three feet; the lowermost, called the beater or beating vat, is as broad as the other, but one-third longer. The cuttings of the plant, as they come from the field, are stratified in the steeper, till this be filled within five or six inches of its brim. In order that the plant, during its fermentation, may not swell and rise out of the vat, beams of wood and twigs of bamboo are braced tight over the surface of the plants, after which water is pumped upon them till it stands within three or four inches of the edge of the vessel. An active fermentation speedily commences, which is completed within fourteen or fifteen hours; a little longer or shorter, according to the temparature of the air, the prevailing winds, the quality of the water, and the ripeness of the plants. Nine or ten hours after the immersion of the plant, the condition of the vat must be examined; frothy bubbles appear, which rise like little pyramids, are at first of a white colour, but soon become grey, blue, and then deep purple red. The fermentation is at this time violent, the fluid is in constant commotion, apparently boiling, innumerable bubbles mount to the surface, and a copper coloured dense scum covers the whole. As long as the liquor is agitated, the fermentation must not be disturbed, but when it becomes more tranquil the liquor is to be drawn off into the lower cistern. It is of the utmost consequence not to push the fermentation too far, because the quality of the whole indigo is deteriorated; but rather to cut it short, in which case there is, indeed, a loss of weight, but the article is better. The liquor possesses now a glistening yellow color, which, when the indigo precipitates, changes to green. The average temperature of the liquor is commonly 85 deg. Fahr.; its specific gravity at the surface is 1·0015; and at the bottom 1·003. As soon as the liquor has been run into the lower cistern, ten men are set to work to beat it with oars, or shovels four feet long, called *busquets*. Paddle wheels have also been employed for the same purpose. Menwhile two other laborers clear away the compressing beams and bamboos from

the surface of the upper vat, remove the exhausted plant, set it to dry for fuel, clean out the vessel, and stratify fresh plants in it. The fermented plant appears still green, but it has lost three-fourths of its bulk in the process, or from twelve to fourteen per cent. of its weight, chiefly water and extractive matter. The liquor in the lower vat must be strongly beaten for an hour and a half, when the indigo begins, to agglomerate in flocks, and to precipitate. This is the moment for judging whether there has been any error committed in the fermentation, which must be corrected by the operation of beating. If the fermentation has been defective, much froth rises in the beating, which must be allayed with a little oil, and then a reddish tinge appears. If large round granulations are formed, the beating is continued, in order to see if they will grow smaller. If they become as small as fine sand, and if the water clears up, the indigo is allowed quietly to subside. Should the vat have been over-fermented, a thick fat-looking crust covers the liquor, which does not disappear by the introduction of a flask of oil. In such a case the beating must be moderated. Whenever the granulations become round, and begin to subside, and the liquor clears up, the beating must be discontinued. The froth or scum diffuses itself spontaneously into separate minute particles, that move above the surface of the liquor, which are marks of an excessive fermentation. On the other hand, a rightly fermented vat is easy to work; the froth, though abundant, vanishes whenever the granulations make their appearance. The color of the liquor, when drawn out of the steeper into the beater, is bright green; but as soon as the agglomerations of the indigo commence, it assumes the color of Madeira wine; and speedily afterwards, in the course of beating, a small round grain is formed, which, on separating, makes the water transparent, and falls down, when all the turbidity and froth vanish. The object of the beating is threefold; first, it tends to disengage a great quantity of carbonic acid present in the liquor; secondly, to give the newly-developed indigo its requisite dose of oxygen by the most extensive exposure of its particles to the atmosphere; thirdly, to agglomerate the indigo in distinct flocks or granulations. In order to hasten the precipitation, lime water is occasionally added to the fermented liquor in the progress of beating, but it is not indispensable, and has been supposed capable of deteriorating the indigo. In the front of the beater a beam is fixed upright, in which three or more holes are pierced, a few inches in diameter. These are closed with plugs during the beating, but two or three hours after it, as the indigo subsides, the upper plugs is withdrawn to run off the supernatant liquor, and then the lower plugs in succession. The state of this liquor being examined, affords an indication of the success of both the processes. When the whole liquor is run off, a laborer enters the vat, sweeps all the precipitate into one corner, and enters the thinner part into a spout which leads into a cistern, alongside of a boiler, twenty feet long, three feet wide, and three feet deep. When all this liquor is once collected, it is pumped through a bag, for retaining the impurities, into the boiler, and heated to ebullition. The froth soon subsides, and shows an oily looking film on the liquor. The indigo is by this process not only freed from the yellow extractive matter, but is enriched in the intensity of its color, and increased in weight. From the boiler the mixture is run, after two or three hours, into a general receiver called the *dripping vat*, or table, which, for a factory of twelve pairs of preparation vats, is twenty feet long, ten feet wide, and three feet deep, having a false bottom two feet under the top edge. This cistern stands in a basin of masonry (made water-tight with Chunam, hydralic cement), the bottom of which slopes to one end, in order to facilitate the drainage. A thick wooden web is stretched along the bottom of the inner vessel, to act as a filter. As long as the liquor passes through turbid, it is pumped back into the receiver; whenever it runs clear, the receiver is covered with another piece of cloth to exclude the dust, and allowed to drain at its leisure. Next morning the drained magma is put into a strong bag, and squeezed in a press. The indigo is then carefully taken out of the bag, and cut with a brass wire into bits, about three inches cube, which are dried in an airy house, upon shelves of wicker work. During the drying a whitish efflorescence comes upon the pieces, which must be carefully removed with a brush. In some places, particularly on the coast of Coromandel, the dried indigo lumps are allowed to effloresce in a cask for some time, and when they become hard they are wiped and packed for exportation.

Indigo from dried leaves.—The ripe plant being cropped, is to be dried in sunshine from nine o'clock in the morning till four in the afternoon, during two days, and threshed to separate the stems from the leaves, which are then stored up in magazines till a sufficient quantity be collected for manufacturing operations. The newly dried leaves must be free from spots, and friable between the fingers. When kept dry, the leaves undergo, in the course of four weeks, a material change, their beautiful green tint turning into a pale blue-grey, previous to which the leaves afford no indigo by maceration in water, but subsequently a large quantity. Afterwards the product becomes less considerable. The following process is pursued to extract indigo from the dried leaves:—They are infused in the steeping vat with six times their bulk of water, and allowed to macerate for two hours, with continual stirring, till all the floating leaves sink.

The fine green liquor is then drawn off into the beater vat, for if it stood longer in the steeper, some of the indigo would settle among the leaves and be lost. Hot water, as employed by some manufacturers, is not necessary. The process with dry leaves possesses this advantage, that a provision of the plant may be made at the most suitable times, independently of the vicissitudes of the weather, and the indigo may be uniformly made; and, moreover, that the fermentation of the fresh leaves, often capricious in its course, is superseded by a much shorter period of simple maceration.

PRODUCTION OF INDIGO IN INDIA.

	maunds.		maunds.
1840	120,000	1845	127,862
1841	162,318	1846	101,328
1842	79,000	1847	110,000
1843	143,207	1848	126,565
1844	127,862	1849	126,000

Average of the ten years 126,744 maunds.

The yield from the different districts in 1849, was nearly as follows:—

	maunds.
Bengal,.....	84,500
Trihoot,.....	24,500
Benares,.....	9,500
Oude,.....	6,500
	125,000

In the Madras Presidency, Indigo is chiefly manufactured in the districts of Cuddapah, Nellore, Chittoor, Cuddalore, and Chingleput, but the produce of Cuddapah, in England known as Curpah or Kurpah, is always reckoned of superior quality and brings a higher price than that of other Madras districts. It sells in Madras at from 30 to 45 Rupees a maund of 25 lb. and is chiefly exported to the United Kingdom and France. In former years the usual mode of extracting Indigo, in Southern India, was from the dry leaf, by a process minutely described in the pages of Heyne and Roxburgh. But this is now almost entirely superseded, by the better system of the *green leaf* manufacture, which is followed in all the Indigo growing districts of this Presidency, save the Province of South Arcot. In the latter, the *dry leaf* process is still persevered in, but it is likely that it is only so, from the distance to which the leaf has generally to be carried before it reaches the factory, and the consequent partial drying that takes place on the journey. The Indigo trade of Madras has of late years sustained a great development, though, owing to the drought of 1854, the export fell off above 50 per cent, it having in that year only reached 2,162 Candies (about 4,300 chests) while in 1853, it amounted to 5,445 Candies (about 10,900 chests). The subjoined table of the quantity landed each year in the port of London will show the progress of the trade since 1840.

The average import from Bengal during the same period was about 22,000 chests, so that Madras now contributes 30 per cent. of the whole supply of this dye from India to the London market. But notwithstanding this importance of the traffic, the general manufacture is conducted, in so imperfect a system, that the value of the article produced is seriously diminished, and its currency injured as an article of trade. It is not that the quality of Madras Indigo is inferior to the ordinary run of that of Bengal, for where the manufacture has been conducted on a large scale, and with elaborate care and skill, as in the factories of Messrs. Arbuthnot and Co., at Cuddapah and Bimlipatam and Messrs. Hart and Simpson in the Cuddapah and Nellore districts, an article is produced which is held in high estimation in the home market, and commands as current a sale as the produce of any Bengal factory. But Indigo is commonly manufactured over the Madras Presidency in driblets; one vat-owner often not producing enough to fill even a chest, and the consequence is, that no one can make a purchase of a quantity of Indigo in the Madras market upon a sample, as is commonly done in Bengal,—that every parcel, and often the same chest is of mixed qualities, and that the value of the dye becomes thereby disproportionately depreciated at home. At the Madras Exhibition of 1855, nine samples of *Green leaf* Indigo and four of *Dry leaf* were sent to the Exhibition. The First Prize for the former was awarded to the produce of Messrs. Hart and Simpson's Factory, a beautiful specimen of the dye. Ranking closely with it, was the produce of Messrs. Arbuthnot and Co.'s Factory, which, though not quite coming up to the former specimen in colour, was so well manufactured, so even, square and uniform in quality, as to deserve the highest commendation.

Pala Indigo.—Of the Indigo manufactured from the Pala tree, Wrightia tinctoria, three samples were sent from Madura, Salem, and Canara, but only one deserved mention, that from Messrs.

Fischer and Co. of Salem, which is well manufactured. Fair specimen of the variety, broken square, light, even ordinary copper, sandy. The other samples were heavy, sooty, coarse and grey, as were all the specimens of Indigo sent from the Western Coast.—*M. E. J. R.*

In 1790 the general object of cultivation in Mauritius was indigo, of which from four to five crops a year were procured. One person sent to Europe 30,000 lbs., in 1789, of very superior quality.

Ceylon.—Indigo, though indigenous in Ceylon, is still imported from the adjoining continent, but its growth in this island would be subject to none of the vicissitudes of climate, that in the course of a single night have devastated the most extensive plantations in Bengal, and annihilated the hopes and calculations of the planter at a time when they had attained all the luxuriance of approaching maturity. The district of Tangalle, in the southern province, is the best adapted to the culture and manufacture of indigo for various reasons, such as the abundance of the indigenous varieties of the plant, the similarity of the climate to that of the coast of Coromandel, where the best indigo is produced; facility of transport by water to either of the ports of export, Galle or Colombo, during the south-east, or to Trincomalee by the south-west monsoon; every necessary material is at hand for building a first rate indigo factory, including drying yards, leaf godowns (stores), steeping vats and presses, except roof and floor tiles—which may be obtained in any quantity from Colombo, during the south-west monsoon, at a moderate rate compared with their cost at home. In 1817 an offer was made to the Government to introduce the cultivation of indigo, on condition of a free grant of the land required for the purpose and freedom from taxation for thirty years, after which the usual tax was to be levied; and in case the cultivation were abandoned, the land was to revert to the Crown. But whether from the disturbed state of the colony at the time or from incredulity on the part of the Government, as to the capability of the colony in this respect the application was unheeded. A subsequent proposal, emanating from a Swedish gentleman of great ability, skill and enterprise, was defeated by his death, although a company was on the point of formation to carry out the scheme. It would not be difficult, says Mr. Barrett, to select 500,000 acres, the property of the Crown, which at a comparatively small expenditure might be brought into a proper state of cultivation for the reception of indigo seed; for very little would be required to be done beyond clearing the land of weeds, burning the grass, and then lightly ploughing and levelling the ground; and whenever manure might be requisite, the fecula of the leaf affords one of the richest that could be employed. Ceylon produces two other plants from which a very valuable blue dye may be obtained by a similar process to that of making indigo. The Singhalese head men of the Tangalle district have long been anxious for the establishment of an indigo plantation there, and would readily have taken shares in a company established for that purpose. Indigo would seem to have been exported by the Dutch from Ceylon so late as 1794. The wild varieties of indigo which grow on the sea-shore are used by the dobies (*Washermen*). Indigo grows in a wild state in Siam, and all the dye used in the country is manufactured from these plants. The extensive low grounds are admirably suited for the cultivation of this plant. A large quantity is raised in Manila, but I have no full details of the cultivation in the Philippines. However, in the first six months of 1843, 1,039 piculs of indigo were shipped to Europe, and about 650 to other quarters—equal in all to about 226,000 lbs. in the half year. In the year 1847 the exports of indigo were 30,631 arrobas, equal to about 7,658 cwt.; in 1850 the total exports from Manila were 4,225 quintals.

Java.—The cultivation of indigo was introduced into Java in the time of the company. It was so much neglected during the adminstration of Governor Daendels that the exportation ceased. It however revived subsequently, and in 1823 the exports were close upon 17,000 lbs. In 1826 it had risen to 46,000 lbs. In the single province of Westbaglen, about 60 square miles in extent, 86 indigo factories were established in the course of seven or eight years. In 1839, the exports of this dye-stuff from Java were 588,764 kilogrammes, valued at 7½ million francs. It has been found by experience that a good soil is essentially necessary for the plant, and the indigo transplanted from elevated grounds to the rice fields succeeds better and yields more coloring matter than when raised direct on the spot from the seed. The residencies of Cheribon, Baglen and Madion, are those in which the crop succeeds best. From being so exhausting a crop, and finding it prejudicial to their rice grounds, they are gradually abandoning indigo culture in Java, and about two-thirds of the indigo plantations have within the last year or two been replaced with sugar. The value of the Java indigo is set down at 250 rupees (£25) per maund. If this be the average price, and it cannot be manufactured lower, Bengal has little to fear from Javanese competition. The product of indigo rose from 276 maunds in 1825 to 28,000 in 1842, and the quantity sold by the Dutch Trading Company in the last-named year was 10,500 chests, of about the same dimensions as those usually exported from Calcutta. Some further statistics of the culture in Java are shown in the following returns of the quantity exported:—

	lbs.
1830	22,063
1835	535 753
1839	595,818
1841	913,693
1843	1,890,429
1851	769,580
1852	838,288

The produce in 1848 was 1,151,368 lbs.

	1840.	1841.
Residence in which this culture is introduced	9	10
Number of factories	728	728
Families occupied with this culture	197,085	192,159
Extent of fields where the cutting has been made in *bahus* of 71 decamatres	40.844	38,829
Quantity of *bahus* planted before the gathering	317	538
Quantity of indigo crop in pounds	2,032,097	1,663,427
„ average pounds per *bahu*	49¼	43

The extent of fields destined for the crop of 1842 was 37,970 bahus, and the amount of the crop was calculated by approximation at 1,862,000. The gradual increase of the export in the eighteen years ending 1842, is shown as follows :—

	Maunds.		Maunds.
1825	76	1834	3.310

1842	8,931,112	155,003
1843	6,319,294	130,836

Entered for home consumption about two millions and a half pounds annually. (" Par. Returns No. 656, September 1843, and 426, September 1844.")

The consumption of indigo in Europe and North America in round numbers, estimated from authentic sources, is thus set down by Mr. Macculloch in 1849 :—

	chests.
In Great Britain for home consumption	9,820
„ France total for ditto	10,400
„ American ports from London and Liverpool	2,500
„ „ Calcutta	700
„ „ Holland, &c	400
Other European countries export from London and Liverpool	21,530
„ „ Holland	4,270
„ „ Calcutta	120
„ „ France	300
—*Simmonds, page* 478.	50,040

(4471) INDIGOFERA, a genus of Plants belonging to the natural family *Leguminosæ*, indigenous in the equinoctial parts of Asia, Africa, and America, and celebrated for some of the species yielding Indigo. The species are about 150 in number ; all are small herbaceous or shrubby Plants. The leaves are usually pinnate ; the flowers small and papilionaceous, in axillary clusters of a purple, blue, or white colour. The calyx is 5-cleft ; segments acute ; vexillum roundish, emarginate ; keel furnished with a subulate spur on both sides, stamens diadelphous [9 and 1]. Legume continuous, one or more seeded. Seeds usually truncated, separated by cellular spurious partitions. There is some difficulty in ascertaining all the cultivated species, as the subject is usually neglected both by naturalists and cultivators.—*Eng. Cyc. Vol.* III. *p.* 227. Dr. Wight, in Icones, gives, Indigofera arborea, 368 ; argentea, 331 ; aspalathoides, 332 ; atropurpurea, 369 ; cœrulea, 366 ; *cinerea*, 386 ; echinata, 316 ; enneaphylla, 403 ; flaccida, 387 ; *fragrans*, 385 : glandulosa, 330 ; linifolia, 313 ; paucifolia, 331 ; pedicellata, 983 ; pentaphylla, 385 ; *prostrata*, 314 ; pulchella, 367 ; tinctoria, 365 ; trifoliata, 314 ; trita, 315, 386 ; uniflora, 333 ; viscosa, 404.

(4472) INDIGOFERA. Wild indigo. An indigenous shrub, a species of indigo, is sometimes, in Tenasserim, used in forming a blue dye. —*Mason.*

(4473) INDIGOFERÆ, Sp.

Doun-daloun, Burm.

This tree is four or five feet in girth, found both in the Rangoon and Tounghoo districts, though it is scarce. Wood, white colored, adapted to every purpose of house-building.—*McClelland.*

(4474) INDIGOFERA ANIL. From the name it might be inferred that this was an Asiatic plant ; but it is said by De Candolle to grow wild in America, and to be cultivated in both Indies, as also along the Gambia in Africa. The name Anil, which has passed into the Spanish, has evidently the same origin as the Arabic Neel, or Nil. The Spaniards and Portuguese,

who had found the way to India by two opposite courses, must there have become acquainted with Indigo, and adopted its Indian name: they were the first to manufacture it in America—the Portuguese in Brazil, and the Spaniards in Mexico. This species is characterised by an erect suffruticose stem; leaves pinnate in 3 to 8 pairs; leaflets oval-oblong, scarcely pubescent on the under surface; racemes axillary, shorter than the leaves; legumes compressed, not torulose, deflexed, curved, with both sutures thickened and prominent, 10- to 12-seeded. Messrs. Wight and Arnott state, "We have not sufficient materials to enable us to determine if *I. Anil* be a distinct species. We know of no distinguishing character, unless it is to be found in the fruit, and the descriptions given of that part in the two species differ in different authors." But the authors of the 'Flore de Senegambie' consider them distinct, as do most botanists. According to Dr. Honigberger, p. 289, Indigofera Anil, is cultivated in some provinces of the Punjab, but more for dye, than for medicine. The leaf of the *Indigofera Anil* (Vishaso Danie, *Sans.*) is used by the natives in hepatitis. Powdered indigo has been employed in Germany in the treatment of epilepsy, but with very uncertain results.—*O'Shaughnessy, p.* 292.

(4475) INDIGOFERA ARGENTEA, is a species usually stated to be a native of India, and the authority of Dr. Roxburgh might be cited for the fact; but Messrs. Wight and Arnott state that *I. aryentea* of Linnæus is not found in India. It is the species cultivated in Egypt and Barbary for the sake of its Indigo, and, according to Humboldt, also in America. The Indian species which has been confounded with it is *I. paucifolia* of Delille, which has alternate leaflets, and linear, slightly compressed, torulose legumes. *I. argentea* is shrubby, with round branches, which appear of a silky whiteness from appressed pubescence; leaves pinnate, 1- to 2-paired; leaflets opposite, obovate, silky-pubescent; racemes shorter than the leaf; legumes pendulous, much compressed, torulose, canescent; 2- to 4-seeded.

(4476) INDIGOFERA CÆRULEA (Roxb.). This is a new species described by Dr. Roxburgh, and called Karneeli in Telinga by the natives of the peninsula of India. He states that from the leaves of this plant he had often extracted a most beautiful light Indigo, more so than he ever could from the common Indigo Plant, or even from *Nerium tinctorium*, and in a large proportion. He says it is an erect shrubby species, growing in dry barren uncultivated ground to the height of 3 feet, and higher in good garden soil. It flowers during the wet and cold seasons. The leaves are pinnate; leaflets 4-paired, obovate, emarginate; racemes rather shorter than the leaves; legumes reflexed, curved, contracted between the seeds, hairy; from 3- to 4-seeded. De Candolle inquires whether this be sufficiently distinct from *I. tinctoria*. Dr. Roxburgh states that it comes near to *I. argentea*, Linn. The process he adopted for extracting Indigo from this plant was similar to that practised with the leaves of *Nerium tinctorium*, or the scalding process.—*Eng. Cyc.*

(4477) INDIGOFERA DISPERMA. This, according to Humboldt, is also one of the species cultivated in America, and seen among the most ancient hieroglyphical paintings of the Mexicans. Dr. Bancroft considers it as the species called Guatemala Indigo, which yields fine pulp, but is less productive than other species. The stem is herbaceous, weak; the branches round; leaves pinnate, 4- to 6-paired; leaflets elliptico oblong, smooth; racemes slender, larger than the leaf; legumes round, subtorulose, mucronate; 2-seeded.—*Eng. Cyc.*

(4478) INDIGOFERA ENNEAPHYLLA. The expressed juice of the "trailing indigo," *Indigofera enneaphylla*, is given as an alterative by the native physicians in old syphilitic diseases.—*O'Shaughnessy, page* 292.

(4479) INDIGOFERA LINIFOLIA, vegetates in the lower mountains of the Punjab. There the root of this plant is said to be officinal and to be used in febrile eruptions. It is Dealsings root for Torkee.—*Honig.*

(4480) INDIGOFERA TINCTORIA.

Tarum, MALAY.	Tayum, TAGALA.
Talum, LAMPUNG.	Tayung, BISAYA.
Tom, JAVANESE.	

Indigofera tinctoria.—Is the species generally cultivated in India, whence it has been introduced both into Africa and America. It is suffruticose, erect, branched; leaves pinnate; leaflets 5 or 6 pairs; long obovate, scarcely pubescent, racemes of flowers axillary, shorter than the leaves. Legumes approximated towards the base of the rachis, nearly cylindrical, slightly torulose, deflexed, and more or less curved upwards; sutures thickened; seeds about 10, cylindrical, truncated at both ends. This species is sometimes called Indigo Franc, and French Indigo in the West Indies. It is said to be found wild along the sands of Senegal. ('Flore de Senegambie,' vol. i. p. 178.)—*Eng. Cyc.* The true indigo plant, Indigofera tinctoria, is grown occasionally by both Karens and Burmese, but not extensively.—*Mason.* Some of these Indigo plants are very beautiful, natives of India, and worthy of a place in any garden; the colours being purple, red or pink.—*Riddell.*

(4481) INDURJUO, BITTER.

Indurjuo-i-tulkh, PERS.

Seeds of Holarrhena pubescens, "*Roora*," and H. Antidysenterica, the same size and colour, furrowed deeply at one side: very bitter—*Pen. Ph.* 208.

(4482) INDURJUO, MILD.
Indurjuo-i-shereen, PERS.

Seeds of Wrightia anti-dysenterica, about ¾ inch long, brown, nearly tasteless.—*Ben. Ph.* 208.

(4483) INGA, a genus of Plants belonging to the natural order *Leguminosæ*, which, though it has been separated from *Mimosa*, yet contains upwards of 100 species. These are found in the tropical parts of Asia, Africa, and America. They are distinguished by their legumes being broadly linear, compressed, and 1-celled. The seeds are usually covered with pulp, more rarely with farinaceous matter or a pellicle. The species form shrubs or trees, and are commonly unarmed. The flowers are in spikes, or are capitate, and of red or white colour. From the number of species in this genus, as well as in *Acacia* and *Mimosa*, and from their having been removed from one to the other, there is some confusion in the synonyms. A few of the useful species have been further separated into the genus *Parkia*; but many still remain which are important in the countries where they are indigenous, either for astringent properties, like many Mimosas and Acacias, or for the edible nature of the fecula or pulp which surrounds their seeds. Thus *I. cochliocarpus* has bitter and astringent bark, which is used in tanning and also in medicine. It is taken to Portugal, where it is called the Brazilian Bark, and used even as a substitute for that of the *Cinchona*. Martius distinguishes from this species, which he calls *I. Jurema*, another which he has named *I. astringens*, and of which the bark has similar properties. The bark of these trees is considered by some authors to be the Cortex Astringens Brasiliensis of old pharmacopœias. *I. salutaris* is another astringent species, a native of New Granada, of which the bark is much used in the form of decoction for various complaints in which astringents are indicated, and for the same purposes as Ratany Root. Some of the species, as before mentioned, are esteemed for the sweetish edible pulp with which their seeds are surrounded, as *I. dulcis* in India and *I. insignis* in the province of Quito, where it is called Guabo, or Guabas, but Pacaes in Peru. So *I. Camatchili*, according to Perrotet, is similarly esteemed in Manilla, and *I. Furoba* in Western Africa, in the neighbourhood of the Senegal. *I. vera* contains tannic acid, and is one of the numerous leguminous plants used for obtaining Catechu. The pulp of the fruit of this species also is purgative. *I. fæculifera* yields in its pods a laxative pulp called Pois-Doux in St. Domingo. It has a sweet taste. The pulp also of the pods of *I. tetraphylla* is sweet and mucilaginous. (Lindley, *Vegetable Kingdom.*)

(4484) INGA BIGEMINA.
Tau-yew, BURM.

Native gardens, in Tenasserim, are often ornamented with a species of inga which affords a thick beautiful shade, and when in flower its tufted boughs seem to bend under their burdens of sweet, scented blossoms. It is a leguminous plant, whose seeds are poisonous and when taken into the stomach sometimes produce disastrous consequences, yet the Burmese and Karens are extravagantly fond of them, as a condiment to their preserved fish, and they bring a high price in the bazars.

(4485) INGA DULCIS. Sweet Inga or Manilla Tamarind.
Seema chinta, TEL. | Coorkapooli marum, TAM.

A most valuable hedge plant, is now used along the line of railway, the wood is hard Isolated trees of 12 to 18 inches diameter are occasionally found, these resemble the hawthorn in general appearance. It is the *Pithecolobium dulce*, Benih. The pulp of the fruit is eatable, the seed was brought from Manilla to Samulcottah, hence the name "Manilla tamarind." The Spaniards introduced the tree to the E. Indies from Mexico. —*M. E.* Inga dulcis, says Mr. Jaffrey, is a large and handsome tree, with drooping branches armed with short straight thorns. Pods curiously twisted, filled with a sweet pulp, which forms a nourishing food. This is the best hedge plant in South India.

(4486) INGA XYLOCARPA, MIMOSEÆ, Roxb. c. 100.
Eroovaloo marum, TAM. | Tangedu mara, TEL.
Pyenkadoe, BURM. | Jamboo, HIND.

This tree grows to a large size, and is much valued for house building, on account of its strength and toughness. It is remarkable for its thick woody legume, and is the *Xylia dolabriformis* of Benih.—*M. E. of* 1855. Mr. Mason says that this is a species of the old genus acacia, and its timber is usually denominated iron wood in Arracan, and is sometimes so called in the Tenasserim Provinces. The hard wood is as impervious to white ants as teak, and is even more durable in the ground. Natives have assured him that they have seen house posts of this wood taken up after having stood forty years, and that the part which had been buried was as sound as new timber. The trees abound in the province of Tavoy, especially near the forks of the Tenasserim.—*Mason.* Dr. McClelland however states that both *Inga xylocarpa* Pyin Kadoe. and 2 *T. bijemina*, Tauyeu, afford iron-wood. This first is called Pin-ka-doe by the Burmese. It is found in all the Teak Forests. In the Prome Forests it is usually about six feet in girth, but in all the other Forests it attains a larger size, frequently eight or nine feet. It is most plentiful throughout the province. The second species is of smaller girth, but grows to a great height. Wood black.—*McClelland.* Dr. Wight describes it as a dark coloured, hard and very strong wood, excellent for naves of wheels and in-

deed for all purposes demanding great strength. He believes it is abundant in the Walliar forests. An inch bar sustained 250 lbs.—*Wight.* Mr. Rohde says it is the Conda Tangeda of the Circars. Roxburgh states it to be used for knees and bends of ships in Pegu. In the Circars he has not met with it exceeding a foot or 14 inches diameter and always faulty in the centre, the quantity brought down is comparatively small, he thinks it a good wood for screws, framing of furniture, linings of drawers, tool handles and generally for all purposes for which a moderately hard, strong wood not liable to split or cast about is required; polished it has something the appearance of a close grained palur, and has been sold by hard wood dealers in London as "patridge wood."—*Rohde.*

(4487) INK.

Sira, Tel.	Inchiostro, It.
Mye, Tam.	Atramentum, Lat.
Ink, Dut.	Shai, Pers.
Encre, Fr.	Tschernilo, Rus.
Dinte, Ger.	Tinta, Sp.
Seahi, Guz. Hind. Pers.	Blak, Sw.

Is composed of different ingredients, the chief of which are gall-nuts, copperas, gum, and logwood, according to the purposes to which it is to be applied. There are several varieties of ink, such as printing ink, writing ink, marking ink, India ink. &c. The Ink of China is brought over in small oblong cakes, readily diffusible in water. It is made of very fine lamp black, prepared with a peculiar glue, or jelly. Comp-Desc. The Tamools occasionally make ink with nearly the same materials that we do, but that which is used by the Hindoo Native Writers in the Cutcherries and Public Offices is prepared by the following very different process. *First*, a burnt rice water is to be made in this way; half a seer of rice burnt black is to be well boiled in a seer and a half of water, till but one seer remains then strain off the dregs. To this seer of burnt rice water is to be added two pollams of Komburruck (Lac), boil them well together and strain off the dregs. Half a seer of Carpoo vernum (Lamp black) and half a pollam of Vullam pisin (Gum Arabic) are then to be well rubbed into a fine powder, and gradually added to the decoction of Komburruk and burnt rice water, when the whole are to be rubbed together and well shaken, at different intervals for the space of three days. The Mahometans prepare their ink, which they call Seeahee, in the following manner. Take of Lamp black and Gum Arabic equal quantities and pound them together into a very fine powder. This powder is then to be moistened with the juice of the pulp of the Kuttalay (Small Aloe,) and well rubbed at intervals for two days together after which it is to be formed into little cakes that are to be put on plantain leaves, and dried in the sun for use.—*Ain's. Mat. Med. p.* 175.

(4488) INK, RED.

Segapoo Mye, Tam.

The Tamools prepare this by adding a little water to Shem pungie (red cotton) luttooka doodi, Tel.—*Ain's. Mat. Med. p.* 175. Red ink is formed by steeping and afterwards boiling chips of red dye woods in Vinegar that formed by lake is not permanent.—*Rohde, M.S.S.*

(4489) INSECTA, one of the classes of Invertebrate Animals. The Latin term Insecta, like Greek Entoma, which has been applied to these animals, has reference to the insected or divided appearance of the body; hence the English name Insect, the French Insecte, and the German Insect. Invertebrate Animals are divided by Lamarck into two groups, which he calls Animaux Apathiques, and Animaux Sensibles. The latter, or the Sensitive Animals, contain six classes, of which Insects are the first. According to Latreille's arrangement in the 'Regne Animal,' the class *Insecta* forms the third great division of articulated animals—articulated referring to the innumerable joints of which this class of animals is composed. True Insects may be thus defined:—Articulated animals possessing six legs, two antennæ, two compound eyes; a small brain at the anterior extremity of a double medullary chord. Circulation effected by a Pulsating dorsal vessel provided with numerous valves. Respiration by tracheæ, which form two lateral trunks, and ramify through the body; generation oviparous; two distinct sexes; adult state attained through a series of metamorphoses, Insects generally possess two pairs of wings; the trunk in the adult animal is usually composed of three chief parts, the head (Caput), Thorax, and Abdomen; or the trunk of an insect may be described as consisting of thirteen segments, of which one constitutes the head, three form the Thorax, and the remaining nine compose the Abdomen. The head includes the organs of sensation and manducation, and its principal parts have received the following names:—the Clypeus, Vertex, Occiput, Lenæ, Canthus, Gula, Oculi, Stemmata, Antennæ, and the Trophi.—*Eng. Cyc.*

(4490) INULA, a genus of Plants belonging to the natural order *Compositæ* and the sub-order *Asteraceæ*. It has a many-flowered heterogamous head. Florets of the ray female in one row, sometimes by abortion sterile, usually ligulate sometimes somewhat tubular and trifid; those of the disc hermaphrodite, tubular, 5-toothed; involucre imbricated in several rows; receptacle flat or somewhat convex, naked; anthers with 2 setæ at the base; achenium without a beak, tapering, or in *I. Helenium* 4-cornered; pappus uniform in one row, composed of capillary roughish setæ.—*Eng. Cyc.*

(4491) INULA ROYLEANA, grows in the Cashmerean hills, but as the plant is considered

poisonous it is not used. Dr. Honigberger is of opinion, that important, virtues lie hidden in it, and that it is well worthy of being experimented with.— *Honigberger, p* 290.

(4492) INULA VISCOSA AND GRAVEOLENS, have been lately recommended as diuretics, and as useful in calculous diseases.— *Honigberger, p* 290.

(4493) IODINE.

Iode, Fr. | Iod, Ger.

Iodine (I=126), from *ἰώδης, violet*, the colour of its vapour, was obtained by M. Courtois in 1812 in the residual liquor of the process for obtaining Soda from Kelp. Though but lately discovered, its effects have long been obtained in medicine, as it is found in Sea and several Mineral waters, and in Sea-weeds, Sponge, Corals, and some Molluscous animals. In the present day, the leaf of a Sea-weed (a species of Laminaria, *Dr. Falconer*) is employed in the Himalayas, and called the *goitre-leaf*, and in S. America the stems of a Sea-weed are sold by the name of *goitre-sticks*, because they are chewed by the inhabitants wherever goitre is prevalent.—*Royle.* Iodine is procurable by burning large quantities of sea weed or of the conferva of the salt water lake near Calcutta: but to prepare it from these, the process is only economical where the weeds yield enough of impure Carbonate of soda, to cover the general expense of this operation. This is not the case with the Calcutta conferva.— *Beng. Phar. p.* 870.

(4494) IONIDIUM, a genus of Plants belonging to the natural order *Violaceæ*. It has 5 sepals not prolonged at the base; corolla unequal, 2-lipped, consisting of 5 petals, the lowest of which is very large and unguiculate; stamens 5, hypogynous, unequal, the two anterior having anthers that are often appendiculate; capsule protected by the permanent sepals; petals and stamens few, or many-seeded. The species are herbaceous plants or shrubs.—*Eng. Cyc.*

(4495) IONIDIUM IPECACUANHA, is a native of the forests of Brazil. It has alternate lanceolate ovate leaves, serrated, acute at each end; stipules ovate-lanceolate, acute, membranous, ribbed in the middle; sepals semi-pinnatifid; lower petal very large, transversely elliptical. The roots are emetic, and are often collected as a substitute for the true Ipecacuanha.—*Eng. Cyc.*

(4496) IONIDIUM SUFFRUTICOSUM. *Syn.* Viola suffruticosa, (L.)

Ruttun puruss, Duk. | Charati, Sans.

A rugged and somewhat prickly reclining herb, having a small crimson flower. It is common over the peninsula of India, and is used as a demulcent. Dr. O'Shaughnessy examined carefully specimens obtained from the Calcutta Garden, but did not detect the least trace of the active principles emetine or violine.—*O'Shaughnessy, page* 209.

(4497) IORA, or JORA, a genus of Birds established by Dr. Horsfield, and placed by Mr. Swainson among his *Brachypodinæ*, or Short-Legged Thrushes.

(4498) IPOMÆA, a genus of Plants of the natural family of *Convolvulaceæ*. which is very closely allied to *Convolvulus*, or Bindweed, whence has been derived its name. From the more minute investigations of modern botanists considerable changes have taken place in the nomenclature of the species sometimes referred to this genus and sometimes to other nearly allied genera. M. Choisy, who has most recently examined the Oriental *Convolvulaceæ*, excludes many species usually referred here, and forms the genus of the species of *Ipomæa* and *Convolvulus* of authors. *Ipomæa* has a 5-sepaled calyx, a campanulate corolla, with five stamens included within it; style single; stigma bilobed; lobes capitate; ovary 2-celled; cells 2-seeded; capsule 2-celled. The species are very numerous, and found in the tropical parts of Asia, Africa, and America. A few ascend the mountains in such latitudes. Most of the species are ornamental; others have been removed to *Quamoclit, Argyreia, Pharbitis, &c.*, and one of the most useful as an article of diet in tropical countries, to *Batatasas*. *B. edulis* produces the tubers so well known by the name of Sweet Potatoes. —*Eng. Cyc.* Roxburgh in his Flora Indica page 497 to 504 describes eleven species of Ipomæa. Dr. Wight in Icon. gives Ipomæa, 1356; bracteata, 1374; campanulata, 1374; chrysoides, 157; pes tigridis, 836; pileata, 1363; pulchella, 156; Ipomæa rugosa, 887; sessiliflora, 169; Wightii. 1364; The species and varieties of *Ipomæa* are pretty creepers flowering in the morning. They greatly enhance the beauty of Indian gardens, when the various colors are well arranged, raised from seeds sown at the commencement of the rains, they may be sown where intended to flower. Any garden soil will suit, if not too heavy. —*Riddell.* Mr. Williams says that in China, the large family of Convolvulaceæ contains many beautiful species of Ipomæa, cultivated for their flowers, especially the Ipomæa quamoclit, found about the houses even of the poorest people.— *Williams' Middle Kingdom, page* 287.

(4499) IPOMÆA. Arrow-headed Ipomæa. There is an elegant little twining species of Ipomæa with arrow-headed shaped leaves. The corolla is cream-coloured with a purple eye. It is in bloom in the hedges of Maulmain at the close of the rains.—*Mason.*

(4500) IPOMÆA BONA-NOX. Muricata. (Hairy.) Rubro-Cœrulea (blue and pink.) Tyrianthina. (Bright violet.) Violacea. (Violet Blue.) Splendens, (pale red.) Tuberosa (yellow species.)

(4501) IPOMÆA COCCINEA. A beautiful species herbaceous and shrubby, well adapted for

covering trellis work, walls, or pillars, growing easily from seed, at the commencement of the rains in any good soil, when they produce flowers in profuse abundance.—*Riddell.*

(4502) IPOMÆA CŒRULEA. SKY-BLUE IPOMÆA.

Neel-kulmi, HIND.

Seeds Inflaton and Kala-dana. This grows wild in the hedges about Ajmeer. The seeds called kala-dana are kept by the punsaries and are much employed as a purge; but reckoned very irregular in operation. One tola is taken by an adult as a dose.—*Gen. Med. Top. p.p.* 144 and 181. The seeds of this plant are officinal all over Hindostan and the Punjab, the natives administer them chiefly as purgatives.—*Honigberger, p.* 291.

(4503) IPOMÆA CUSPIDATA, is a creeping weed, and Dr. Honigberger, p. 291, states its leaves are used medicinally.

(4504) IPOMÆA DASYSPERMA, the seeds of this plant Dr. Honigberger received from Hindostan, as an antidote to hydrophobia. It is called Koota ke beenj. i. e. the seeds for dogs, he had not an opportunity of trying them in Hydrophobia.—*Honigberger, p.* 291.

(4505) IPOMÆA JALAPA. JALAP PLANT. *Syn.* Convolvulus Jalapa, *Linn.* Ipomæa Purga. *Wenderoth.* A native of South America, Xalappa, and on the Eastern declivity of the Mexican Andes. The roots are fleshy, large oval oblong, rugose, and blackish externally, while recent; in dry state, and as sold in the shops, they are cut in flakes of variable diameter, sometimes cleft lengthwise and pyriform. If entire they are usually small, wrinkled, heavy, unequal, hard, brittle, deep brown grey externally, of a dirty grey within, fracture smooth and wavy, shewing a great number of resinous points, visible to the lens, and often to the naked eye. The odour is peculiarly nauseous, thoug[illegible] week. The taste acrid and disgusting. A br[illegible] cathartic. The powder is of brown grey colour, and must be prepared with caution, as it is exceedingly irritating. The worm-eaten roots are much more active than the sound, as the worms only attack the amylaceous and sweet parts. The resin of jalap is dry, brittle, readily reduced to powder, in rolls of elongated or spiral form, the size at most of the little finger, greyish yellow, dull, unequal, and chinked externally, of brilliant fracture and yellowish brown while recent. Totally soluble in alcohol, insoluble in ether, inodorous until rubbed, when the peculiar smell of jalap is evolved; its taste is nauseous and very acrid. This resin is exposed to numerous adulterations, especially with other resins, of which that of the Guaiac is most used; the perfect insolubility of the jalap resin in ether will lead to the detection of numerous frauds of this description. According to Humboldt 400,000 lbs. weight of jalap roots are annually exported from Vera Cruz. The plant thrives best on cool shady hills, about 2000 feet above the level of the sea.—*O'Shaughnessy, pages* 502, 503.

(4506) IPOMÆA MACRORHIZA is supposed to be the *Convolvulus Jalapa* of Linnæus. It is a plant inhabiting the sandy soil of Georgia and the Carolinas, with white insipid farinaceous roots, weighing from 40 to 50 lbs. It is said to possess no purgative properties, but, like *Batatas*, consists chiefly of saccharine and farinaceous matter.—*Eng. Cyc.* In 1834, Lord Auckland introduced into the Calcutta Garden, the *Ipomæa macrorrhiza*, a native of Georgia and Carolina. It perfectly succeeded, and the roots attained such an enormous size that a cluster belonging to one plant weighed 70 lbs.; while recent it was fleshy, white, juicy, of mild flavour, and altogether devoid of the acrid resin. It had a sweetish taste, and has been eaten by several persons without any ill effect being experienced. To test the applicability of the root as fodder, seven sheep were fed on it, but six of them died suffering from diarrhœa within a month.—*O'Shaughnessy.*

(4507) IPOMÆA MARITIMA is a plant of extensive range, trailing over the sandy beaches along the coast from Hainan to the Chusan archipelago.—*Williams' Middle Kingdom, p* 287.

(4508) IPOMÆA PESCAPRÆ. GOAT-FOOTED IPOMÆA. On the sands of the sea shore, this large red-purple flowered species of ipomœa is abundant and helps to bind the shifting sands. —*Mason.*

(4509) IPOMÆA PESTIGRIDIS. TIGER'S FOOT IPOMÆA.

Kunra Pora-batul, HIND.

Very common in the rains every where in Rajpootanah. Another and most beautiful extensive perennial Ipomœa is to be seen at Rajgurh and in the resident's garden at Ajmeer generally called the Malabar creeper, it has bright yellow flowers and glabrous palmate leaves. This species seems to agree with the *Ipomœa Tuberosa* of the West Indies, only this has no scent. This plant extends an immense length and affords a very close shade.—*Genl. Med. Top. p.* 182. In Tenasserim the tiger-footed ipomœa, with large palmated leaves is not uncommon.—*Mason.*

(4510) IPOMÆA PHÆNICEA, Scarlet Ipomœa common in hedges and gardens during the rains.—*Genl. Med. Top. p.* 181.

(4511) IPOMÆA PILEATA. BONNET IPOMÆA. In October, as soon as the rains close, a pretty little twining species of Ipomœa is seen blushing through every hedge and bush in Tenasserim. It is peculiar for its concave bonnet shaped involucre, in the midst of which

half a dozen tiny blossoms hide their rosy lips. —*Mason.*

(4512) IPOMÆA QUAMOCLIT: WING LEAVED IPOMÆA, White and crimson. Lal-kamluta. Hind. (The crimson) sweta kamluta (the white). Pers Ishk pecha (love's ringlets)—*Genl. Med. Top. p.* 181. The Cyprus Vine or Crimson Quamoclit. Flowers in the cold weather, of a most beautiful bright crimson colour; tube long, slender; in gardens pretty common.—*Riddell.*

(4513) IPOMÆA RENIFORMIS.

Perretay-keeray, TAM.

A perennial creeper with yellow flowers; the leaves used as greens mixed with tamarind; very common during the cold months.—*Jaffrey.*

(4514) IPOMÆA REPTANS.

Vellay-keeray, TAM.

A creeping annual of the convolvulus family with rose colored flowers, found about the borders of tanks and moist places. The leaves are used as greens.—*Jaffrey.*

(4515) IPOMÆA SEPIARIA.

Thalee-keeray. TAM.

A climbing perennial plant of the convolvulus family with rose colored flowers, found in hedges; the leaves are eaten mixed with others as greens.—*Jaffrey.*

(4516) IPOMÆA TUBEROSA. Malabar Creeper. An immense climbing plant, with woody stem; common in gardens; a native of Tropical America; leaves palmated, seven parted. Flowers yellow and showy appear in October and November. It is in general use for covering old walls, trellises, &c., and for which purpose, from its exceeding rapid growth, it is well adapted.—*Riddell.*

(4517) IPOMÆA TURPETHUM, Syn, CONVOLVULUS TURP.

Teoree, Doodh-kulmee, &c. HIND. and BENG.

A native of Bengal, Ceylon, and India generally.—*Roxb. Fl. Ind.* i. p. 476. *I. Turpethum* is found in the East Indies, Malayan Archipelago, Australia, Timor, Otaheite, Friendly Islands, Marianne Islands, Tinian, &c. Its root is perennial. The stems twining, several fathoms long, from 3- to 4- sided, a little downy, with winged angles; leaves stalked, varying in form from cordate to linear, all pointed and lobed, or angular and downy; peduncles axillary, downy, many-flowered; flowers large and white; bracts oval, concave, velvety, decidous; ovary seated on a large glandular disc; stigma 2-lobed; capsules involved in the dry calyx, absolutely 4-sided, 2-celled, opening at the apex by a kind of operculum; seeds round, black, one in each cell. The root has been long employed in India as a common purgative. The bark of the roots is the part employed by the natives, as it contains all the active properties; they use it fresh, rubbed up with milk. About 6 inches in length of a root as thick as the little finger they reckon a common dose. (Roxb). It is reckoned an excellent substitute for jalap, and is free from the nauseous taste and smell of that drug. The plant is a native of all parts of continental and probably of insular India also, as it is said to be found in the Society and Friendly Isles and the New Hebrides.—*Eng. Cyc.* The recent roots are very long, cylindrical, bent, brached, gorged with acrid milky juice, the dried roots are in broken pieces the thickness of the finger, and 4 or 5 inches long. They are separated from the ligneous part, and consist of a grey or slightly reddish cortical system, composed of parallel longitudinal fibres, and of proper vessels in which particles of resin are observed; inodorous, tasteless at first, subsequently nauseous and acrid. The natives of Bengal use this root as a purgative, rubbing up a slip of the bark with water on a stone and swallowing the emulsion thus formed. A strip six inches in length from a root as thick as the little finger is deemed a sufficient dose. Mr. Gordon, Dr. Glass, and Dr. Wallich, have published several notices of its effects in Carey's edition of Dr. Roxburgh's Fl, Ind. ii. p. 57. Dr. O'Shaughnessy, also subjected its properties to careful clinical experiment, and asserts that the action of the medicine is so extremely uncertain that it does not deserve a place in our Pharmacopæia. —*O'Shaughnessy, page* 504.

(4518) IRIARTEA. A genus of palms peculiar to the forests of South America. I. exorrhiza, Mart. is the *Pashiuba* or *Pasciuba* of Brazil, produces a fruit used as fruit. The Iriartea setigera, Mart is fabricated into blow pipes. The *I. Anticola*, Sp. is the Wax-palm of the Andes. This genus might be introduced into India with advantage.—*Seeman.*

(4519) IRIDACEÆ. This order is remarkable for containing the saffron (*Crocus sativus*) and the *iris*, more than one species of which affords the Orris root of commerce. Their properties are of trivial importance in a medicinal point of view.—*O'Shaughnessy, page* 654.

(4520) IRIS FLORENTINA. FLORENTINE IRIS. A native of Italy and Asia Minor. The roots are the *orris root* of European shops. This article contains volatile acrid resin, astringent matter, gum, extractive, starch, and woody fibre; in full doses it is emetic and purgative. Peas turned from the wood are used in issues to support suppuration. Reduced to powder it is a favorite ingredient in hair and tooth powder. Excellent orris root is procurable in the Calcutta bazars under the name of *Begbanopsha*. Mr. Royle under this head very confidently refers the *putchuk* of commerce to this article. A species of Iris is cultivated in India. Its roots are used in the same manner as those of the Florentine kind.—*O'Shaughnessy, page* 654.

(4521) IRIS XIPHIOIDES. There are the fibrous rooted and tuberous rooted kinds of iris:

species numerous, hybrids, the tuberous rooted are said to be the most difficult to cultivate. though most of the species thrive well in India, they require merely a good rich soil.—*Riddell.*

(4522) IRON.

Heeded, ARAB.	Ferrum. LAT.
Jern, DAN.	Mars, PERS.
Yzer, DUT.	Ahan, POL.
Fer, FR.	Zelazo, PORT.
Eisen, GER.	Ferro RUS.
Loha, GUZ. HIND.	Scheleso, SANS.
Ferro, IT.	*Faulkner.*

Iron is found native, when it is supposed to be generally of meteoric origin ; extensively in combination with Oxygen or Sulphur, as a Salt of various acids, as Carbonate, Sulphate, &c. ; and all these in a more or less pure state, that is, mixed with earths or other metals. It also exists in vegetables, and in the blood of animals. It is extracted from Iron ores. Some of the Oxides, as Magnetic and Specular Iron ore, are heated only with Charcoal, as in Sweden, Elba, and India, when the Carbon combining with the Oxygen, the Iron is set free, and melted. The Carbonate, Iron Pyrites, Clay Iron ore, Red and Brown Hæmatites, and Spathose Iron, are first roasted, and then exposed to a fierce heat in contact with Charcoal, Coke, or small Coal, and a flux, either Lime or Clay, according as the ore is argillaceous or calcareous. These earthy matters become vitrified, and form a slag at the surface, while the heavy particles of Iron, falling down, run out by a hole at the bottom into moulds, and form *Pig* or *Cast Iron*. This is still impure, from the presence of Charcoal, Sulphur, and portions of Silicon and Aluminum. It is again twice fused in the refining and puddling furnaces, and exposed to the influence of a current of air, at a high temperature, when the whole of the Charcoal and Sulphur are burnt out, and the other impurities form a slag at the surface. The metal is taken out, beaten or pressed, and then drawn into bars which form the *Malleable* or *Wrought Iron* of commerce.—*Royle.* Iron Ores, abound in almost every district of India, and the prevailiug ore is the Oxydulous iron, often magnetic, and with polarity ; but specular iron ore, hæmatite, clay iron stone and, sulphuret of Iron, also occur abundantly. In the Malayan Peninsula also, the ores of iron occur in great varieties. The Editor has written largely on these ores, and further information is given in the reports from the geological survey.

(4523) IRON, SULPHATE OF. Sulphate of the Protoxide of Iron.

SYN. Ferrum Vitriolatum.
Sal Martis.
Sulphate de Fer, FR.
Schwefelsaures Eisentxydul, GER.
Eisenvitriol, GER.
Heera kasis, HIND.

Ferri Sulphas.—Green crystals, soluble in water ; does not deposit copper on a piece of polished iron. *Sulphas Ferri.* The Green vitriol. or Heera kasis. The salt is found abundantly by the natural oxidation of the sulphuret of iron, a mineral common especially in coal districts. It occurs in the Indian bazars in large masses of green crystals, and in a state of considerable purity. For Medical use select the greenest and most transparent crystals.—*Beng. Phar. page* 325. Vitriolated Iron, or Green Vitriol, was known to the ancients. It is mentioned in the *Amera Cosha* of the Hindoos (*Hind. Med.* p. 44), and it is used by them, as by the Romans in the time of Pliny, in making Ink. It is found in nature : the Sulphuret, absorbing Oxygen from the atmosphere, is converted into the Sulphate of the Protoxide of Iron ; this is apt to be changed into the red-coloured Sulphate of the Sesquioxide. The Sulphate, being soluble, is found in some mineral waters. It is also made artificially on a large scale for use in the arts by exposing moistened Pyrites to the air, and is called Copperas or Green Vitriol.

(4524) IRON WOOD.

Yserhout, DUT.	Legno di ferro. IT.
Bois de fer, FR.	Lignum ferreum, LAT.
Eisenholz, GER.	Plohierro. SP.

Iron wood is a term applied to a great variety of woods, in consequence of their hardness, and almost every country has an iron-wood of its own.—*Holtz :* The product of an evergreen tree (*Sideroxylon*), remarkable for the hardness and weight of its timber, which sinks in water, receives this name : it is of a reddish cast, and corrodes like iron. The tree grows chiefly in the West India islands, and is likewise very common in South America, and in some parts of Asia.—*Faulkner. Mesua ferrea*, which has received its specific name from the hardness of its wood, is a native of the peninsulas of India and Malacca and of the islands, and perhas M. pedunculata, furnishes part of the timber known under this name. *Metrosideros vera* is called true iron-wood : the Chinese are said to make their rudders and anchors of it, and among the Japanese it is so scarce and valuable, that it is only allowed to be manufactured for the service of their king. The iron-wood of southern China is *Baryxylum rufum ;* of the island of Bourbon, *Stadmannia Sideroxylon*, and of the Cape of Good Hope, *Sideroxylon, milanophleum*, which latter is very hard, close grained, and sinks in water. The Ceylonese also have an Iron-wood tree—and in Tenasserim the term is also applied to the wood of Inga Xylocarpa ; and of a species of Diospyros. The iron-wood of Guiana is *Robinia Panacoco* (of Aublet), that of Jamaica is *Tagara Pterota*, and also *Erythroxylon areolatum*, which is also called red-wood. *Agiphila martinicensis* and *Cocaloba latifolia*, are other West Indian

trees, to the woods of which the name of iron-wood has been applied, *Ostrya virginica*, called American hop horn beam, has wood exceedingly hard and heavy, whence it is generally called iron-wood in America, and in some places lever-wood.—*Holtzappfell. Tredg.*

(4525) ISARMEL, Aristolochia Indica.—*Ben. Ph.* 209.

(4526) ISATIS, a genus of Plants belonging to the natural order *Cruciferæ* and the tribe *Isatideæ*. It has a laterally compressed pouch, 1-celled, 1-seeded, valves keeled, eventually separating.—*Eng. Cyc.*

(4527) ISATIS INDIGOTICA. In China, coloring matter for dyeing blue, is derived from two species of plants, the *Polygonum tinctorium* at the South, and the *tien tsing* or *Isatis indigotica*, cultivated at Shanghai and Chusan. *Williams' Middle Kingdom, vol.* 2, *p.*105. The Shanghae indigo (Isatis indigotica) is largely cultivated in the Ke-wang-meow district, a few miles to the south.

(4528) ISATIS TINCTORIA, Dyers-Woad.

(4529) ISCARASEE WOOD.

Iscarasee kurra, Tel.

(4530) ISINGLASS. Fish Sounds; Fish Maws; Air Bladder. Swim. Brief scientific notices were given of this article of commerce, under the head Air Bladder, Fish-maws, Gelatine, and Ichthyocolla, and allusion was made to this being the source of isinglass: but with the commercial article it is desirable that more extended observations should be furnished. It was long unknown to the European capitalists of the East what substance was meant by that so largely imported into China as Fish-maws, but after much correspondence, to Dr. Royle is due the credit of ascertaining that Fish-maws are Fish Sounds and Isinglass. The late Dr. Malcolmson of Bombay furnished him with some specimens of different sizes of the Bombay Fish-maws. On examination, these proved to be composed of a sac-like membrane, which had been slit open; some were small, thin, and transparent, others three and four inches across in both diameters, something of the shape of short purses with spring clasps, of a light colour, and semi-transparent;—resembling the ordinary qualities of Isinglass, especially some of the Brazilian kinds, in appearance. On submitting these to Mr. Yarrell, he pronounced both kinds to be the sound of a Fish which he thought might perhaps be the same species, but at different ages, and that it was apparently allied to the Gurnards, and it is interesting here to observe, Cuvier mentions that, in India there are species allied to Trigla hirundo (or the sapphirine Gurnard). Fish-maws are therefore Fish sounds, and have long been carried away by the Chinese from the vicinity of Calcutta, at the rate of about a shilling a pound, without any one being apparently aware of that fact. In Bombay also a commerce has long been established in Fish-maws, at about double the price of the former, without its being generally known that it was Isinglass which was thus exported, and Madras shares in the Trade. The Chinese, therefore, obtain from India, what Europe imports from Russia and Brazil, and in this respect exhibit no greater strangeness of taste than Europeans do. For they give only about the same price (£14) which is obtained in the London Market for Isinglass of the same quality, while we give as much as between £60 and £70 for the best kind and between £90 and £100 when we require this for consumption. Dr. Royle's consultation of the official accounts of the export and imports from the three Indian presidencies showed that not less than to the value of nearly forty thousand pounds of shark fins and Fish-maws was exported in one year from Bombay to China, being first imported from a great variety of places and sold at

From	90	to	105	Rs.per maund	in	1836-37

The Exports being to Bombay, United Kingdom and Malacca Straits. But the greater portion doubtless finds its way to China. The fondness of the Chinese for all gelatinous substances is well known, and has been described by all those who have visited their country and partaken of their banquets. In addition to employing animals and parts of animals which are rejected in other countries as articles of diet, they import various substances which can be valuable only as yielding Gelatine of different degrees of purity. Of these we have examples in Agar-Agar, Tripang, Birds-nests, Sharks-fins, and Fish-maws, among these we may explain that the Agar-Agar, is a species of Fucus or sea weed exported from the islands of the Indian Archipelago as a portion of the cargo of every junk. It forms a gelatinous mass with water to which the Chinese add Sugar and use it as a sweetmeat. *Gracillaria tenax*, —another sea-weed is imported in large quantities into Canton from the Coasts of Fo-Hein and Tchekiang and is supposd to be an ingredient of the Chin-chow glue or Jelly. *Gracillaria lichenoides*, a species of sea-weed, a native of Ceylon, as also of a gelatinous nature, and after being washed in fresh water and pressed to remove the salt and some mucilage is employed as a preserve. This is thought to be the substance which by some is incorrectly considered to be a species of Gelidium and by others the spawn of fish floating on the surface of the sea, made use of by the Salangana or Esculent swallows in constructing their nests which are so highly esteemed by the Chinese : that appears however to be a viscous secretion of the salivary glands of the mouth and stomach of the bird, like what is observed hanging from the bill of the common swallow. The nests, Mr. Crawfurd remarks, both in external appearance and consistence, resemble a fibrous ill-concocted Isinglass. At all events, the best kinds are sold for about £5 18s 1½d per pound, and even as high as 4,200 Spanish Dollars per picul, the last, therefore, are more valuable than their weight in silver. Mr. Crawfurd calculates that not less than 242,400 lbs. of different qualities (white, middling, and black) are yearly imported from the Indian Islands into China. Brandt and Ratzeburg describe the swimming bladder as consisting of three membranes, the outer or peritoneal coat, the middle membranous and muscular one, and the inner, glossy, highly vascular coat, which has a pulpy appearance and is the membrane which forms the best Isinglass. The species of fish which yield the European supplies are the Great Sturgeon, Osseter, Sevruga and Sterlet, also the Silurus Glanis, Barbil, Cyprinus Brama and Carpio and Perca lucioperca, which do not belong to the tribe of sturgeons. In the fisheries of the Caspian and Volga, where the system is most complete and the division of labour the greatest, the Sounds and Roes are extracted immediately the fish are caught and delivered over to the Isinglass and to the Caviare makers. The fresh sounds are first split open and well washed to separate the blood and any adhering extraneous matter (on the Lake Baikal, warm water is used according to Georgi); they are then spread out, and exposed to the air to dry, with the inner silvery white membrane turned upwards. This which is nearly pure Gelatine, is carefully stript off, laid in damp cloths and left in the outer covering, and forcibly kneaded with the hands. It is then taken out of the cloths, dried in the form of Leaf Isinglass, or rolled up and drawn in a Serpentine manner into the form of a heart, horse-shoe, or lyre (long and short staple), between three pegs on a board covered with them ; here they are fixed in their places by wooden skewers. When they are somewhat dried thus, they are hung on lines in the shade till their moisture is entirely dissipated. The oblong pieces sometimes are folden in the form of Book Isinglass. In order to obtain good Isinglass, it is necessary to have well-arranged rooms to dry it in, as at Astrakhan. But it is not alone isinglass which is obtained from Fish-Sounds. There is no doubt, according to Pallas even, that at the lower parts of the Volga, a fine Gelatine is boiled out of the fresh swimming-

bladder, and then poured into all kinds of forms. In Gurief, a fine boiled Fish-glue is prepared, perfectly transparent, having the colour of amber, which is cast into slabs and plates. The Ostiaks also boil their Fish-glue in a kettle. The common Cake Isinglass is formed of the fragments of the other sorts, these are put into a flat metallic pan, with a very little water, and heated just enough to make the parts cohere like a pancake, when it is dried. Parts of the sounds of Silurus Glanis and Barbel are also boiled, but as the glue does not entirely dissolve, the liquid is strained to separate filaments from the Gelatine. Besides these the cartilaginous and tendinous part of several fishes are boiled down to form Fish-glue. Isinglass being prepared from the Swimming-bladder of certain fishes and this being an organ generally though not universally possessed by that class of the animal kingdom, it seems remarkable that it should not be more generally employed for the purpose of yielding so valuable a commercial article. For though Isinglass of the finest quality, and in the largest quantities, is yielded by, it is not confined to, the sturgeon tribe; for even in Russia, the Silurus Glanis, species of Cyprinus, and Barbel yield it and we meet in commerce with Brazilian, New York, and Hudson's Bay Isinglass. The fishes which produce it on the coast of Brazil, have not been ascertained. Camera supposed them to be species of Gadus. Mr. Yarrell informed Dr. Royle that no species of Gadus is caught on the coast of Brazil. The common cod prefers water of a low temperature; though found all the year about Boston, it migrates northward from New York when warm weather begins. The fishes producing Isinglass in Brazil, he further writes, are probably species of the genera Pimelodus and Silurus, or of closely allied genera. The Brazilian Isinglass is imported from Para and Maranham. It is very inferior in quality for domestic purposes to the best imported from Russia, which sells for 12s. per lb. and the other from about 3s. to 3s. 6d. and even as low as 9d. per lb. It is in the form of Pipe, Block, Honeycomb, Cake, and Tongue Isinglass, the last formed of a double swimming-bladder. The specimens shewn to Mr. Yarrell appeared to him to belong to seven different species of Fish. The Isinglass obtained from North America in the form of long ribbons, is produced, according to Dr. Mitchill, by Labrus squeateague, at New York, called weak fish, which is about fifteen inches in length, and above six pounds in weight, forming one of their most abundant fish and furnishing the principal supply for their tables. One author states that its thick silvery swimming bladders are pressed, and another that the sounds of the Hake (Merlucius vulgaris) are also pressed between iron or wooden rollers to form thin Isinglass.—*Royle on Isinglass, pages* 21, 22. The Labrus Squeateague is Otolithus regalis of Cuvier (the Johnius regalis of *Block*), of the tribe Sciænoides. These are allied to the Perches, but have more variety and a more complicated structure in their natatory bladders; almost all are good for eating, and many of superior flavour. To the genus Otolithus also belong some indian fishes, as O. versicolor, Cuv. and O. ruber, Cuv., the peche pierre of Pondicherry, called there "panan," which is fifteen inches long and caught in abundance all the year, being esteemed as food. This genus is closely allied to Sciæna, of which, species, as S. Aquila (maigre of the French, and umbrina of the Romans), &c, are found in the Mediterranean. S. Pama or Bola Pama of Buchanan resembles the "maigres," but has a singular natatory bladder. When twelve or fifteen inches long, it is erroneously called whiting at Calcutta, and furnishes a light and salubrious diet. It is caught in great abundance at the mouths of the Ganges, but never ascends higher than the tide. In New England, the intestine of the common Cod (Morrhua vulgaris) are cut into ribbon Isinglass; in Iceland also the Cod is said to yield Isinglass, so also the Ling (Lota Molva), but Mr. Yarrell informed Dr. Royle that he had no reason to believe that Isinglass is so prepared. At least in the southern parts of England fish being brought alive in well-boats as far as possible, cod and also ling sounds are mostly preserved soft, by salting, and are dressed for table as substitute for fish. Hence we see that Isinglass is not confined to the tribe of Sturgeons, nor to the rivers of Russia, but that it is found in fishes on the warm coast of Brazil and the cold one of Iceland. It is also yielded by some of the great variety and shoals of fishes, on the long extended coasts of Eastern and Southern Asia, and some quantities are imported into Britain. A trade in Isinglass, and in some of its substitutes, has long been established on the coast of India and it has long been imported by the Chinese from Bengal. Indeed on investigating the subject, the discovery was made that Isinglass is exported in much larger quantities and from a much greater variety of places than is generally supposed. So large a quantity as 800 or 900 maunds of the sounds of Fish, that is of Isinglass being annually exported to China from the neighbourhood of Calcutta. The first who appears to have drawn attention to this subject was an anonymous correspondent in 1839, who stated, that the Chinese had long been engaged in a trade with Calcutta in Isinglass. Also that this was afforded by a fish called "sulleah" in Bengal, and that from a half a pound to three-quarters of a pound was obtained from each fish. This information was energetically followed up by Mr. McClelland of the Bengal Medical Service. The curing of fish had been previously suggested by Dr. Cantor of the same service. Mr. McClelland's first paper

was published at Calcutta in June 1839, in the Journal of the Asiatic Society, vol. VIII. p. 203. In this he informs us, that having procured a specimen, from the bazar, of the fish yielding the Isinglass, he was surprised to find it to be a species of Polynemus, or paradise fish, of which several species are known for their excellence as articles of food. Of these he adduces the Mango Fish or tupsee mutchee of the Bengalees (Polynemus Risua, Buch.) as a familiar instance, though this is remarkable as being without a swimming-bladder; while the other species have it large and stout. These occur in the seas of warm climates; five are described by Dr. Buchanan in his Gangetic fishes, but only two are of considerable size, occurring in the estuary of the Hoogly, and probably in those of the Ganges. One of these, with another large species, is also described by Dr. Russell in his work on the fishes of the Madras Coast. That figured in tab. 184 and called maga-booshy is Polynemus uronemus of Cuvier, while the maga-jellee, tab. 183, named P. tetradactylus by Shaw is probably P. Teria of Buchanan. Both, but especially the first, Russell says, are esteemed for the table and called Roeball by the English. Mr. McClelland ascertained that the species affording the Isinglass, is the Polynemus Sele of Buchanan, Sele or Sulea of the Bengalese, described but not figured in his work on the Gangetic fishes (p. 226). Mr. M. has however published in the Journal of the Asiatic Society of Bengal, a figure from Dr. Buchanan's unpublished collection of drawings, which are kept at the East India Company's Botanic Garden at Calcutta. This figure, he states, conveys a good representation of the Sele, about half the size of a specimen, from which he obtained sixty-six grains of Isinglass. Dr. Buchanan describes the Sele as affording a light nourishing food, like most of the fishes which he has called Bola, but as inferior to many of them in flavour. It is common in the estuaries of the Ganges, and is often found weighing from twenty to twenty-four pounds; and may perhaps be the Emoi of Otaheiti, the Polynemus lineatus of Lacepede, the P. plebeius of Broussonet. This, according to Block, is by the English called king-fish, and is the Kala mine, *Tam.* of John, from Tranquebar, and abundant in the Kistnah and Godavery. Buchanan further states, that the Sele has a stroug resemblance to the above named "maga,booshee" of Dr. Russell. As the anonymous author above referred to, stated that from half a pound to three quarters of a pound may be obtained from each fish. Mr. McClelland supposed either that P. Sele attains a much larger size than twenty-four pounds, the limit given to it by Buchanan, or that Isinglass is also afforded by a far larger species, namely, P. tetradactylus, Telia, or teriya bhangan. This, as we have seen, is identical with the "maga-jellee" of the Coromandel Coast, and which Buchanan often saw six feet long in the Calcutta bazar, and was informed, it sometimes equalled 320 pounds avoirdupois in weight. It is considered by the natives as a wholesome diet although seldom used by Europeans. Mr. McClelland says he has frequently seen them of a uniform size, that must have weighed from fifty to a hundred pounds at least, loading whole cavalcades of carts on their way to the Calcutta bazar during the cold season. Both the Sele and the "teria bhangan" must consequently be very common there from November to March. *P. Sele* is supposed to be a variety of *P. lineatus*, which is said to be common on all the shores to the eastward; but if so, Mr. M. says, it seems strange that the Chinese should send for it to the Hoogly. The same might, however, be said of the Cod, which, though caught in abundance on the coasts of Great Britain, is also diligently sought for on the banks of Newfoundland. He also inquires whether Polynemus Emoi and P. plebeius, supposed by Buchanan to correspond with his Sele, contain the same valuable substance, and whether either of Russell's species, the above named maga-booshee and maga-jellee (*Indian fishes*, 183-184), yield it.—*Royle on Isinglass, passim.* It will have been seen that Isinglass is the air-bag, or swimming-bladder, sometimes called the sound, of various fish, chiefly of the sturgeon tribe, and belonging to the genus Acipenser. This bag is a membrane filled with air, situated near the spine, above the centre of gravity. In most fish it communicates with the æsophagus, or stomach by a duct, which is known as the ductus pneumaticus, in others the duct is imperforate; occasionally there are two sacs, one anterior to the other, and communicating by a short tube. The air-bag is made up of an external or peritoneal covering a middle fibrous, and in some cases muscular coat, and an internal, highly vascular membrane. This is called also the Air Bag, Swim, or Sound. It is a peculiar organ with which the great majority of fishes are provided, and by which they are enabled to adapt the specific gravity of their bodies to the various pressures of the superincumbent water at different depths, It is composed of a lengthened sac, sometimes simple, as in the common perch, sometimes divided into two or more compartments, by a lateral or transverse ligature, as in the trout and salmon, and, at other times furnished with appendices, more or less numerous according to the particular species. In all cases, it is composed of a thick internal coat of a fibrous texture, and of a very thin external coat; the whole being enveloped in the general covering of the intestines. Although it does not appear that the air-bladder is connected with the function of respiration in fishes, it occupies the position, and has the same relations, as the lungs in reptiles. It is in fact, the homologue of these organs. Fishermen are well acquainted with the nature

and functions of the air-bladder. They are accustomed to perforate this vessel with a fine needle in cod and other species which require to be brought fresh to market, sometimes from a very great distance. By this operation, the confined air is allowed to escape, and the fish constrained to remain quiet at the bottom of their well-boats, where they live for a very considerable period. The Cod sounds, brought into Britain in great quantities from Newfoundland, are the salted air-bladders of these fishes. They are also largely imported into England from the East Coast of Scotland. The Iceland fishermen, as well as those of America, prepare isiaglass of a very excellent quality from cod-sounds, though they are not acquainted with the method of clarifying it, which the Russians practise in preparing isinglass from the sound of the sturgeon — *Eng. Cyc. p.* 103. Russian Isinglass is prepared from the sounds of the Sturgeon *Accipenser sturio*, found in the Caspian and Black Seas and their tributary rivers. In America, from the *Labrus squeteague*, the intestines of the cod, *Morrhua vulgaris:* and in Calcutta, from the sounds of the Polynemus Sela, the *Sulea* of Bengal.—*O'Shaughnessy, page* 685. The sounds of two Madras fish are so employed. The following are the principal species of fish from which Russian isinglass is derived—Acipenser Huso or the Beluga, A. Gouldenstadtii or the Osseter, A. Ruthenus or the sterlet, A. stellatus or the Sewruga Silurus Glanis and Ciprinus carpio. In addition to the above isinglass is obtained in different parts of the world from several other kinds of fish. In New York from the Labrus squeteague of Mitchel. In New England it is procured from the intestines of Morhua vulgaris or the common cod. In the Brazils it is obtained from a large fish, probably a species of Silurus, and in Iceland from the cod and Lota Moloa or Ling. *Isinglass, Fish Maws, Fish-sonds, or Air-Bladders.* (*Palogpong ikan* or *ari ari ikan* of the Malays, *loo-pa* of the Chinese) appear to have formed an article of exportation from the islands of the Indian Archipelago as early as they became visited by the Chinese. When these people commenced to settle in the Straits, they not only there collected fishmaws but also from distant localities. Bombay, Ceylon, Madras, Bengal, Tenasserim and most of the Malayan Islands contribute to the annual supply, which is bought up by Chinese dealers at Penang, Malacca, and Singapore. By them the Maws are exported to China. The fact was noted by Mr. Crawfurd, but that the Fish maws are isinglass, appears to have been the discovery of an anonymous correspondent in Parbury's *Oriental Herald* for January 1839. The personal exertions of Mr. McClelland have been mainly instrumental in adding isinglass to the articles of exportation from India to the European Markets. Since 1842, Mr. W. T. Lewis, Assistant Resident Counsellor of Pinang, has made some very successful attempts to improve the production of isinglass in Prince of Wales Island. But European Merchants there appear unwilling to engage in this novel branch of commerce, as the supply from want of proper care is uncertain, and procurable but in comparatively small quantities. These, however, are no objections to the Chinese dealers, as they are sure of a profitable and quick return of their outlay. The fishes from which isinglass is obtained at Pinang are,

Lates keptadactylus, (*Ikan siyakup.*)
Polynemus indicus, (*Ikan kurow.*)
Otolithus biauritus, (*Ikan salampae.*)
Otolithus ruber, (*Jarang gigi.*)

The fishes of Eastern and Southern Asia, from which Isinglass is prepared have been described at length under the head of Fish-Sounds; and it is here necessary merely to mention that on the Malabar Coast, excellent Isinglass is obtained from two species of Otolithus. One, perhaps the *O. biauritus*, Cantor, is named in Malayalim "*Sille korra*," it grows to a large size and is highly prized for the Isinglass it yields; the *O. ruber*, also yields good Isinglass. Mr. Mason also describes the Corvinus coitor, or Indian Whiting, and the Polynemus sele as yielding this substance in Tenasserim. He says, of Indian Whiting, there are two or three species of fish common in Calcutta that are called whiting, from their resemblance, both in form and flavour, to the European fish of that name. One species is frequently seen in the Maulmain bazars, and besides being a good fish for the table, its air-bladder makes excellent isinglass. He thinks he has observed more species than one sold under the same native name, but the specimen he sent Mr. Blyth he said was *Corvinus coitor.—Mason.*

King-fish.—Polynemus sele, Buch; *plebeius*, Brouss; *lineatus*, Lacep; *gelatinosus*, McClell; *ka-tha* (*the young,*) O'Riley; *lukwah* (*Arracan,*)

Bogle. *Emoy*, Otaheite A few years ago the attention of the Commissioners of the Tenasserim Provinces and Arracan was drawn to the fish that produce isinglass; and the result was, the discovery on their shores of the species of Indian whiting noticed above, and *Polynemus sele*, a fish that is found from Calcutta to Otaheite. The polynemus produces isinglass of the best quality, and Mr. O'Riley estimated that two thousand pounds might be obtained annually off Amherst alone. None of their merchants have yet entered into the isinglass speculation, but the sounds are a constant article of traffic among the Chinese. Mr. Blundell said the largest sounds were exported from Rangoon, and that they sell here at about half a rupee a pound; and Major Bogle wrote, that about ten thousand of the fish, large and small, were taken annually in Arracan, and that the sounds sold there for about a third of a rupee per pound to the Chinese, who exported them to Penang, where they are said to bring more than a rupee a pound. The specimens that have been prepared in India for the European market, are "complained of," says Dr. M'Clelland, "as being too thick, if intended to come into competition with the superior varieties of Russian isinglass. The first quantities sent from India brought only 1*s.* 7*d.*, others have been sold for 3*s.*, and a few samples have been valued at 4*s.* per pound."—*Mason.* Isinglass has long been exported from India to various countries. According to Mr. Jerdon and Dr. Cantor, the following are the more important of the fishes, which produce Isinglass on the coasts of Eastern and Southern Asia.

(4531) *Arius arius.* (Buchanan Humilton,)
SYN. Pimelodus arius (Buch. Ham.)
Ikan Saladu or Surdudu, Malay,

Total length 1 foot; 10 inch. This fish Inhabits Sea and estuaries of Penang: Malayan Peninsula, Singapore, Pondicherry and Gangetic estuaries. At Penang small individuals of this species are very numerous, at all seasons. They form an article of food, and contribute more than any other, of the Siluroidœ, to the exportation of Isinglass.—*Cantor* 1241.

(4532) *Arius militaris.* (Linne).
SYN. Silurus militaris, Linne.
Osteo-geneiosus, Bleeker.

Length 1 foot, 6 inch. Inhabits the Sea and estuaries of the Malayan peninsula, and of its islands, of Malabar, the Ganges and Irawaddy: also Coromandel. Their air vessels are preserved.

(4533) *Arius truncatus*, Cuv. and Val, Length, 11⅛ inch inhabits sea and estuaries of Penang, Malayan Peninsula. Its air vessel is small but very thick; transversely divided into two compartments. The fish is held in esteem by the natives, but at Penang it occurs so rarely that its air-vessel does not contribute much to the general stock of Isinglass.—*Cantor, p.* 1240.

(4534) *Capoeta macrolepidata*, Kuhl. Length 11 Inches. Inhabits Penang, Java and Tenasserim, (fresh water). The air-vessel is very large, thin, white, consisting of two elongated oval portions, of which the anterior is truncated in front.—*Cantor, p.* 1250.

(4535) *Corvinus coitor*, Blyth. Inhabits the estuaries of the Ganges and Irawaddy. Its air-bladder makes excellent Isinglass.—*Mason, page* 303.

(4536) *Corvinus chaptis*, Balo chaptis. The Bola. Inhabits the Malay coast: furnishes isinglass.—*Mason, p.* 303.

(4537) *Johnius maculatus*, Bloch, Schneider, var?

SYN. Sari Kulla, TAM., Russell.
Corvina maculata, Cuv. and Val.

Total inches? Inhabits Sea of Penang. The form of its air vessel resembles that of Johnius belengeri.—*Cantor, p.* 1051.

(4238) *Johnius Dussumieri*, Cuv. and Val.

SYN. Corvina dussumieri, Cuv. and Val.

The total length of this fish is 6⅘ inches. It inhabits the Sea of Penang, the Malayan Peninsula, Singapore and Malabar. The length of the air vessel is about ¼ the total length. The isinglass is reputed good, but owing to the small size of the fish little is procurable.—*Cantor, p.* 1047.

(4539) *Johnius diacanthus*, (Lacepede).

SYN. Lutjanus diacant'us, Lacep.
Johnius catalens, Cuv.
Sciæna maculata, Cuv. and Val.
Corvina catulea, Belanger and Bleeker.
Nalla Katchelee, Russell. Katchelee, Russell.
Corvina nalla Katchelee, Richardson.
Ikan Tambareh, Malay.

This fish grows to 2 feet 9 inches. It inhabits the sea of Penang, Malayan Peninsula, Singapore, Malabar, Coromandel, Bay of Bengal, Gangetic estuaries, Tenasserim, Canton, China seas, Madura and Java. The *air*-vessel, ⅓d of the length of the fish, is of a broad lanceolate shape tapering behind into a very elongated point. This fish is not only valuable as an article of food, but also on account of the quantity and quality of its isinglass, which sells in the China market at from 40 to 45 Spanish dollars per pecul.—*Cantor, page* 1050.

(4540) *Lates heptadactylus*, (Lacepede.)

SYN. Perca maxima, Sonnerat.
Holocentre heptadactyle. Lacepede.
Pandoo menoo, Russell.
Coius vacti. Ham.
Lates nobilis, Cuv. and Val: Richardson and Bleckeer.
Ikyan Siyakup, Malay.

The total length is? This fish inhabits the sea and estuaries of Penang, Malayan Peninsula

and Singapore. Jerdon also describes the L. nobilis at Madras. It yields isinglass, of which however in the straits of Malacca, but little is collected, partly on account of the comparative scarcity of the fish and partly owing to the thinness of the air-vessel. That of a fish when dried, weighs upwards of one ounce. At Penang this kind sells at the rate of 25 to 30 dollars per pecul.—*Cantor.*

(4541) *Lobotes erate*, Cuv. and Val.

Syn. L. Farkarii, Cuv. and Val.
Ikan batu, or Ikan pichat priek, Malay.

Total length 2 feet 5 inches. It inhabits Sea of Penang, Malayan Peninsula, Singapore, Java, Madura, Malabar, Ceylon, Bay of Bengal, and estuaries of the Ganges. The air-vessel is very large, about ⅓ of the total length, silvery white and of a lanceolate shape. It is excessively thin and so firmly adhering to the back, that but a small part can be removed. The isinglass is by the Chinese dealers considered to be of good quality, but the small quantity procurable renders the fish less valuable in this respect,--*Cantor*, *p.* 1061.

(4542) *Mugil Cephalotus*, Cuv. and Val.

Syn. Mugil our, Forskal.
Jumpul, Malay.
M. Cephalus, Russell.
Boutali, Tam, Russell.
Sole bhauggan. Ham.

Total length, 2 feet. It inhabits, Penang, Malayan peninsula, Singapore, Macao, Lancavy, Chusan, Madura, Coromandel, Bay of Bengal; Gangetic Estuaries, Malabar. The air-vessel is large, elongated, its parietes very thin, pearl-coloured.—*Cantor*, p. 1076.

(4543) *Otolithus*, Sp., perhaps *O. biauritus of Cantor.*

Syn. Sille-kora, Malayalum.

This fish grows to a large size. It is found on the Malabar coast, and highly prized for the isinglass it yields.—*Jerdon.*

(4544) *Otolithus biauritus*, Cantor. Total length: 3 feet. Inhabits Sea of Penang, Malayan Peninsula, Singapore, Lancavy, Tenasserim Provinces, and according to Jerdon, the Malabar coast, where it is called Sille-kora, in Malayalim. The air-vessel is nearly one half of the total length, and in shape might be compared with an elongated antique urn with two handles. From the anterior part of each of the latter proceed five branches, four of which give off smaller ones to each side, and the fifth is tortuous and smaller than the rest. It yields a large quantity of isinglass, which in the Chinese market is considered to be of the best quality, and fetches 40 to 50 Spanish dollars per pecul.—*Cantor*, *p.* 1041.

(4545) *Otolithus ruber*, Bloch and Schneider.

Syn. Jaran-gigi, Malay.

The total length of this fish is 2 feet, 6 inches. It inhabits the Sea and Estuaries of Penang, the Malayan Peninsula, Singapore, Coromandel and Malabar. The air-vessel is large, flattened, broad lanceolate, terminating behind in a single point. The isinglass is considered very good and sells in the Chinese market from 40 to 45 Spanish dollars per pecul.—*Cantor*, *p.* 1043.

(4546) *Otolithus maculatus*, Kuhl. and Van Hasselt.

Syn. Jaran gigi, Malay.

The total length of this fish is 2 feet 9 inches. It inhabits the Sea and Estuaries of Penang, the Malayan Peninsula, Singapore and Batavia. It is highly valued for the sake of its air-vessel, which yields a considerable quantity of the best kind of isinglass.—*Cantor*, *p* 1045.

(4547) *Otolithus versicolor*, Cuv. and Val. The total length of this fish is only 6½ inch. It inhabits the Sea of Penang. Its air-vessel is ¼ of the total length.—*Cantor*, *p* 1046. *Otolithus versicolor.* Cuv. and Valen: Russell, 109. Panna *Tam.* This fish is one foot long and very common at Madras.—*Jerdon.*

(4548) *Pempheris molucca*, Cuv. Length 3⅜ inch. Inhabits sea of Penang, Moluccas, Batavia and Japan. Its air-vessel is large and thick. —*Cantor*, 1158.

(4549) *Pempheris molucca*, Cuv. This fish grows to 3⅜ inches. It inhabits the Sea of Penang, the Moluccas, Batavia and Japan. Its air-vessel is large and thick.—*Cantor*, *p.* 1158.

(4550) *Platax arthriticus.* Cuv. and Val.

Syn. Ecan bonna, Bell.
Chœtodon arthriticus, Cuv. and Val.

The total length of this fish is 1 foot, 7 inches. It inhabits the Sea of Penang, Sumatra, Java and Singapore. The flavour is excellent, but the large air-vessel is too thin, and yields too little isinglass to become of value.—*Cantor.* *page* 1152.

(4551) *Polynemus.* The species of this genus, furnish a considerable portion of the isinglass of Southern and Eastern Asia.

(4552) *Polynemus hepiadactylus.* Total length 4⅜ inches. Inhabits Penang, Batavia, Cheribon and Samarang.—*Cantor.*

(4523) *Polynemus indicus*, Shaw.

Roe-ball, Eng. | Ikan kurow, Mala.
Walan kala, Tam. | King Fish, Eng.

Syn. P. Sele, Buchanan.
P. uronemus, Cuv. and Val.
P. ploteus, McClelland.
P. lineatus, McClelland.
P. gelatinosus, McClelland.
Ka-tha, the young, Burmese; Lukwah, Arracan.

The total length of this fish is 3 feet. It inhabits the Sea of Penang, Singapore, Malayan peninsula, Surabaya; Estuaries of the Ganges;

Vizagapatam; Madras and Pondicherry. The structure of the air-vessel of this species is the most striking character by which it may at once be distinguished from P. plebius. Its membrane is silvery thick; the general form oval. It occupies the whole length of the stomach terminating behind in a very sharp point, which penetrates the thick of the tail over the first interspinal of the anal. At Penang single individuals occur at all seasons: but numbers are taken from June to August. The weight is commonly from 4 to 6 lb. seldom exceeding 20. The air-vessel of a good sized fish, when dried and ready for the market in China, weighs upwards of 2 oz., is considered very good isinglass, and fetches 25 to 30 dollars per pecul. The fish itself is valued as an article of food, though less so than P. tetradactylus.—*Cantor*, Mr. O'Riley estimated that 2000 lbs. of isinglass from this fish, might be obtained annually off Amherst alone.—*Mason*, *p.* 304. Mr. Blundell said that the largest sounds were exported from Rangoon, and that they sell there at about half a rupee a pound. Major Bogle wrote that about 10,000 of the fish, large and small, were taken annually in Arracan and that the sounds sold there for about a third of a rupee per pound to the Chinese, who exported them to Penang where they are said to bring more than a rupee a pound.

(4554) *Polynemus plebius*, Broussonet: Linne Bloch; Shaw; Cuv. and Val.

Roe-ball, Eng. | Pole kala, Tam.
Syn. P. lineatus, Lacepede.
P. niloticus, Shaw.
P. commersonii, Shaw.
Bynni, Bruce.

This fish attains to 4 feet as its full size. It inhabits, Coromandel coast, Otaheite, Isle of France and Isle of Tanna. Its value as a fish yielding isinglass requires to be ascertained.—*Cantor.*

(4555) *Polynemus sextarius*, Bloch-Schneider. This fish is only four inches long. It inhabits Penang, Batavia, Tranquebar and Coromandel. Its air-vessel is minute, being of the shape and size of a grain of oats.—*Cantor.*

(4556) *Polynemus hexanemus* Cuv. and Val. 4 inches long. Inhabits Penang, Batavia, Samarang and Pasuruan.—*Cantor.*

(4557) *Polynemus tetradactylus*, Shaw.

Roe-ball, Eng. | Yerra kala, Tam.
Syn. Polynemus teria. Gray.
Triglia asiatica, Linne.
P. salliah Cantor.
P. quadrifilis, Cantor.
Maga jelle, Russell.

Inhabits Penang, Singapore, Malayan Peninsula, Lancavy, Bay of Bengal, Gangetic estuaries; Australia; China: Bantam; Batavia; Tjilatjap; Samarang; Surabaya: Bangkallang. This species has no air-vessel.

(4558) *Pristipoma Guoraca*, Cuv. and Val.

Syn. Perca grunniens, Forster.
Anthias grunniens, Bloch-Schneider.
Guoraka, Russell.

This fish is one foot long. It inhabits the Isle of Tanna, Batavia, Coromandel and Mahe (fresh water). Its air-vessel is very thin, from which its isinglass is of little value.—*Cantor*, *p.* 1056.

(4559) *Umbrina Russelli*, Cuv. and Val. Richardson.

Syn. Qualar Katchelee, Tam: Russell.
Ikan gulama, Malay.

Total length 6 inches to one foot? Inhabits Sea of Penang, Malayan Peninsula, Singapore, Vizagapatam; Indian and China Seas. Its isinglass is considered of good quality.—*Cantor.* Good Isinglass is generally described as being one of the purest forms of Gelatine we are acquainted with, it consists, in fact, of little else besides, and accordingly presents very nearly the characters of that substance. The properties of pure Isinglass or Gelatine are briefly the following. It is transparent and colourless or nearly so, inodorous, tasteless, and of a hard or horny consistence. It is but little hygrometric, remaining tolerably dry in ordinary conditions of the atmosphere. In cold water, it gradually softens and swells up; in hot water, it easily dissolves, and forms a clear solution, which if it contain as much as a $\frac{1}{100}$th part of its weight of Gelatine, has the property of gelatinizing or assuming the form of a soft tremulous solid as it cools. Dry Gelatine is a permanent and unchangeable substance, but in solution it is very liable to undergo decomposition becoming mouldy and rapidly putrifying when exposed to the air it has been observed that the ordinary and more impure forms of Gelatine are more liable to undergo this change than the pure substance: the presence of minute quantites af acids, alkalies and other impurities greatly accelerating its decomposition. All Isinglass contains small quantities of Albumen, saline and earthy matter, and a peculiar substance called Ozmazome, the better sorts containing less, and the inferior more of those impurities. The Bengal Isinglass, however, has been found to consist of Gelatine, Albumen, a small portion of saline and earthy substance Ozmazome, and a minute trace of an odorous oil. In the Indian Isinglass, it is probable that its defects are in a great measure to be attributed to a want of sufficient care in its preparation, and it is evident that good Isinglass cannot be made without considerable attention is paid during the processes of washing, beating, scraping, and drying; all of which have a very important influence on the goodness of the finished Isinglass. The imperfect solubility of some, and more especially the thick pieces, is occasioned by the presence of a considerable quantity of Albumen or insoluble

membranous matter having most of the properties of albumen which is not only itself insoluble, but in addition renders much of the Gelatine, with which it is associated, likewise insoluble. It is more than probable that the greater part of this albuminous substance might be readily removed by sufficiently scraping the Isinglass during its preparation. Attention should also be directed to the process of drying, as, if not properly dried, it might possibly undergo a slight change or decomposition, and become partially converted into a more insoluble form of Gelatine. A more important objection is the smell which however may likewise to some extent be traced to the preparation. It is probable that by increased care in cleaning and drying by exposure to air, some of those defects may be removed especially as we shall observe in comparing the two processes, that much greater care is bestowed on the preparation in Russia than in India. Boiling with fresh made charcoal would probably have the effect of depriving inferior Isinglass of some of the smell and colouring matter when required for the purposes of a jelly. The Isinglass cut into threads is unsuitable for the English market, notwithstanding that Isinglass for retail is cut into fine threads, as more convenient for general use, and for making jellies and soups, in consequence of the extensive surface which is exposed rendering it more easily and quickly soluble. But there is a great prejudice in the wholesale market to buying things in a cut or powdered state in consequence of the innumerable methods adopted for falsifying and adulterating almost every drug. Machinery is used in London for cutting the Isinglass into threads of any degree of fineness, and as it is inpracticable at present to rival this in India, besides having to contend against prejudice, if sent in this state, it is preferable, and will be cheaper to prepare the article and send it as sheet Isinglass, that is, the form of the slit sounds themselves, or their purest membrane washed, cleaned, and dried in the best manner. The Indian Isinglass, as at present prepared, is complained of as too thick if intended to come into competition with the superior varieties of Russian Isinglass. Some of it may, without difficulty, be rendered thinner, for even in the dried state, layers of membrane which display a fibrous structure may be stripped off, and which no doubt contain the greater portion of the insoluble Albumen. It might also be made thinner by beating, or pressing between iron rollers or marble slabs, as is done with American and some kinds of Brazilian Isinglass. The extra labor which this would require might be profitably saved, by not tearing it into fibres, in which state it is disapproved of in the market; but it might still be cut or rasped into a state fit for domestic use. The refuse should be turned to account; the soluble parts of the sounds, separated from the insoluble and poured out into thin plates and dried on nets, as is done with some of the Gelatine of commerce. In order to ascertain the value of the article (merely stripped of all impurities calculated to injure its quantity without any regard to appearance) a considerable quantity was sent to England by Dr. McClelland. From the account received of the sale, it appears that this Isinglass realized only 1*s.* 7*d.* per lb., which was considerably under its prime cost. Forty-four maunds and ten seers of Fish Sounds having been bought for forty rupees a maund, required an expense of 100 rupees for cleaning, after purchase from the fishermen, thus costing altogether about 1*s.* 7*d.* per lb. This quantity, or 2,285 lbs., at 1*s.* 7*d.* per lb., realized £176. 18*s.* 8*d*; but the charges in India and in England, consisting of packing, demurrage, freight, insurance, shipping charges export and import duties, warehouse, brokerage, commission, interest &c., were so heavy that the whole did not realize quite one-third of the outlay. One of the cut samples had been bleached, but was of no more value than the one unbleached. Though the first quantities from India brought only 1*s.* 7*d.* others have been sold for 3*s.*, and a few samples have been valued at 4*s.* per lb. Besides this opening for an extensive sale in the European market, even in the present state, we know there is always a constant demand in China for the Isinglass of Bengal. This will no doubt afford sufficient encouragement to persevere in the extension and improvement of this newly established and highly promising article of the export trade of India to Europe. The East Indian will be only available for brewers' use, and then it must be sweeter and of better flavour than the present samples. The Brazil is the description taken by brewers, and is worth 2s. 6d. to 3s. 6d. per lb., but is quite free from the objectionable smell, as is also the Samovy, which is of nearly the same value, and applied to similar purposes. A parcel of East Indian in sheet was sold at public sale in November 1850 at 2s. 6d. per lb., in bond, but it was subsequently supposed it would now bring a higher price. R.W. Barchard, Esq., stated that when the Bengal Isinglass was compared with an equal quantity of Brazilian Isinglass in a brewing establishment where the latter was used, it was found that the Bengal was nearly all dissolved in the usual menstrum (sour beer) some time before the Brazilian. The Bengal Isinglass appeared also to make a much finer and stronger jelly than the other with the advantage of dissolving in about half the time and without unpleasant smell. The inner membrane also of the sturgeon yields the best Isinglass, while in the sele it seems to be rejected. This would account for the more fibrous nature of the Bengal Isinglass, though it does not follow, that in the Sele, the innermost is the best. A decided improvement would be effected if the Isinglass were prepared

as soon as possible after the fish is caught. The Sound should be extracted, split, and more carefully washed (perhaps with lime-water) than the native fishermen are likely to practise, if left to themselves, besides being freely exposed to the air. Some of the Isinglass of commerce has the defect of a fishy smell, as well as of being in part insoluble, while other kinds are made more saleable by the assistance of pressure, and more soluble by the aid of acetic acid. The only legitimate method, however, is to prepare it from the thinner and more gelatinous, and if possible from the inner membrane, as in the Sturgeon. The Isinglass of commerce consists of the sounds simply dried and of a well prepared inner membrane. The Brazilian is composed of the former, and with it the Indian Isinglass is at present able to contend. As both are now only applicable to the purposes of fining the object should be to prepare the Indian of such quality, that it might be applied to all the purposes of the best Isinglass, and thus be able to command the higher, if not the highest prices. Isinglass is brought to market in different forms, sometimes in that of simple plates, at other times rolled up in different shapes or cut into fine threads. When of good quality Isinglass is of a whitish colour, thin and semi-transparent but tough and flexible, destitute of taste as well as smell. Isinglass being mild and unirritating in nature and at the same time nutritious is much employed as an article of diet for the sick and convalescent, and the fine shreds into which it is cut and kept in shops give great facilities for making a jelly in the shortest possible time. This can be made as palatable and nourishing as any by the addition of sugar and milk acids or spice; about one-third or half an ounce is sufficient for a pint of water. It may also be taken in the form of a soup with the addition of salt, spices and sweet herbs, or it may be employed medicinally as an emollient and demulcent either externally or internally. The best kinds of Isinglass are alone employed in articles of diet and for the best confectionary, being added in small quantities to other, especially vegetable jellies, to give them a tremulous appearance. But gelatine is now frequently substituted.—*Royle on Isinglass, p.* 11. Isinglass is also employed in making court-plaster, which in France is called Sparadrap d'Angleterre; it is a thin coating of Isinglass with a little tincture of benzoin spread on black sarcenet. It is also employed for giving a lustre to some kinds of woven fabric; but it is more extensively used for clarifying different liquors such as wine, beer, and coffee than for any other purpose. The inferior kind called cake Isinglass being brownish coloured and having an unpleasant odour is only employed in the arts and for the purposes of glue. The great consumption of Isinglass, necessarily however of the inferior kinds, is chiefly by the brewer in the process of fining. This he effects by the use of Isinglass which he dissolves in sour beer to the consistence of thick mucilage. A little of the solution being added to the liquor to be clarified causes the subsidence of all the suspended matter in the course of a few hours when the liquor remains perfectly transparent. The sounds of cod fish are said to be employed for the same purpose, though the principal import into England is in a salted state for food.—*Royle, p.* 12. Isinglass is the purest form of commercial gelatine. The best is prepared from the air bladders and sounds of three or four species of sturgeon, inhabiting the Black and Caspian seas and their tributary streams. These tissues are cleansed, dried and scraped, forming *leaf isinglass*; or they are twisted into various forms, and called *long* and *short-staple*: or folded into packages called book isinglass. In Russia, from whence the best isinglass is obtained, the swimming bladders of the fish are first placed in hot water, carefully deprived of adhering blood, cut open longitudinally and exposed to the air, with the inner, delicate, silvery membrane upwards. When dried, this fine membrane, is removed by beating and rubbing and the swimming bladder is then made into different forms, and as cut by machinery into the delicate filaments in which it is usually sold. It is a colourless inodorous substance perfectly soluble in hot water and largely consumed as an article of food. It forms a very transparent jelly, and indispensable in the preparation of blanc mange, ices, creams, and other delicacies for dessert. Inferior isinglass answers for fining beer. But for domestic use, the purest and whitest is required, entirely free from unpleasant odour and dissolving readily and completely in warm water. Isinglass has long been made in India, and exported to China, but much of it has an unpleasant, fishy odour, which renders it unfit for culinary purposes. The Caspian and Aral seas yield the various kinds of the genus Acipenser in great abundance: they are also to be found in the waters several hundred miles beyond Astrakhan in the Volga, Yik, Don and even in the rivers as far as Siberia. The fisheries to the extent of three bazens or twenty one feet depth of water belong to the proprietors of the coast. The Hon. Captain Keppel in his "Travels" describes one merchant as holding thirty fisheries, for one only of which at Karmaziack he paid an annual rental of 450,000 roubles.

Method of Preparation. The fish, are taken from the boats with instruments somewhat resembling boat hooks and laid in a row. The head of each fish is then split in two and the caviare and air bladder immediately separated. The latter is at once slit open and placed in cold water. After a short time they are cleaned, divested of a certain outside skin or membrane which envelopes the sounds, nailed to

a board and exposed to the sun to dry. This preparation however has reference only to leaf isinglass. That known as short staple, long staple and book isinglass, has each its distinctive method of preparation. Short staple is formed of a thin Astrakhan isinglass, which is rolled to something under the thickness of a finger or cord and the length varying according to the intended size of the staple. A thin membrane is generally selected for the centre of the roll round which the rest is folded, about half an inch of each extremity being mostly turned inwards ; the two ends of the roll are then drawn together and pinned with a small peg. The middle of the roll being pressed downwards the staple assumes a heart shape and without further preparation it is left to dry. Samovey short staple prepared from an inferior isinglass is likewise imported : indeed this description is received in the three forms of staple leaf and book. The manufacture of long staple varies a little from that just described, the operator lengthens the staple at will by interfolding the ends of the pieces with the portion ready for twisting. The required dimensions being thus attained, the ends are fastened together in the same manner, but it is afterwards subjected to a heavier pressure from the middle ; then in order to preserve the shape of the three obtuse angles consequently formed, a cane or stick about a quarter of an inch in diameter is fastened in each angle with small wooden pegs at each extremity to keep them in position. When sufficiently dried to retain their form, the pegs &c., are removed and on the drying being completed the pieces are colligated in rows by the passing of a string through the peg-holes : this is done for the convenience of package and exportation. The isinglass known as book is of an inferior quality and requires far less preparation. The larger bladders when cut open, cleaned and partly dried, are merely folded up square in the same manner in which book-folding is conducted, a resemblance that points out the origin of its name. It may be asked why all this evidently useless system of preparation is resorted to when much expensive trouble might be dispensed with and the article exported of equal value in its natural and unprepared state. It may be inferred that the system of twisting isinglass into staple or folding it into books was originally practised to disguise the article and keep other nations in the dark as to the source of isinglass. There is however a kind of isinglass exported from St. Petersburg which receives little or no preparation. This description is taken from the silurus glanis and the Ciprinus carpis. These produce the kind of isinglass called purse. It consists of the sounds or swimming bladders dried just as taken from the fish, being neither cut open nor folded but merely dried and collected together by a string passed through the upper part of each bladder. It is gathered together by certain collectors and by them brought to the Irbites fair held in January and February in each year. It is there bought up by the various dealers, cleaned and carried to St. Petersburgh where it arrives during the months of May and July. The entire quantity of Isinglass shipped during the seasons of the past seven years was as follow, viz.

In 1844	the total	amount	shipped	was 5300 poods.
1845	„	„	„	4200 „
1846	„	„	„	5100 „
1847	„	„	„	3600 „
1848	„	„	„	3200 „
1849	„	„	„	4900 „
1850	„	„	„	5100 „

By the above figures it will be seen that the average annual exportation of isinglass from the Russian capital, during the period mentioned, was 4500 poods. The Russian pood being equal to thirty-six English pounds, it follows that 152,000 pounds of isinglass, on the average, are shipped every season (a period seldom lasting more than six months), and that in the course of seven annual seasons, 31,400 poods were exported, a weight equal to one million, one hundred and thirty thousand, four hundred pounds. In addition to the isinglass imported from Russia a vast quantity is annually received from the Brazils, and the East and West Indies. It is, however, greatly inferior to the descriptions we have noticed. Indeed, Brazilian isinglass is only fit for fining purposes, and for such it is almost wholly bought up by the proprietors of large brewing establishments, who consume nearly the entire quantity imported. Some of the better kinds of Brazilian isinglass are manufactured in the same way as Russian, and sold at a cheaper rate. No doubt in some instances, this is mixed with, or sold as, the best, and it has been ascertained that acids and other chemicals have been used to improve the colour of Brazilian isinglass, but the test of good isinglass is in the jelly made therefrom. The jelly made from Russian isinglass dissolves readily, furnishes scarcely any sediment and is remarkably firm, pure, and translucent. On the other hand, Brazilian isinglass makes a far inferior jelly, with these remarkable differences : that whilst Russian isinglass is firm, and free from deposit, Brazilian isinglass leaves a deposit of insoluble matter amounting to twenty or thirty per cent., is less readily dissolved, and the jelly is opalescent, and assumes the appearance of milk. On making blanc-mange with the purest Russian isinglass milk is needed to impart the snow-white colour of that Jelly, but in the case of Brazilian isinglass hot water alone will render it nearly of that colour. It is almost needless to add that the blanc-mange is much inferior in quality, and the large per centage of insoluble matter renders the jelly proportionately weak.

The quality of any isinglass may easily be tested by dissolving a small portion in a glass vessel with about a table spoonful of boiling water. The best Russian isinglass will instantly dissolve and scarcely a particle of sediment remain, the soluble matter in this article being, according to the best authorities, ninety eight grains in every hundred. The same test applied to Brazilian isinglass will extract the gelatine, but the shreds from their fibrous character, do not entirely dissolve; they turn white and retain their form unless disturbed, in which case they break up and form a deposit at the bottom of the vessel. If Russian isinglass be adulterated with Brazilian the admixture may easily be detected by the insoluble shreds or white deposit, which is sure to appear in proportion to the amount of Brazilian isinglass that may be introduced. The smell of the latter also is strong, far from pleasant, and forms a great contrast with the faint, inoffensive, sea-weed like odour of Russian isinglass.

Manufacture of Isinglass.— On the arrival of the isinglass into England, the best kinds are submitted to a course of preparation before they are ready for consumption. The Beluga leaf is closely examined and all discoloured parts cut away, the cuttings and other pieces not deemed good enough for the best, are placed aside as seconds or thirds. These in some cases are used for fining the better description of ales, but more generally for wines, liquors, &c. It is also rolled and cut into shreds for domestic purposes, where colour is not an immediate object. Purse isinglass is mostly sold to the brewers, who consume a vast quantity in the fining of their several beverages. Long and short staple isinglass is extensively demanded by cider makers, confectioners and others, to whom it is sold in the same state as imported into this country. Leaf isinglass taken from the Beluga, after having been picked from all impure or discoloured pieces, constitutes the very best article, either for dietetical use, or for the higher class of clarifying purposes. This description of isinglass has to undergo a process of manufactnre before it is ready for use. What are termed perfect specimen leaves are nearly round, the bladder having been opened longitudinally about two feet in circumference and weigh from eight to sixteen ounces, according to the thickness of the sound. It is not uncommon however to meet with heavier samples, some having been known to reach four pounds. A steam engine of some eight or ten-horse power is generally used under the present method of preparing isinglass, the adjunct machinery consisting of a series of powerful rollers, arranged in pairs in a manner resembling those used for expressing the juice from the sugar cane. The rollers when in motion are fed with leaf isinglass as fast as possible, which, in passing between the two rollers, becomes amalgamated and spread out, and is expelled from the opposite side

of the rollers in one continuous sheet. The isinglass thus rolled is called "ribbon," but it is not yet ready for the process of cutting. The sheet or "ribbon" is probably a sixth, eighth, or tenth part of an inch in thickness, and as it is necessary to reduce it until it is as thin as writing-paper it is passed through rollers more closely set, until, as the thickness diminishes, the desired result is obtained; the width of the "ribbon" of course increasing. It is to be remarked that in rolling the ribbon being confined to the width of the rollers generally about two feet, increases only lengthways and when completed, can be folded or rolled up in the same manner as a length of common linen. After a brief delay for the purpose of drying, the next and last process of cutting is effected. By the introduction of modern machinery, this part of the preparation of isinglass is performed with surprising celerity and the material is cut into very fine shreds. The cutting machine is a cylinder with some five or six keen-edged blades fixed in a tangential direction to the cylinder. The same engine which serves to roll out the isinglass, as already described, suffices to turn this little machine at the rate of some 800 or 1000 revolutions per minute; taking a low estimate we will suppose it turns 800 times. On examining the cylinder we find five or six blades set in it, and as each of these knives severs a shred from the width of the "ribbon" while the cutting process is going on, it follows that four or five thousand shreds are cut in the short space of one minute. Such is the plain and simple method of preparing cut isinglass. There are, however, many consumers who still prefer the old-fashioned style of hand-cut isinglass. In this case the thin leaf is pulled to pieces with the fingers or divided into strips with scissors, a work mostly performed by women. The isinglass is of course in much thicker pieces, but nevertheless it is still preferred by some, not on account of its cheapness as the cost of preparation is much about the same as machine-cut isinglass. We have now given a general discription of isinglass, enumerated the fish from which it is obtained, described the fisheries, the preparation of isinglass, and its manufacture. From a paper by Dr. Pereira, in the fifth volume of the Pharmaceutical Journal, page 66, we learn that theSamovy isinglass referred to is obtained from the silurus glanis, the Russian name for which fish is Som, whence the word Samovy or Somovy is no doubt derived. A difference of opinion has been entertained as to which coat of the air-bladder yields the isinglass. The several layers which enter into the composition of the swimming bladder, commencing from without, are 1st, a peritoneal coat; 2nd, a middle coat composed principally of a modification of what is known as white fibrous tissue; and 3rd, an internal epithelial lining. Blood-vessels rami-

fy through both the external and middle coats, but are most abundant on the inner surface of the latter. These vessels are sometimes described as forming a distinct vascular layer. Some also make mention of a muscular coat entering into the formation of the air-bladders of certain of the fish from which isinglass is obtained and it is probable that more or less muscular fibre of the unstriped kind is present in nearly all cases. Of these coats, the external, or peritoneal covering, is; we believe, usually stripped off; while the internal, which is very thin and forms but little of the substance of the air bladder, is also generally removed in the washing and cleansing to which the isinglass is subject. In the case of purse isinglass it is not removed however. There remains then only the middle coat and it is this we believe which furnishes the isinglass a view entertained by Dr. Pereira, as appears from the second edition of his Materia Medica. The accuracy of this opinion has been however called in question by Dr. Edward Marting, who describes the air-bladder as consisting of only two membranes, an outer strong shining and fibrous membrane and an inner, soft, mucous coat. The inner membrane, namely, the mucous membrane, writes Dr. Marting, is the isinglass. To this description Dr. Marting appends the following note.—"Pereira (Elements of Materia Medica vol. ii. second edition, p. 1861.) erroneously regards the middle coat as yielding gelatine. It appears from the description of Dr. Marting as well as from the above remark that he has overlooked the epithelial lining altogether and has not therefore enumerated this as one of the coats of the air-bladder. The isinglass membrane of Dr. Pereira and the mucous membrane of Dr. Marting, there is therefore reason to believe, are one and the same. The epithelial layer is insoluble in boiling water and in some instances it is so thick, as in purse isinglass, as materially to deteriorate the value of the article. When dry, isinglass is transparent, but when immersed in cold water for a few minutes it becomes white and opaque. Under the microscope it presents a fibrous structure which immediately disappears on the addition of dilute acetic acid, the isinglass swelling up and again becoming very transparent. Examined with the microscope after the action of acetic acid, the walls of the blood-vessels, sometimes the white corpuscles of the blood, and scattered nucleated fibres of fibre-elastic tissue, may be seen. Now in all these particulars isinglass resembles very closely white fibrous tissue a modification of which it is evidently to be considered. The jelly made even from the best Russian isinglass is when cold slightly opalescent. This is due to the presence of a small quantity of albumen. The whiteness of the jelly of Brazilian isinglass, which is so remarkable, results from the presence of a much greater amount of albuminous matter.

Gelatine.—Now as gelatine is obtained from these substances and is extensively employed as a substitute for isinglass, we will, in the next place, proceed to give a description of its preparation. From Pereira's Materia Medica we learn that gelatine is extracted from the bones of the ox and the sheep. It is obtained by boiling bones in water under pressure. It is more readily procured by employing bones which have been previously digested in hydrochloric acid to extract the phosphate of lime. In this way, a nutritious soup is prepared in Paris for the hospitals and other pauper habitations. The patent gelatine of the shops is obtained, I presume, from bones. It is sold either plain or coloured, and is used as a substitute for isinglass. Gelatine has been extracted from antediluvian bones. A soup was prepared from the bones of the great mastodon by a prefect of one of the departments of France. The patentee commences his specification by stating that heretofore, in manufacturing gelatine, it has been usual (with one exception) to act on large pieces of hides or skins, and to employ acids and alkalies, together with mechanical and other processes which occupy considerable time and are likewise costly, and in the excepted case above referred to, it has been the practice to reduce the pieces of hide into the state of pulp in a paper machine, and then to employ blood to purify the product obtained. This invention consists in the following more simple mode of manufacturing gelatine. The patentee takes hides or skins, or parts thereof, as fresh and sweet as possible, and free from hair, and he reduces the whole into shavings or thin slices or films, by any suitable instrument, he soaks the shavings or films for about five or six hours in cold water, and then changes the same; he repeats such changing of the water two or three times each day, until no smell or taste is to be detected, either in the water or in the shavings, and then he removes the shavings from the water. If this product is intended for soup, it is dried on nets, and is then ready for use. If gelatine is to be extracted, the shavings, after the above soaking, are put into a suitable vessel, with a quantity of water, sufficient to cover them when pressed down, and they are subjected to a heat not exceeding boiling water. When dissolved, the gelatine is to be strained through linen or other fabric, subjected to slight pressure with the hands or otherwise, or the solution may be permitted to run off from the vessel without straining, by which means much of the gelatine will be separated from the fibrous matters. The product of gelatine thus obtained is run in thin films on to a smooth surface of slate, or other suitable material, to set; it is then removed on to nets to dry, and when dry it is cut up with an isinglass cutter or other suitable apparatus. The residue, dried or not, may be used for thickening soup, and other culinary purposes." "Another ma-

nufacture of gelatinous substances is produced by the following process, from cod sounds, or other fishy matters capable of yielding gelatine: These matters are reduced to shavings or thin films, soaked in water, subjected to the action of heat, and the gelatine strained or run off as above described. The patentee obtains a first, second, and third product of gelatine, which he forms into sheets, and when dry cuts up the same with an isinglass cutter. This manufacture of gelatine will be found highly useful as a cheap substitute for isinglass for clarifying liquids." Isinglass and gelatine differ very considerably from each other in many of their characters, and especially in the following. The shreds of isinglass, when immersed in cold water, becomes white, opaque, soft, and swollen. The swelling of the shreds is equal in all directions, so that, when viewed with a low power of the microscope, they appear more or less quadrangular. In boiling water, they dissolve nearly without residue. The smell of the dissolved isinglass, when hot, is somewhat fishy, but not unpleasant. The shreds of gelatine, on the contrary, when placed in cold water, swell up, acquire increased transparency, and become transluent and glass-like. The form which the threads take in swelling is peculiar: they do not, like those of isinglass, swell equally, and remain quadrilateral, but become expanded, flat, and ribbon like, the broad surfaces corresponding to the incised margin. The dry threads on the uncut surfaces frequently present a peculiar, shining lustre, not unlike that of tinsel. In boiling water, the shreds do not entirely dissolve, but in most cases a copious deposit falls to the bottom of the glass. The smell of the hot infusion is like that of glue, and therefore disagreeable. It thus appears that between isinglass and gelatine there are several well-marked distinctions some of these sufficiently simple to enable the ordinary observer to distinguish for himself the one from the other. The action of a little cold water on a few of the filaments spread out on glass is all that is necessary for the discrimination. From the above Table, it appears that out of the twenty-eight samples of isinglass submitted to examination, ten, or more than one third, of the samples consisted entirely of gelatine. That the price of the genuine isinglass varied from 8d. to 1s. 4d. per ounce; while that of the gelatine ranged between 10d. and 1s. 4d. per ounce. Now, as isinglass is very different from gelatine in many of its properties, and as it is undoubtedly much the superior of the two, it is evident, from these inquiries, that the public are seriously imposed upon and injured by the substitution for isinglass of such an article as gelatine.—*Food and its Adulteration, p.* 359.

(4560) ISOETES COROMANDELIANA. Lin.

Nechetty kalung, Tam. | Ghee ka gudda, Duk.

This grows in low, moist grounds, and is eaten by the common people.—*Ainslie, p.* 249.

(4561) ISONANDRA, a genus of Plants belonging to the natural order *Sapotaceæ*. It is distinguished by the stamens being all fertile, and twice as numerous as the lobes of the corolla. —*Eng. Cyc.* The *Isonandra Gutta* flourished for centuries in its native jungles, exuding its juice only to be received by the soil, before the discovery was made, only a few years back, that Gutta Percha was suited for such an infinite number of applications; now, there is scarcely any vegetable product more extensively useful, or one more generally sought after for mercantile purposes, a regular supply being of much consequence to some manufactures. To urge the necessity of exercising careful vigilance in protecting the trees whence so valuable a product is derived, will perhaps appear unnecessary, but we know that even their admitted financial value has not been sufficient to protect them from thoughtless and unnecessary waste (but the contrary), as has been illustrated by various writers in the Journal of the Indian Archipelago. The geographical limits of the taban or Gutta Percha tree, have yet to be ascertained, and the properties of the other species of Isonandra, indigenous in our forests, remain to be investigated. Considering the chemical nature of such secretions, we are full of hope that some trees among its numerous congeners, furnishing a similar gum elastic will be brought to light, and the various appearances of the article imported lead to the impression that it is derived from different trees. Dr. Montgomerie, Bengal Establishment, first transmitted specimens of this substance to England, (1st March, 1843), and received the gold medal of the Society of Arts for its introduction, "as a new and hitherto unknown substance, likely to be useful for various purposes in the Arts," and if he had been an exhibitor in the Crystal Palace, we understand that a further award for the discovery would have been made to him.—*Dr. Cleghorn.* Dr. Wight, in Icones,—gives Isonandra Candolleana, 1220; lanceolata, 359; *Percha*, 1589; Perrottetiana, 1219; polyandra, 1589; villosa, 360.

(4562) ISONANDRA GUTTA, (Hooker), the Gutta-Percha Tree, has its leaves on long stalks, obovate-oblong, with a short point golden beneath; flowers axillary, fascicled; stamens 12. This tree is a native of the Malayan Archipelago. The substances yielded by this tree, and designated by the name of Gutta-Percha (pronounced 'Pertsha'), is, like Caoutchouc, a carburet of hydrogen, and isomeric with that substance, and possesses a great number of the properties which characterise India-Rubber but exhibits certain special properties which admit of its being applied to particular uses to which caoutchouc is not adapted. Gutta-Percha possesses as great an indestructibility by means of

chemical agents as caoutchouc. It has an intermediate consistence between that of leather and wood; it is capable of being softened by heat, and of regaining its primitive consistence on cooling. It is therefore at the same time capable of taking and of retaining the most delicate impressions. The important uses to which it has been latterly applied are only the forerunners of those to which it will be adapted hereafter, provided, the lack of this precious material (which unfortunately is produced in much less quantities than India-Rubber, and in localities much more circumscribed) does not present an obstacle to it. But as the plants which furnish caoutchouc abound in the whole of the territorial zone which extends between the tropics, so the *Isonandra gutta* is not the only tree which yields Gutta-Percha. It grows scarcely anywhere except in certain parts of the Malayan Archipelago, and up to the present time has been almost exclusively obtained from Singapore. It was brought for the first time into England in the days of Tradescant, as a curious product, under the name of Mazer-Wood; and subsequently it was frequently brought from China and other parts of the East, under the name of India-Rubber, in the form of elastic whips, sticks, &c. In 1843 Doctors D'Almeida and W. Montgomery drew particular attention to it, together with its various singular properties, its easy manipulation, and the uses for which the Malays employed it. The most common employment of it was for whips; and it was by the introduction of a horse-whip made of this substance that its existence was for the first time known in Europe. The specimens of the products of the East Indies, shown in the Great Exhibition of 1851, proved that the natives of the country in which the *I. Gutta* grows know also how to appropriate it to the manufacture of different kinds of vases, and that European industry has little more to do than to imitate their processes. The importation of Gutta-Percha into England, where the employment of this substance first drew attention, was in 1845 only 20,600 lbs.; but in 1848 it had increased to above 3,000,000 lbs.; and during the last five years the importation has amounted to a much larger quantity, and one which begins to cause some apprehension as to the possibility of the supply sufficing for the requirements of the novel uses in store for it in the future. It is true that during its use Gutta-Percha is but little consumed, and the waste from the articles in this material, submitted to a proper softening, can be made to serve new uses; nevertheless its constantly increasing consumption, added to the barbarous manner in which the product has hitherto been extracted, may well justify some apprehension. During the first few years of the employment of Gutta-Percha it was the custom to cut down the tree for the purpose of obtaining the juice, which, left to itself, very soon allowed the Gutta-Percha to separate and coagulate of its own accord. There is reason to hope that European industry will soon be embarked in the cultivation of this product, and that the Niato (which is the name that the Malays give to the tree which produces Gutta-Percha), multiplied by means of a regular culture, naturalised in other countries than those to which it is indigenous, and worked by regular incision, which will only take from the tree a portion of its juice without hindering its development, will be the means of furnishing at a low price a substance which is destined to render notable services to industrial and domestic economy. The Gutta-Percha which arrives in Europe in the form of lumps of some pounds weight is far from being pure. The natives of the Malayan Archipelago make no scruple of introducing into it stones, earth, &c.; the presence of which in the interior of these blocks renders a purification indispensable, which purification however is capable of being attained without much manipulation. Indestructible by water, and at the same time a bad conductor of electricity, Gutta-Percha has been found available for inclosing the metallic wires employed in the electric telegraph; and the use of this substance may certainly claim its share in the success of the submarine telegraph, by means of which London and Paris and the other great cities of Europe are now brought within a few minutes of each other. It may be conceived to what a variety of forms a substance can be turned which, becoming soft, without adhering, at the temperature of boiling water, regains at the ordinary temperature the slight elasticity and the consistence of leather.—*Eng. Cyc.*

(4563) ISORA CORYLIFOLIA. Some good white fibres from the bark of the *Isora Corylifolia* were exhibited by the Madura Local Committee, by Mr. Saldanah and Mr. Jaffrey. The same fibre is called Googull and is made into excellent Ropes at the Training Depot.—*M. E.*

(4564) ISOTOMA AXILLARIS. This is a beautiful elegant plant, the flowers of which, look like a large lilac jassamine, and are cultivated like the Lobelia.—*Riddell.*

(4565) ISPAGULA. ISPAGOOL. Seeds of Plantago Ispagula.

(4566) ISREE. At the Madras Exhibition of 1855, Conjetty Arjapah Chetty exhibited excellent unbleached Isree to which a prize of 50 Rupees was awarded. Vizagapatam Isree: Nellore white Percalah, and Jyempettah Soocey, were all specimens of accurate workmanship, evincing much pains and skill. It is a cotton cloth.—*M. E. of* 1855.

(4567) IURINEA. COMPOSITÆ. All the species succeed well in any common soil, the colour of the flowers are purple, red and yellow, and may be cultivated from seed, or by dividing the roots.—*Riddell.*

(4568) IVORY. A beautiful and compact substance, obtained from the tusks of the elephant, the narwhal, the walrus, and the hippopotamus, and also from the teeth of the same animals. The best and largest supply is however from the elephant. The male elephant when full grown has two tusks, varying considerably in size on different animals, but most valued when they are large, straight, and light in colour. These tusks are hollow at their insertion into the jaw, and for a considerable space therefrom, but become solid as they taper towards the extremity. The principal sources whence they are obtained are the western coast of Africa and Hindostan; but the African tusks are most esteemed, as being denser in texture, and less liable to turn yellow. By an analysis, the African show a proportion of animal to earthy matter, of 101 parts to 100; while in the Indian it is 76 to 100. The applications of ivory are so numerous that a large demand for elephants' tusks has existed for a lengthened period. During twelve years at the close of the last century, the imports into Great Britain amounted on an average to 1,576 cwts. annually; in 1831 and 1832 they had increased to 4,130 cwts., of which 3,950 cwts. were retained for home consumption. Now, reckoning the medium weight of a tusk at about sixty pounds, it is evident that the imports of the years last named would require 7,709 tusks, or the destruction of 3,854 male elephants. But since that period the imports have so greatly risen, that in Sheffield alone 180 tons of ivory are worked up annually into knife-handles, &c. It is also affirmed that of the quantity of tusks imported, although some weigh from 60 to 100 pounds, yet the number of small tusks is so enormous, that an average weight of nine pounds can only now be reckoned on; in which case 45,000 tusks, from 22,000 elephants are required to supply the demand of this great cutlery mart of England. Occasionally, it is allowed, broken or shed tusks are collected, or those of animals which die a natural death are obtained; but the supply from these sources is never very large, so that the slaughter of elephants, after all deductions made, is going on at a rate which leaves it a constant wonder that the breed of this noble animal has not been sensibly diminished. The value of the ivory consumed in Sheffield is very great; but there are also other seats of manufacture, and ivory is wrought into the forms of chess-men, billiard-balls, the keys of musical instruments, thin plates for miniatures, mathematical and other instruments, and an immense variety of small objects of use, amusement, or ornament. None of our manufactures have yet reached the consummate skill of the Chinese in the workmanship of ivory, chiefly remarkable in their concentric balls, their chess pieces and models. Yet the adaptation to useful purposes of this valuable substance is fully understood by those who cannot rival the exquisite minuteness of Chinese art. A manufacturer of surgical instruments in Paris is in the habit of rendering ivory flexible for use as tubes, probes, &c., by acting on the well-known fact, that when bone are subjected to the action of hydrochloric acid the phosphate of lime, which forms one of the component parts, is extracted, and thus bone retain their original form, and acquire great flexibility. M. Charriere, after giving the pieces of ivory their required form and polish, steeps them in acid, either pure or diluted, until they become supple and elastic, and of a slightly yellow colour. In the course of drying the ivory returns to its original hardness, but its flexibility can be easily restored by surrounding it with wet linen, or by placing wet sponges in the cavities of the pieces. In some cases, the articles have been kept in the acidulated water, in a flexible state, for a week, without change or injury, and without acquiring any taste or disagreeable smell. It has lately been ascertained that the decay of articles in ivory can be effectually checked, even when its progress has advanced so far as to cause the specimens to crumble away under the hands. Some of the works in ivory forwarded by Mr Layard from Nineveh, were found on their arrival in England to be in a state of rapid decomposition. Professor Owen was consulted on the subject, and he suggested a remedy which has proved entirely successful, thereby preserving to this country these curious relics of ancient art. Concluding that the decay was owing to the loss of gelatine in the ivory, he recommended that the articles should be boiled in a solution of gelatine. Under this process they became apparently as firm and solid as when they were originally entombed. The tusks of the hippopotamus afford a very hard and white ivory. These are usually short and much curved, hollow at the place of insertion, and covered with a glossy enamel. They vary in weight from three or four pounds to thirty. These are highly prized by the dentists, and are better adapted than any other ivory for making artificial teeth. The thick coat of enamel which covers them has first to be removed, for this entirely resists steel tools, and under it is found a pure white ivory with a slight bluish cast. The parts rejected by the dentists are used for small carved and turned works. The horn or tooth of the narwhal is also hard and susceptible of a fine polish. The largest size is ten feet long; at the lower extremity it forms a slender cone of a twisted or spiral figure. Another and a very remarkable source of ivory is that which supplies almost the whole of the ivory-turner's work made in Russia. Along the banks of the larger rivers of the Russian Empire, and more particularly those of further Siberia, thousands of tusks are annually dug up, which once constituted the weapons of defence of a species of elephant or mammoth now ex-

tinct. These form what is called *fossil ivory*, but they have not undergone the changes usually understood in connexion with the term fossil, for their substance is as well adapted for use as the ivory procured from living species. So numerous are these tusks, that they are occasionally exported from Russia, being cheaper than recent ivory. They are rarely to be met with in England, except in museums. Mention is made, however, of one which measured 10 feet in length, and was solid to within 6 inches of the root, weighing no less than 186 lbs.: this was cut up into keys for piano-fortes. There is a substitute for ivory now in general use, which it is necessary to notice here. It is the fruit of a species of palm, imported from Peru for some time past into the European market, and named by two Spanish botanists, who met with it in the groves of Peru, *Phytelephas macrocarpa*. These writers also supply the following description :—"The Indians employ the leaves of this most beautiful palm as a covering to their cottages. The fruit at first contains a clear insipid fluid, with which travellers quench their thirst; this fluid afterwards becomes gradually sweet and milky, and at length acquires solidity, so as to be as hard as ivory. If the fruit be gathered while the juice is fluid, the latter soon becomes acid; but when allowed to attain perfection, the kernels are of sufficient hardness to be employed by the Indians as knobs for walking-sticks, reels of spindles, and little toys, which are white, and perfectly hard while dry; if they are put under water they soften, but on drying, their hardness is restored. Bears eagerly devour the young fruit." Two species of this palm are recognized, the *P. macrocarpa*, or large-fruited, and *P. microcarpa*, or small-fruited. The vegetable ivory is in fact the albumen or nutritious substance surrounding the embryo, and which in some other palms, as the cocoa-nut palm, constitutes a beautiful and firm substance lining the shell. The vegetable ivory is enclosed in a hard rind, some of which generally adheres to it as imported. The Doum Palm has a similar albumen, which is turned into beads for rosaries. The African ivory, as already stated, is superior to any other: its appearance, when first cut, is mellow, warm, and transparent, almost as if soaked in oil, and with very little appearance of grain or fibre; the oil dries considerably by exposure, and a permanent tint then remains, a few shades darker than writing paper. The Asiatic ivory is more dead-white at first, but is more disposed of the two to turn yellow afterwards. It is also less dense, and does not take so high a polish. The choice of ivory is accompanied with much uncertainty, even to experienced buyers. The tusks are received in all varieties of size and figure. They may be 8 or 10 feet long, or only as many inches. They may weigh (as we learn from the magnificent specimens in the Great Exhibition) 325 lbs. the pair, or they may not reach as many ounces. Mr. Holtzapffel mentions a small and hollow tusk in his possession, which only weighs 2½ ounces. Their curvature may describe a simple half circle, or they may be curved in two directions, the tusk inclining to the shape of the letter S. The outside may be dark-coloured almost to blackness, or it may be run through all the varieties of light and deep orange, hazel, and brown; their ends may taper off to a fine point, or they may be very much worn away, or they may end abruptly as if broken off. The buyer, therefore, has to make the best selection he can by choosing a tusk as nearly straight, solid, and round as possible, with a smooth rind free from cracks, and a point that gives evidence in the worn part, that the tusk is of the desired fineness of grain. Yet after all precautions, it is only after the first cut of the saw that the quality can be really determined. Sometimes the interior exhibits a succession of layers or rings, of different shades and degrees of transparency; sometimes the solid parts of the most beautiful and transparent tusks have long oval patches of opaque white ivory, in some cases a regular grain is observable, almost like the engine-turning of a watchcase; in others no grain is perceptible; occasionally there is a deficiency of animal oil, and the ivory crumbles under the workman's tool; or there may be the serious defects of darkness of colour, and coarseness of grain. In rare instances a considerable portion of the tusk is found to have been injured by a musket ball, the iron or leaden bullet being enclosed in it. Two instances, if not more, have occurred in which these bullets were of gold, showing that the shot was fired by royal hands, for it is the reputed custom among Eastern potentates to use gold or silver bullets in their sports. One of these golden bullets is stated to have been cut through by a comb-maker in dividing a tusk. The portion of the tusk thus injured, is generally useless for any ornamental purpose for many inches each way around the ball; but cases have occurred in which a ball, and even a spear-head, has entered at the thin part near the skull of the animal, and become embedded without injury to the external surface. Great economy is used in cutting up the tusks, so that the only waste may be that which arises from the passage of a thin saw between the several pieces into which it is divided; and even here it can hardly be termed waste, for the clean saw-dust of the ivory is sometimes used in making jelly. Every portion is, in fact, turned to some account, the outside rind being used for handles of pen-knives, &c., and the scraps burned in retorts for the manufacture of ivory black, used in copper-plate printers' ink, and for other purposes. The saw used in cutting up the ivory is about the fortieth of an inch thick, with rather coarse teeth, about five

or six to the inch: it is stretched in a steel frame to keep it very tense. The sawing is commenced at the root end, and two or three pieces are cut to the length of such articles as can be made in that thinner portion of the tusk. The blocks are rarely cut more than five or six inches long. As the solid part of the tusk is reached, the blocks have to be greatly subdivided; perhaps longitudinal slices have to be cut for miniatures, or the taper handles of knives and razors have to be economically severed by cutting the slabs wedge form, the thick end of one against the thin end of the next, and then subdividing by parallel or inclined cuts, made either with the saw just described, or with the circular saw. The entire division of each block or length of tusk is settled and accurately marked in pencil upon the end of the piece, before the saw is used. When the tusk is to be used for turnery work only, the first cut is usually made where the hollow ends, which is ascertained by thrusting a wire up the tusk. Unless the latter is extremely curved, the principal pair is formed into cylinders or rings, but the greater the curve the shorter the pieces that can be prepared from it without waste.

(4569) IVORY BLACK. A kind of animal charcoal, procured by the incineration or close distillation of ivory, and of the horns or bones of animals. It is extensively used in the arts.—*Waterton.*

(4570) IVORY (ELEPHANT,) of Elephants Teeth.

Ivorie. Fr.	Huthee Danth, Guz. Hind.
Elfenbein, Ger.	Duudhan-i-feil, Pers.

The teeth or tusks of the Elephant. They are largely imported into Bombay from the African Coast, Zanzibar, &c. and are chiefly re-exported to England.

(4571) IVORY (FOSSIL), Are the tusks or teeth of the Mammoth, which are found plentifully, and in a high state of presservation in the Laichovian isles, and on the shores of the Frozen Sea. They are chiefly used by the Russian turners.

(4572) IVORY-NUTS, OR COROSOS, are produced by Phytelephas macrocarpa, growing in central America and Columbia, (Humboldt.) They are described as seeds with osseous albumen; the tree is a genus allied to the Pandaneæ, or screw Pines, and also to the Palms. The nuts are of irregular shapes, from one to two inches diameter, and when enclosed in their thin husks, they resemble small potatoes covered with light brown earth: the coat of the nut itself is of a darker brown, with a few loose filaments folded upon it. The internal substance of the ivory-nut resembles white wax rather than ivory; it has, when dried, a faint and somewhat transparent tint between yellow and blue, but when opened it is often almost grey from the quantity of moisture it contains, and in losing which it contracts considerably. Each nut has a hole, which leads into a small, central, angular cavity; this, joined to the irregularity of the external form, limits the purposes to which they are applied, principally the knobs of walking sticks, and a few other small works.—*Holtzapfel.*

(4573) IVORY, (WALRUS OR SEA HORSE), Moye-Danth, Guz. Hind.

The tusks or teeth of the Sea-horse or Walrus, and Hippopotamus, are also used as ivory. They have a curved form and grooved surface, are much harder and whiter than those of the Elephant, and do not turn yellow so soon. They are now chiefly used in dentistry. They are imported into Bombay from the African coast, Zanzibar, &c., and are almost entirely re-exported to England.—*Faulkner.*

(4574) IVORY-WARE. The elegant carving of the Chinese in ivory, and the cheapness of the articles, causes a large sale of the most useful to all parts of the world. Fans, seals, paper-knives, chessmen, &c. &c., are exported principally to the United States and India, but also to South America, Europe, &c. Under the old system, 100 ivory fans were estimated to weigh 6 catties, 4 taels, and paid 6¼ mace duty. The Chinese manufactures in ivory, greatly surpass in delicacy and elegance the works of European artists. The most elegant are, *Camp Baskets*, consisting of several pieces placed upon each other, surmounted with a handle, richly carved: —*Work Baskets* of various shapes:—*Fans*, some in open work: others with figures and ornaments raised, or in relief:—*Hand Screens* wrought in a similar manner:—*Card Racks*, &c. But the most singular article is the *Wrought Ball*, which contains from nine to fifteen internal globes, one within another, wrought from a solid piece of Ivory, through apertures not more than half an inch in diameter.—*Comp. Desc.* Fine ivory carved work can be executed in Shorapore, in the Dekhan, of a peculiar and very delicate description. This consists of figures of deer and birds, flowers, as also combs large and small, cups, &c. &c. Any orders for which would be executed with peculiar care. It would be impossible to define the prices of these articles, as they would depend upon the size and work required.—*M. C. C.* At the Madras Exhibition of 1855, a very interesting and complete series of carvings in Ivory was exhibited by His Highness the Rajah of Travancore. It comprises many of the common animals, reptiles, fruits and flowers of the country, which are carved with taste and carefully finished. There was a good deal of grace and spirit in the action of the animals, some of which were in natural attitudes particularly a bull and cow, two deers, a cheeta and a rabbit. Of the reptiles, a frog and lizard were well represented, and a pair of paper cutters with ornamental handles were particularly deserving of notice, one for the judicious adaptation of a com-

mon garden flower to the design, and the other of a lizard in a spirited attitude. The fruits and flowers were well represented and the whole series evinced a perception of the natural beauties of the objects represented. The Jury recommend a 2nd Class Medal for the series. Ivory of Madras Exported is lbs. 4,810, Rs.71507. Several specimens of fine Ivory were exhibited; the largest pair of Elephant tusks sent to the Exhibition, weighed 180 pounds, obtained from a wild Elephant killed in the Travancore forests. One tusk weighed 71 pounds, the other 67 pounds, and showed a fine white compact kind of ivory; of these two, one measured 6 feet 8 inches in length, and the other 6 feet 6 inches, the circumference at the base being 17 inches in each case. The domestication of the Elephant is usually attended by deterioration of the length and quantity of the Ivory.—*M. E. J. R.*

(4575) IXIA CHINENSIS AND CAPENSIS. *Iridaceæ.*—These beautiful flowers vary in colour, and form, they are mostly from the Cape of Good Hope, and require the same cultivation as plants of the Lily tribe, and are propagated by dividing the bulbs.—*Riddell.*

(4576) IXORA, a genus of Plants belonging to the tribe *Cinchonaceæ* and the genus *Rubiaceæ* so named, it is supposed, from the Indian god Iswara. The genus is characterised by having a small 4-toothed calyx; corolla 1-petaled, funnel-shaped; tube long, with the four stamens in its mouth: ovary 2-celled, 1-seeded; style single; berry drupaceous, inferior, 2-seeded. The species are numerous, and chiefly confined to India and the Oriental Archipelago. They form shrubs or small trees, with opposite leaves, and stipules arising from a broad base, but acute at the apex. The flowers are in terminal corymbs, and are usually red, but sometimes white, and are generally highly ornamental, whence several are cultivated in our hot-houses, where they require to be kept in a moist heat to thrive well. Some of the species are used medicinally, but not to any extent. Dr. Horsfield mentions *I. coccinea* as employed in Java as a stimulant, and Rheede two or three other species; but none appear to be possessed of any very active properties.—*Eng. Cyc.* Dr. Wight in Icones gives Ixora acuminata, 706; alba, 707; bndhuca, 149; barbata, 185; brachiata, 710; coccinea, 153,707; cuneifolia, 709; fulgens, 151; lanceolaria, 827; nigricans, 318; Favetta, 1-8; parviflora, 707, 711; polyantha, 1066; stricta, 184, 707; tomentosa, 186; undulata, 708; villosa, 150.

(4577) IXORA ALBA. WHITE IXORA. A white-flowered ixora is a Tenasserim wild flower that ought to be brought into cultivation.—*Mason.*

(4578) IXORA BANDHUCA. JUNGLE GERANIUM.

Bandhooka, Ruktuka, Buckolee, HIND.

A spreading shrub, smaller than I. Coccinea, but equally common: in flower almost during the whole year—of a pale crimson colour; there is also a white variety:—blossoms during the rains.—*Riddell. Irvine.* In the Kotah gardens and jungles, it is a beautiful bush, covered with numerous scarlet flowers all the year and would be very ornamental in gardens.—*Gen. Med. Top. p.* 179.

(4579) IXORA COCCINEA. Crimson Ixora. This species of ixora is very common in front plots, and is sometimes called by the European residents of Tenasserim "the country geranium." Ixora coccinea and other species of that genus, are among the most common shrubs in Chinese gardens.—*Fortune.*

(4580) IXORA PALLENS? Wild Ixora. An indigenous species of ixora is frequently met with in Tenasserim in mountains and plains whose flowers are of a much paler hue than the preceding species.—*Mason.*

(4581) IXORA PARVIFLORA, TORCH WOOD. Small flowered Ixora (at Kotah).

Soowndee cuttay also Karang cuttay, TAM. Henna Gorivi, CAN. | Gandhul, Runghun, Jilpai, HIND.

This is a small tree, employed by the poor for beams and posts. It burns very readily and clearly, and, on that account, the branches of it are often made into torches by people travelling in the night. The Tennam eerk is used in preparing torches in Ceylon; the spathe and receptacle of certain plants are also employed for similar purposes.—*Ains. Mat. Med. page* 203. On the banks and near talaos at Kotah, the flowers of this Ixora are very sweetly scented and the tree blossoms in the hot weather; it would form a very fit ornament for gardens and pleasure grounds.—*Genl. Med. Top. p.* 179.

J.

(4582) JACANA. The singular jacana is a native of China and is distinguished not less by the grace of its form than its adaptation to the localities for which nature has allotted it. Formed for traversing the morass and lotus covered surface of the water it supports itself upon the floating weeds and leaves by the extraordinary span of the toes aided by the unusual lightness of its body. Like the moor-hen, of whose habits and manners it largely partakes, it is doubtless capable of

swimming, the long and pendent tail feathers being elevated so as not to dip in the water.—*Williams' Middle Kingdom, p. 268.*

(4583) JACK TREE. Artocarpus integrifolia.

(4584) JACKWOOD.

Phunsee also Funsee, Guz. Hind.

Jackwood is imported into Bombay from the Malabar Coast, and was at one time in great request for making furniture. Of late years, however, it has been entirely superseded by blackwood for this purpose.—*Faulkner.* Jack is the wood of *Artocarpus integrifolia*, or the entire leaf bread-fruit tree, a native of India, is imported into Britain in logs from 3 to 5 feet diameter, and also in planks; the grain is coarse and crooked, and often contains sand. The wood is yellow when first cut, but changes to a dull red or mahogany colour. It is very much used in India for almost every purpose of house carpentry and furniture, and in England for cabinet work, marquetry, and turning, and also for brushbacks. The Jack-wood is very abundant, and its fruit is commonly eaten by the natives, and rarely by Europeans at desert, with salt and water like olives. The Jackwood is sometimes misnamed orange-wood from its colour and also Jack-wood, Jaack-wood and Kuthul. See *Baker's Papers.* —*Holtzapffell.*

(4585) JADE.

Yu, Chin.

This mineral, referred by Jameson to *Prehnite*, is greatly valued in China. Its colour is greenish-white, passing into grayish-green, and dark grass-green; it is semi-transparent, and cloudy; fracture splintery, and splinters white. It is peculiarly difficult to cut; yet the Chinese take pride in fashioning it into various shapes, such as cups, saucers, bracelets, clasps, and even animals. Some of these articles require the labour of eight or ten years. *Waterston.—Faulkner.* The term Jade, has been given to several Minerals which resemble each other but little, except in colour, and therefore it is one which it would be well should fall into disuse. *Serpentine, Nephrite*, and *Saussurite* have all been described under the name of *Jade.—Eng. Cyc.* The Chinese estimate their celebrated Jade stone very highly, and there are numerous shops, both for cutting it and exposing it for sale, carved into all those curious and fantastic forms, for executing which this people are so well known.—*Fortune's Wandering, p.* 88. Its value in the eyes of the Chinese depends chiefly upon its sonorousness and color. The most valued specimens are brought from Yannan and Khoten; a greenish white colour is the most highly prized, but a plain color of any shade is not much esteemed. A cargo of this mineral was imported into Canton from New Holland not long ago, but the Chinese would not purchase it, owing to a fancy taken against its origin and color. The patient toil of the workers in this hard and lustreless mineral is only equalled by the prodigious admiration it is held in and both fairly exhibit the singular taste and skill of the Chinese. Its colour is usually a greenish white, passing into a greyish-green and dark grass-green internally it is scarcely glimmering. Its fracture is splintery, splinters white, mass simi-transparent and cloudy; it scratches glass strongly but rock-crystal does not scratch it.—*Williams' Mid. King. page* 243.

(4586) JAGREE, Coarse Sugar.

Kund, Arab.	Nulla Vellum, Tam.
Jagree, Goor, Guz. Hind.	Bellum, Tel.
Guda, Gura, Sans.	

A coarse kind of sugar formed by evaporating the juice of sugar canes, &c, in India. Jagree is largely manufactured in various parts of Southern Asia, and is in great request among the lower orders of the natives. A large quantity of Jagree has lately been exported from Bombay to England under the designation of "Coompta" sugar, the place of its produce. It is also exported to the Arabian and Persian Gulfs.—*Faulkner.*

(4587) JAIPHUL, Nutmegs.

(4588) JAIPHUL KA TEIL, Nutmeg Oil.

(4589) JAIWANTRY, Mace.

(4590) JAIWANTRY KA TEIL, Mace Oil.

(4591) JALAP.

Jalap, Fr.	Sciarappa, It.
Jalapp, Ger.	Jalappa, Sp.

The root of a Convolvulus indigenous to South America and Mexico. The root is met with in thin transverse slices, solid, hard, weighty, of a blackish colour on the outside, and internally of a dark grey, with black circular striæ. The odour of jalap, especially in powder, is very characteristic. See *Lewis's Materia Medica.*—*Faulkner.*

(4592) JAMA MUSJID OF DELHI. The Jama Musjid is the principal mosque of Delhi and according to Hamilton's Gazetteer cost ten lakhs of rupees and took six years in its construction. It was begun and completed in the reign of Shah Jehan, and is an edifice worthy of his name. Three of the highest, the broadest and finest flights of steps in Delhi, made of stone, lead to the front and side entrances, whence the spectator comes to a square platform. In the centre of this is a large cistern which is intended for the performance of the "woozoo," or ablutions before prayer. While the three sides open inwardly with a corridor and cloisters, the west of the square platform is the cathedral itself, rising in three large domes and two of the most stately minarets within the town of Delhi. Its space admits of a vast congregation, and on the anniversary of a saint of any celebrity or on any

other particular occasion, it was crowded with the Mahomedans of the place, who always seemed very strict in their devotions.—*Tour in India by French, p.* 10.

(4593) JAMBEE, a cane with stiff stems and large knots, imported from China.

(4594) JAMBOSA ALBA, aquea, *vulgaris*.

(4595) JAMOON, Eugenia Jambolana.

(4596) JANIPHA, a genus of Plants belonging to the natural order *Euphorbiaceæ*. It has monœcious flowere; calyx campanulate, 5-parted petals wanting; stamens 10 in the male flowers, filaments unequal, distinct, arranged round a disc. In the female flowers the style is one; stigmas 3, consolidated into a rugose mass: capsule 3-coccous.

(4597) JANIPHA MANIHOT. Lin. The Tapioca, or Cassava or Cassada root.

Mara Vullie kalung, TAM.	Aal vullie kalung, TAM.
Shuftuloo, DUK.	—*Faulkner*.
Maracheenee, CAN.	

Janipha Manihot (*Jatropha Manihot* of Linnœus) is a native of Brazil but largely grown in India. It has an oblong tuberous root, as big as a child's head, full of a wheyish venomous juice. The stems are white, brittle, having a very large pith, and several knobs sticking out on every side like warts, being the remains of the foot-stalks of the leaves, which have dropped off, usually 6 to 7 feet high, with a smooth white bark; branches crooked, and have on every side near their tops leaves irregularly placed on long terete petioles, broadly-cordate in their outline, divided nearly to their base into 5 spreading lanceolate entire segments, alternate at both extremities, dark-green above, pale-glaucous beneath; the midrib strong, prominent below, and there yellowish-red: from it there branch off several oblique veins, connected by lesser transverse ones; stipules small, lanceolate, acuminate, caducous; panicles, or compound racemes, axillary and terminal, 4 to 5 inches long, bearing sometimes all male or female flowers, at other times these are mixed on the same peduncle; pedicels with small subulate bracts at their base. Male flowers smaller than the female. Calyx purplish on the outside, fulvous-brown within, cut about half-way down into five spreading segments: disc orange-coloured, fleshy, annular, 10-rayed; stamens 10, alternate with the lobes of the disc; filaments shorter than the calyx, white, filiform, free; anthers linear, oblong, yellow. Female flowers of the same colour as the male, deeply 5-parted; the segments lanceolate, ovate, spreading; disc an annular orange-coloured ring, in which the purple ovate furrowed ovary is imbedded; style short; stigmas 3, reflexed, furrowed and plaited, white; capsule ovate, 3-cornered, 3-coccous; seeds elliptical, black, shining, with a thick fleshy funiculus. The expressed juice is dangerously poisonous. Fecula of the root harmless when separated from the juice and exposed to heat. It is called Cassava—a principal article of diet in South America. The nutritious substance known as Tapioca is the Cassava differently prepared and granulated. These preparations are obtained by crushing the roots after the bark has been removed, and straining off the water, when the mass is gradually dried in pans over the fire. (Lindley, *Flora Medica.*)—*Eng. Cyc.* The root is in great estimation amongst the Natives in the Southern parts of the Indian Peninsula, who make it into curry, &c. Previous to its being roasted or otherwise dressed it ought to be well boiled.—*Ainslie, p.* 249. In Travancore Tapioca is extensively cultivated in gardens. Great care is requisite in the preparation of these roots, as they contain a poisonous principle, which is only got rid off by the application of strong heat. The poorer classes use the tapioca flour, but none is exported.—*M. E. J. R.* Tapioca and Moussache or cassava, are the fecula of the root of the Janipha manihot. The juice of the root deposits a white fecula, which, after being well washed and dried, constitutes what is called "*moussache.*" This is formed of rounded grains having a central dark point, and of remarkably equal size, the density of moussache to arrow root is as 14 to 16. When the moussache is dried on hot plates the grains partly burst, and the fecula agglomerates in irregular semi-opaque gumlike masses, and is then called Tapioca. Both these substances constitute excellent articles of diet, especially for convalescents. The Messrs. Speed cultivate the Janipha in the vicinity of Calcusta, and produce a *tapioca* of admirable quality. To prepare *Tapioca* take one ounce of the grains, steep in soft water for an hour. Pour off the superfluous water, and boil with a pound of water for an hour. A transparent uniform syrup-like fluid is obtained, which jellies on cooling, and has a peculiarly rich and agreeable flavour. The juice of the Janipha root from which the fecula has separated is a very formidable poison. *Cassava bread* is made of the tapicoa root, from which the acrid juice and fecula have been removed by washing.—*O'Shaugh., p.* 559. Mr. Mason is not aware that either tapioca, or cassava is manufactured on the Tenasserim Coast, but manihot, the plant which produces both, is frequently seen in culture. The natives boil the root, and eat it like a yam, though severe sickness is often induced by the use of it. The Karen name signifies "tree yam," and in Burmese it is called the "Penang yam," which shows whence it was imported. Malays have told him that much of the sago, and arrow root which comes from Penang and Singapore, is made from this plant, though the former is usually supposed to be prepared from the sago

palm; and Mr. Ranney informs him that arrow root is made from it at the Mauritius. It is said that an acre of ground, planted with the cassava tree, yields nourishment to more persons than six acres cultivated with wheat. It is of easy culture. Though Cassava, or Manioc, is obtained from the roots, these abound in a highly poisonous juice, which contains Hydrocyanic or Prussic Acid, so that very small doses produce the most dangerous consequences. The acid however is easily driven off by heat, and consequently there is no practical difficulty in procuring the nutritious substance in a pure state. In order to effect this the roots are peeled, well washed, and then ground between millstones till they are reduced to the state of paste. This is subjected to pressure for the purpose of depriving it as far as possible of the juice: the residue is placed in vessels over a brisk and regular fire, and continually stirred until it becomes dry; it then acquires a granular appearance, is gradually cooled, and afterwards packed in barrels, when it may be preserved for a great length of time. Half a pound of this substance daily is said to be sufficient to support a vigorous man. Tapioca is a preparation of Cassava, but contains less nutritive matter. Topioca consists almost entirely of starch.—*Eng. Cyc. p.* 793.

(4598) JANAPUM. Thin rope made of the fibre of Crotolarea juncea.

(4599) JAPANNED WARE. LACKERED WARE.

Marchandises de Japan. FR. | Japansch lakwerk DUT. Japanischie ware, GER.

Articles of every description, such as tea-trays, clock-dials, candlesticks, snuff-boxes, &c. that are covered with coats of Japan, whether plain or embellished, with painting or gilding. Birmingham is the grand mart of this manufacture, which is there carried on to a great extent.—*McCulloch. Faulkner.*

(4600) JASMINACEÆ, *Jasminworts*, a natural order of Monopetalous Exogens, deriving its name from the *Jasminum*, which forms one of its genera. It is one of the very few orders of that class with regular diandrous flowers, and is only to be mistaken for *Oleaceæ*, which have a valvate corolla, and which otherwise are scarcely different. Only five genera of this order have yet been discovered, the principal being *Jasminum* itself, which consists of a large number of species, sometimes fragrant, sometimes scentless, erect or twining, inhabiting the hot or temperate regions of Europe, Africa, and Asia, including Australia, but hardly known in America. The order is characterised by having opposite or alternate simple or compound exstipulate leaves. Monopetalous flowers, the segments of whose corolla are imbricated, and seldom correspond with those of the calyx; two stamens, and a superior 2-celled few seeded ovary. The species, about 100 in number, are chiefly valued for their fragrance; a few species have been regarded as bitter and astringent.—*Eng. Cyc. Vol.* III. *p.* 302.

(4601) JASMINUM. A genus of plants belonging to the natural order *Jasminaceæ*. It has a tubular 5 or 8 cleft calyx; a 5 or 8 parted corolla; stigma 2-lobed or bifid; berry didymous, having one of the lobes usually abortive; seeds without albumen. The species are usually twining shrubs, leaves simple or compound; petioles articulated; flower white or yellow.—*Eng. Cyc. Vol.* III, *page* 301. Many of the Jasmines are very pretty shrubs with white and yellow flowers, in most cases scented. The yellow varieties should be grown in pods, but being natives of the higher latitudes of the tropics, they often perish during the hot season, they require a loamy soil well manured, and perfect drainage. The white varieties grow well in the flower borders, requiring to be pruned occasionally, to keep them in proper form, this should be done after flowering.—*Riddell.* The species given in Icones, by Dr. Wight, are affine, 1255; angustifolium, 698, 700; arborescens, 699, 703; *aureum*, 1258; auriculatum, 700, 1254-55; *bignoniaceum*, 1858; bracteatum, 1248; brevilobum, 1254-55; chrysanthemum, 1258; Courtallense, 1252; elongatum, 702-701; erectiflorum, 1251; flexile, 1252-53; grandiflorum, 1257; hirsutum, 702; latifolium, 699, 703; *laurifolium*, 1247; Malabaricum, 1250; *myrtifolium*, 1247; ovalifolium, 1256; *pubescens*, 702; revolutum, 1258; rigidum. 1247; Rottlerianum, 1249; Sambac, 704; simplicifolium, 705; *tetraphis*, 1247.

(4602) JASMINUM ARBORESCENS. TREE LIKE JASMINE.

Munem-manus, HIND.

A beautiful large fragrant flowered species, cultivated at Ajmeer.—*Genl. Med. Top. p.* 172.

(4603) JASMINUM ANGUSTIFOLIUM. ROOT OF THE NARROW LEAVED JASMINE, Lin.

Caat mallika vayr. TAM. Adivie mallevayroo, TEL. | Kanana mullika, SANS.

J. angustifolium, Narrow-Leaved Jasmine, is a native of the Coromandel coast. It is a twining bright plant, with ovate or oblong leaves, smooth, of a shining deep-green colour. The flowers are large, white, with a faint tinge of red, star-shaped, having a peculiar but very pleasing fragrance. The bitter root of this species, ground small and mixed with powder of *Acorus calamus* root, is considered in India as a valuable external application in cases of ringworm. The plant being constantly covered with leaves of a bright deep-green, sometimes as small as those of Box, render it always beautiful and well adapted for screening windows and covering arbours in warm climates.—*Eng. Cyc.* Another Sanscrit name of the plant is Asphota.—*Ains. Mat. Med. p.* 74.

(4604) JASMINUM AURICULATUM: AURICULATED JASMINE.

Juhi, HIND.

A small sweet flowered species much cultivated at Ajmeer.—*Genl. Med. Top. p.* 172.

(4605) JASMINUM CHRYSANTHEMUM OR REVOLUTUM: CURLED FLOWERED YELLOW JASMINE.

Pela Chambeli, HIND.

Cultivated and is a very free flowerer and highly ornamental.—*Genl. Med. Top. p.* 172.

(4606) JASMINUM GRANDIFLORUM, CATALONIAN JASMINE.

Chambeli, Jaty, HIND.

Much cultivated at Ajmeer for the flowers.—*Genl. Med. Top. p.* 172. *J. grandiflorum* has opposite pinnate leaves, leaflets bluntish, the outer ones 3- to 5-confluent, buds horizontal. It is a native of the East Indies, and greatly resembles *J. officinale*, except in the size of the leaflets and in the exterior ones being confluent and the flowers larger and reddish underneath. Both this and the former species yield the true essential oil of jasmine of the shops. This species is very much prized by the natives of India; the large white flowers having a most powerful scent, and being in blossom throughout the year, are used as garlands on all festive occasions.—*Riddell.* This Catalonian, or Spanish Jasmine, is the most exquisitely fragrant species of the genus, and is very generally cultivated by both Burmans and Europeans.—*Mason.*

(4607) JASMINUM NUDIFLORUM Mr. Fortune tells us that, in the north of China there are a number of plants which have their flower-buds very prominently developed in autumn, so much so that they are ready to burst into bloom before the winter has quite passed by, or, at all events, in the first dawn of spring. Amongst these, Jasminum nudiflorum occupies a prominent position. Its yellow blossoms, which it produces in great abundance, may be seen not unfrequently peeping out from amongst the snow, and reminds the European stranger in these remote regions of the beautiful primroses and cowslips which grow on the shaded banks of his own land. Nearly as early as this the pretty daisy-like Spiræa prunifolia: the yellow Forsythia viridissima, the lilac Daphne Fortunei and the pink Judas-tree, become covered with blossoms, and make the northern Chinese gardens extremely gay.—*A Res. among the Chi. p.* 241.

(4608) JASMINUM ODORATISSIMUM. The yellow Jasmine; and elegant shrub with small shining leaves, flowers bearing a sweet scent, a native of Madeira, introduced into India.—*Riddell.*

(4609) JASMINUM OFFICINALE, Common Jasmine, is a Native of the South of Europe. It has opposite leaves, pinnate; leaflets ovate-accuminate; buds erectish. The plant is glabrous, the branches angular. Calycine segments 5, subulate; corolla white, 4 or 5-cleft, sweet-scented; the terminal leaflet is the longest. The common Jasmine has been a favourite wall-shrub from time immemorial. Its native country, as well as the date of its introduction, are unknown. Gerarde in 1597 says it was in common use for covering arbours. There are golden and silver-edged leaved varieties of the common Jasmine, as well as a double flowered variety.—*Eng. Cyc.* It is used generally for covering trellis work by Europeans. The natives grow it in bushes, and use the flowers at most of their festivals. It is propagated by layers; the plant does not require any particular care, further than watering.—*Riddell.* A perfumed oil, is prepared from this with the fixed oil of the *moringa*. Dr. Jackson has given an interesting account of this in a paper drawn up for the Indian Materia Medica and published by the Editor in the Journal of the Asiatic Society for 1839.—*O'Shaughnessy, p.* 436.

(4610) JASMINUM PUBESCENS. DOWNY LEAVED JASMINE.

Koond, HIND.

Is cultivated as a flower, and is very ornamental, but, it is curious that the flowers of Ajmeer, with a light soil have no scent, while at Hooshungabad in a stiff black soil the flowers in the mornings are highly odoriferous.—*Gen. Med. Top. p.* 172.

(4611) JASMINUM REVOLUTUM, AND OFFICINALE, the Common White Jasmine.

(4612) JASMINUM SAMBAC. Lin. Double Jasmine.

Mootya, HIND.	Kudda mulla, HORT. MAL.
Koday Mullie poo, TAM.	Bela, HINDOOIE.
But moogra DUK.	Navamallica, SANS.
Zam bak, PERS.	
Boondoo Mallie, TEL.	

This beautiful and very fragrant flower is commonly called by the English the double Moogrie.—*Ains. Mat. Med. page* 159. This Jasminum sambac, single flowered Arabian sambac, is a twining plant. Leaves almost jasmine, membranous, from cordate to oblong, acute or obtuse, glabrous; berries globular; branches, petioles, and peduncles downy. It is a native of the East Indies. The flowers generally form small trichotomous umbellets, white and fragrant The berries are black. A perfume, known as Oil of Jasmine, is obtained from this species.—*Eng. Cyc.* There are two varieties and one is *Jasminum Sambac, plenum*, the great double Arabian Jasmine. The rich lobed branches of this variety are studded all over like the snow-drop tree with lovely white flowers, the size of small roses, and delightfully fragrant.—*Mason.* The Arabian Jasmine is probably more universally cultivated than any other flower. The

common double variety is more generally seen, but the single flowered, with a twining habit is not unfrequent.—*Mason.* At Ajmeer the largest double variety is called, "hazarea mogra" and was brought to Ajmeer from Cawnpore. The single is called "motiga." The beautiful varieties are cultivated there called "Satha" with single and double flowers, which have the odour of fine green tea. These are probably the Jasminum scandens of Willdenow, —*Irvine's Med. Top.* In the fields in the vicinity of Foo-Chow-foo large quantities of Jasminum Sambac are cultivated. It is used to decorate the hair of the Chinese ladies and to garnish the tables of the wealthy. Mr. Fortune believes that all Chinese gardens, both in the north and south are supplied with this favourite flower from the province of Tokein. Various other shrubs such as Murraya exotica, Aglaia odorata, and Chloranthus inconspicuus, are grown for their blossoms, which are used for mixing with the tea.—*Fortune's Wanderings, page* 382.

(4613) JASMINUM SYRINGAFOLIUM. WILD JASMINE. There is wild climbing jasmine seen throughout the Tenasserim Provinces festooning the forests, and arching the pathways with its delicate flowers, like a wreath of snow flakes flung over the arms of a Canada spruce.—*Mason.*

(4614) JASMINUM UNDULATUM. The leaves of these are slightly bitter. The root of *J. pubescens* is thought to be elexiteric.—*Eng. Cyc.*

(4615) JASPER.

Jaspis, DUT.	Diaspro, IT.
Jaspe, FR.	Jaschma, RUS.
Jaspiss, GER.	Jaspe, SP.

This stone occurs usually in large amorphous masses, sometimes in round or angular pieces; its fracture is conchoidal, and its colours are various. It is usually divided into four species, denominated *Egyptian* jasper, *striped* jasper, *porcelain* jasper, and *common* jasper. It is sometimes employed by jewellers in the formation of seals. *McCulloch—Faulkner.* Jasper is a handsome stone for inlaid work, and admits of a high polish, but is not used as a gem. It is a siliceous rock, containing, according to Beudant, silica 93.57 per cent., peroxide of iron 3.98, alumina 0.31, lime 1·05. water 1.09. It is coloured red by the peroxide, and yellow or brown by the hydrate of iron. It also occurs of green and other shades. When striped with green, yellow, red, or brown, it is called *riband jasper.* When these colours are in irregular concentric zones, it is called *Egyptian jasper.* Another variety is called *ruin jasper,* when a variety of brown markings appear on a dark ground. Jasper is nearly equal to agate in point of hardness, and is subject to the same treatment as cornelian in the lapidary's art.—*Tomlinson.*

(4616) JATROPHA, a genus of plants belonging to the natural order *Euphorbiaceæ.* It has monœcious flowers: a 5-parted or lobed calyx; corolla 5-parted or absent; stamens 8 or 10, with unequal monadelphous filaments; styles 2, bifid or dichotomous: capsule 3-coccous.—*Eng. Cyc.* Nearly all the Jatrophæ are powerful cathartics. Fee cites *J. gossypifolia,* America, *J. glandulosa,* Arabia, and the *J. multifida,* or coral plant, (Avellana purgatrix, *grand ben purgatif*) a native of America and India, a shrub 8 or 10 feet high, replete with acrid bitter juice, with large pinnatifid glabrous leaves, the fruits slightly pyriform, about the size of a nutmeg; a single seed is said to be purgative Lindley says it is "one of the best of the emetics and purgatives, acting briskly without inconvenience, and the effects readily allayed by a glass of white wine." Dr. O'Shaughnessy, still considers it a very dangerous article.—*O'Shaughnessy, page* 558. Dr. Wight gives Jatropha *peltata,* 1196.; villosa, 1169

(4617) JATROPHA CURCAS. PHYSIC NUT. Vern.

Caat-amu-nak, TAM.	Napatain, TEL.
Bag Barendee, BENG.	

Grows in New Andalusia, Havanna, India. Fruit oval, size of a small nut, yellow or blackish, containing three whitish bivalve, monospermous seeds.—*O'Shaughnessy.* Physic-Nut is a very common small tree, or bush, on the coast of Coromandel. The bark is smooth and light ash-coloured: leaves scattered stalked, broad, cordate, 5-angled, smooth, about 6 inches each way; petioles round, smooth, 4 to 6 inches long; stipules absent; panicles terminal or from the exterior axils cymose, bearing many small yellow flowers. The male flowers at the extremities of the ramification on short articulated pedicels, and the female ones in their divisions with their pedicels not articulated. Bracts, a small one below each subdivision of the panicle, and generally one pressing on the calyx: calyx 5-leaved; corolla 5-petaled, campanulate, somewhat hairy; disc of 5 glandular bodies round the base of the filaments; filaments 6, the central one very thick, columnar, the 5 exterior ones filiform towards the base, adhering to the central one, all erect, and a little longer than the calyx; anthers 10, sagittate, equal: 5 supported by the large general filament, and 1 by each of the others. The leaves are rubefacient and discutient; warmed and rubbed with castor-oil, they are applied by the natives of India as poultices. The seeds are violently emetic and drastic; their expressed oil is reckoned a good application in itch and herpes, and also a little diluted, in rheumatism. The milky juice is considered detergent and healing; it dyes linen black. The oil boiled with oxide of iron forms a varnish used by the Chinese for covering

boxes. In large doses the seeds are energetic poisons.—*Eng. Cyc.* The physic-nut tree is often seen in cultivation in Tenasserim and its juice dyes linen black.—*Mason.* The leaves warmed and rubbed with castor oil are used as a poultice to hasten suppuration: seed excessively drastic. The milky juice boiled with oxide of iron makes fine black varnish. The same idea exists as to the acridity of the castor oil, namely, that the embryo is the source of this quality, and that by removing the embryo the nut becomes bland and alimentary; MM. Fee and Humboldt support this opinion. The physic nut is a powerful cathartic, one seed, or three or four drops of the expressed oil, being a sufficient dose.—*O'Shaughnessy, p.* 558. A beautiful pale yellow oil is procured from the seeds of the angular-leaved physic-nut. It is used by the natives in medicine and as a lamp oil. About 700 tons of this oil was imported into Liverpool in 1850 from Lisbon, for the purpose of dressing cloth, burning &c.—*Simmonds.* In the Dekhan, this plant is used as a hedge from its easy growth: it flowers in the rains.—*Riddell.*

(4618) JATROPHA GLANDULIFERA, is a native of the East Indies. The leaves about the extremities of the branchlets are alternate, petioled, and generally palmate; the lobes from 3 to 5, oblong, serrate, with each serrature ending in a short green glandular-headed bristle; stipules bristly, many-cleft, each division ending in a glandular head; panicles terminal, about as long as the leaves. Male flowers most numerous and terminal, small, of a pale yellowish-green colour. The female flowers few, and subsessile in the divisions of the panicle. The pale or whey colored thin juice, which exudes from a fresh wound, is employed by the Hindoos as an escharotic to remove flaws from the eyes. Common in gardens above Calcutta; *Roxb.*—*O'Sh. p.* 559.

(4619) JATROPHA GLAUCA. GLAUCOUS LEAVED PHYSIC NUT.

Addale or Authaulay yennai, TAM.

J. glauca is found in Arabia Felix. It has leaves from 3-5-lobed, mucronate, serrate, toothed; petioles naked; stipules palmate, with setaceous branched divisions, glandular at the apex. The seeds yield a stimulating oil recommended by the Hindoos as an external application in cases of rheumatic and paralytic affections.—*Eng. Cyc.* Seeds yield a stimulating oil, used as an external counter-irritant.—*O'Shaughnessy.* This, which in appearance approaches castor oil, seems to be but little known. It is fluid and light straw colored, and is procurable in South Arcot, where the plant grows in waste land. It is now chiefly used medicinally as a counter irritant, but if procurable in sufficient quantity seems likely to prove an useful oil.—*M. E. of* 1855.

(4620) JATROPHA MULTIFIDA. CORAL PLANT, is a native of tropical America. It has palmate 11 lobed smooth leaves, the segments wedge-shaped and pinnatifid; stipules setaceous, multifid; flowers corymbose, scarlet, with coloured pedicels. The seeds are one of the best of all emetics and purgatives, acting briskly, but without inconvenience; their effects are readily stayed by the administration of a glass of good white wine.—*Eng. Cyc. Vol.* III *page* 303. Though a native of America, the coral plant, with its brilliant carmine corymbs is considerably diffused in Maulmain grounds.—*Mason.* This shrub is common in almost all the gardens; and is known by its resemblance to the substance from which it is named. The seed is sometimes eaten by children, but is of a deleterious nature, and an emetic should be immediately administered. The inspissated juice forms a substance like caoutchouc. —*Riddell.*

(4621) JATAMANSI VALERIAN. JATAMANSI, BALCHUR: VALERIANA JATAMANSI. Roots of Nardostachys Jatamansi.

(4622) JAVA. In 1851, the aggregate value of Imports and Exports of the Island was £8,761,980. It has a population of 10,000,000, with 461 inhabitants to the square mile.—*Crawfurd.*

(4623) JET, BLACK AMBER, PITCH COAL.

Git, Zwarte-barnsteen, DUT.	Gagat, GER.
Jais, Jayet. FR.	Gagata, Lustrino, IT.
	Gagus, LAT.

Jet is found in detached fragments in the amber mines in Prussia, Germany, France, and Spain: it is also found at Whitby, Scarborough, and Yarmouth, and is also imported from Turkey. The finer and harder pieces are worked into brooches, armlets, studs, rosaries, necklaces, &c. It is also sometimes used as an ingredient in varnishes and cements.—*Faulkner.* Jet is a variety of bituminous mineral coal, harder than cannel coal, of a deeper black colour, and possessing a higher lustre. It receives a brilliant polish, and is worked in the same manner as alabaster. In jewellery, the use of jet in mourning ornaments is very considerable It can be turned with most of the ordinary tools, and worked with files and saws. Before the polishing, it appears of a brown colour, but after that process, it attains a beautiful and brilliant black.—*Tomlinson.* Jet occurs sometimes in elongated reniform masses, and sometimes in the form of branches, with a woody structure; fracture conchoidal; soft and brittle; specific gravity but little greater than that of water; lustre brilliant and resinous: colour velvet black, opaque. It is found in Saxony and also in the Prussian amber-mines, in detached fragments. The coarser kinds are used as fuel; it burns with a greenish flame and a strong bituminous smell, and leaves a yellowish ash.—*Engl. Cyc. Vol.* III. *page* 303.

(4624) JERUSALEM ARTICHOKE. This is a species of sun-flower, a native of South

America. It goes to seed generally in October and November, and may be raised from it, or by dividing the root, planting them the same as potatoes. They should be put down in January or February, and will require occasional watering until the rains, when they make their appearance. As the plants grow they must be well earthed up, and if very tall, may probably require to be supported with sticks. This vegetable is ripe as soon as the stalk withers, and the best method of preserving them is to let the roots remain in the ground,—that is, if the white ants and other insects do not attack them. If you are obliged to take them up, keep them in a safe place, in earth, watering them occasionally. To sow them, put either a half or a whole one, at a foot distance, in rows, the same as potatoes, and attend to them in like manner.—*Riddell.*

(4625) JERUSALEM SAGE. Phlomis.

(4626) JETEE OR CHITTEE FIBRE, "Rajmahal Bowstring creeper," grows there in dry barren places. Its dried milky juice serves as a caoutchouc. Its fibres are made into thread, twine, bow-string, and rope. It belongs to the family Asclepedeæ.—*Royle Fib. Pl.*

(4627) JETTAMANSI, SPIKENARD.

(4628) JETTIMAD, LIQUORICE ROOT.

(4629) JETTIMAD KA RUS, LIQUORICE JUICE

(4630) JHALL, NETS.

(4631) JHEELS. Near Churra, the common water plants of these Jheels are Vallisneria serrata, Damasonium, 2 Myriophylla, 2 Villarsiæ, Trapa, blue, white, purple and scarlet water-lilies; Hydrilla, Utricularia, Limnophila, Azolla, Salvinia, Ceratopteris, and floating grasses.—*Hooker, Him. Jour. Vol.* II. *p.* 309.

(4632) JEWELLERY. Workers in iron and steel could never have found difficulty in managing gold and silver, for which indeed the East has always been famous. Working in gold was familiar to the Egyptians before the exodus of Israelites. That the Hindoos have long been familiar with its applications we find in the hymns of Rig Veda, where golden armour and golden chariots, and decorations of gold and jewels, are frequently mentioned. The variety of ornaments and of arms which have been displayed show their skill in working it up. Mr. Hamilton sent from India a series of specimens of gold and silver in different stages, to show the process of making gold wire. The rose chain from Trichinopoly, and the snake chains sent by the Rajah of Vizianagrum, all displayed great skill in the workmen, as also the silver filagree work from Hyderabad, for which Cuttack and Dacca are most famous, and display greater delicacy and beauty than either Genoa or Malta. Much of the Indian jewellery being peculiar in form, and in the ways in which it is worn, is not much admired in Britain as the skill of the workmen otherwise deserved. The articles usually made in filagree work are bracelets, earrings, brooches, and chains, groups of flowers, uttardans, and small boxes for native uses. Mr. Taylor says, "the design best adapted for displaying the delicate work of filagree is that of a leaf; it should be drawn on stout paper, and of the exact size of the article intended to be made. The apparatus used in the art is exceedingly simple, consisting merely of a few small crucibles, a piece of bamboo for a blow-pipe, small hammers for flattening the wire, and sets of forceps for intertwisting it." The art of making gold wire, that is, silver covered with gold, is practised in various parts of India, as Dacca and Hyderabad, as well as Delhi and Benares. "Several varieties of gold and silver thread (*badla*) are made at Dacca, as *goolabatoon* for the embroidery of muslins and silks; *goshoo* for caps and covering the handles of chouries; *sulmah* for turbans, slippers, and hookah-snakes; and booiun for gold lace and brocades." Much fringe of various patterns is made, and thin tinsel stamped into various forms of flowers, or impressed with excellent imitations of jewels, such as flat diamonds, emeralds, and rubies. Many of the ornaments are made only for the poorer classes, for instance, imitations of precious stones, ornaments in pewter, in shell, and lac, and still simpler, a bracelet with straw to represent the gold, and the red seeds of *Abrus precatorius* in the place of garnets.—*Royle Arts. &c. of India. pages* 509 *and* 510.—The following are the names and uses of a few of the Jewels of Southern India:

Vunkee, or Armlet.
Jumpaloo, or Ear Jewel.
Kutree Paval, Ear ornament.
Vallels, or Bangles.
Nuthoo, Nose Jewel.
Moothoo Coopoo, or Ear ornament.
Patteel, or Bangles.
Coopy, or Head ornament.
Mayer Mootha, Ear jewel.
Jadabillay, or Head ornament.
Adega, Neck ornament.
Curdapoo, or Head ornament.
Thallysaman, or Head ornament.
Gaya or Geddy Gooloosoo, or Leg ornament,
Jaga Undoo, or Head ornament.
Cummul and Jemeeka.

(4633) JONESIA, a genus of Plants of the tribe *Cassieæ* and of the natural family of *Leguminosæ*, which was named by Dr. Roxburgh in honour of Sir William Jones, who, in the midst of his numerous other avocations, found time to pay attention to Indian plants. The species are few in number, and indigenous in the islands of the Malayan Archipelago, as well as the eastern frontier of Bengal, that is, in Silhet and lower Assam. They form trees which are highly ornamental from their handsome shining abruptly-

pinnate leaves, and from the showy nature of their crowded racemes of flowers.—*Eng. Cyc. Vol.* III. *page* 303.

(4634) JONESIA ASOCA, the best known species, is often referred to by Hindoo poets by the name which has been adopted by botanists to distinguish it as a species. Dr. Roxburgh says, and we can in a great measure coincide with him in opinion, "When this tree is in full blossom, I do not think the whole vegetable kingdom affords a more beautful object." Flora Indica II. p. 220.—*Eng. Cyc. Vol.* III. *page* 303. When Dr. Wallich found the Amherstia, it was growing beside a Jonesia, and though it be but little diffused over our garden plots, yet its symmetry, and numerous bunches of red and orange flowers certainly entitled it to companionship with that celebrated tree. Gaudama, it is said, was born under this tree; and within the fall of its shadow, he delivered his first harangue. "At the instant of his birth," say the Burman sacred books, "he walked seven steps, and with a voice like the roaring of the king of lions he exclaimed. 'I am the most excellent of men. I am the most famous of men. I am the most victorious of men."—*Mason.*

(4635) JUBBULPORE HEMP. Crotolaria tenuifolia, is a perennial plant a native of Coromandel, which grows to 6 or 9 feet high and yields the fibre known in England and Calcutta as Jubbulpore hemp. It is considered equal to Russian and bears a heavier weight.

Kind and quality of rope.	Size.	Government Proof.			Breaking weight.		
	Inches.	Cwt.	qr.	lb.	Cwt.	qr.	lb.
Oiled Jubbulpore Hemp, Artillery Traces, ...	3	36	0	0	43	2	0
Untarred do, superior four Strand, plain laid, ...	3½	42	0	0	83	0	0
Untarred Dhunchee (Aeschynomene Cannabina Rox), Sesbania aculeata, ...	3½	49	0	0	75	0	0
Pine apple fibre, ...	3¼	42	0	0	57	0	0

A good deal of the value of this plant is supposed to be the result of the climate and soil in which it is grown. See CROTOLARIA TENUIFOLIA.

(4636) JUGLANDACEÆ, *Juglands*, are a natural order of Apetalous Exogenous plants, consisting of trees or shrubs having eatable nuts and somewhat resinous leaves. The former are the walnuts and hickory nuts of the markets; the first produced by the genus *Juglans*, the latter by that called *Carya*. The leaves are alternate and pinnated; the flowers usually monœcious, those which are male collected in catkins. The calyx of the latter consists of a few scales attached obliquely to a single bract, and surrounding a variable number of stamens; that of the females is superior. The ovary is one-celled, and has one solitary erect ovule, which changes into a 4-lobed seed, with crumpled cotyledons, inclosed in a 2-valved nut, clothed with a fleshy epicarp. The Common Walnut (*Juglans regia*), a native of Persia, is well known for its excellent timber, from which musket-stocks (and formerly cabinet-work) are manufactured, for its agreeable wholesome nuts, and the sweet drying oil which they furnish when pressed. *Carya alba*, the White Hickory, bears nuts like those of the walnut, only smaller, smoother, and with a thicker shell, and furnishes a valuable tough elastic white timber much employed in the construction of carriages and other vehicles. Other species of Hickory are also eaten, especially the Pecan Nut, the produce of *Carya olivaformis*, a small and delicate sort. Although the fruit of these plants is eaten, it contains a purgative principle, which renders some of the species cathartic, as is the case with *J. cathartica* and *J. nigra*, two North American species; and even the common walnut participates so much in this quality, when the fruit is young, that a laxative conserve well known in domestic medicine is prepared from it. *J. nigra*, the Black American Walnut, is a tree of remarkable size and beauty. The species are chiefly found in North America, a few are East Indian, one species a native of Persia and Cashmere, another of Caucasus, and a third of the West India Islands. There are 4 genera and 27 species. —*Eng. Cyc.*

(4637) JUGLANS, a genus of Plants belonging to the natural order *Juglandaceæ*. All the species are large trees. The flowers are unisexual, and those containing the stamens and pistils are found on the same tree. The stameniferous flowers are arranged in cylindrical drooping solitary catkins, which are developed from buds borne by shoots produced the year previous to that in which the catkin appears. The calyx is composed of 5 or 6 scales, which are attached to a bractea at a distance from its base and tip. The stamens are from 18 to 36 in number. The pistiliferous flowers are solitary, or only a few in a

group, and are terminal on a shoot developed in the same year. The calyx is ovate, including the ovary, and adhering to it, except at the four-toothed tip. The petals are 4, small, and inserted into the free part of the calyx. The ovary has one cell, and one erect ovule. The stigmas are two or three, and fleshy, scaly, with glands. The fruit a drupe. The covering of the nut is a fleshy husk of one piece that bursts irregularly. The nut is woody, consisting of two valves. The seed single, erect, lobed, wrinkled. There are four species of *Juglans*, three of which are natives of North America and one of Asia. The genus *Carya*, to which the hickory-trees belong, was formerly included under *Juglans*, but was separated by Nuttall. The species of *Juglans* are much more rapid in their growth than those of *Carya*, and are furnished with only simple aments.—*Eng. Cyc.*

(4638) JUGLANS REGIA, the Royal or Common Walnut-Tree, Akrot; Char-mughz; is the oldest and the best known of the species Its leaves are furnished with from 5 to 9 oval glabrous obscurely-serrated leaflets. The fruit is oval, and seated on a short inflexible peduncle. The nut is rather oval, and uneven. It is a native of Persia, in the province of Ghilan on the Caspian Sea. It was also seen by Loureiro in the north of China; and Palsal, who saw it in Taurida and south of the Caucasus, supposed it indigenous there. The Walnut-Tree was known to the Greeks under the name of Persicon, Basilicon, and Caryon. It is uncertain at what time it was first cultivated in Europe, but it was cultivated by the Romans before the death of the emperor Tiberius. Its wood was much valued by the Romans, and the nuts were also eaten. There is no history of the intrduction of this tree into Great Britain, but it is now very commonly cultivated there, although it fails to propagate itself by its seeds. It is only however in the southern and middle parts of England that the walnut brings its fruit to perfection. The walnut, when full-grown, is a large handsome tree with strong spreading branches. Its trunk is thick and massive, and covered with a deeply furrowed bark; the branches are of a gray colour, and smooth. The leaves, when bruised, give out a very peculiar aromatic odour and in the heat of summer this scent is sometimes so powerful as to produce unpleasant effects on persons who approach these trees. The foliage is graceful and light, and of a bright yellowish-green colour, which contrasts well with trees having foliage of a darker shade. Its leaves are almost the latest to appear, and the first to fall. It grows very rapidly and vigorously in the climate of London, and trees will attain a height of 20 feet in ten years. It sends down into the earth a large tap-root, with numerous branches, and, on account of the size and strength of the root, there is no tree more able to resist the effects of wind, or better adapted for exposed situations. It is said that plants will not grow under its shade; this probably arises from the bitter properties of its leaves: when they are not allowed to accumulate, the shade of the walnut does not appear more injurious than that of other trees. The uses of the walnut are very various. Before the introduction of mahogany and other woods, the wood of the walnut was held in higher estimation than that of any other European tree. It is on this account that it was so extensively cultivated in England and on the continent three or four centuries since. The timber of the walnut is light, a cubic foot weighing when green 58½ lbs., and when dried scarcely 47 lbs. When the tree is young, the wood is white, and in this state very much subject to be worm-eaten; but as the tree grows older, the wood becomes more compact, and is of a brown colour, veined and shaded with brown and black. In France and Germany it is still much used by turners, cabinet-makers, joiners, coachmakers, and musical-instrument markers, who prefer the wood which has grown on poor hilly soils. The wood of the roots is the most beautifully veined. One of the most important uses of walnut-timber is the making of gun-stocks. For this purpose it is well adopted on account of its strong lateral adhesion, its lightness, and its not being liable to splitting or warping in the working. The demand for walnut-wood for this purpose was immense during the last war on the continent, and it was stated in 1806 that France required 12,000 trees annually for the making of guns. The government of France still maintains large plantations of walnut-trees for supplying her army with gun-stocks. In England the walnut has seldom been used except for the higher-priced fire-arms, but such was the demand for it for that purpose at the beginning of the present century, that single walnut-trees were sold for as much as 600*l*. This led to the importation of walnut-timber from the Black Sea, and also of the timber of the black walnut from America, so that the cultivation of the tree as timber is almost at an end in England. The walnut is of more value at the present day on account of its fruit than of its timber. In almost every stage of its growth the fruit of the walnut is used for the table. When young, green, and tender, it is pickled and preserved with the husks on. About the end of June they may be preserved with or without their husks. "The green and tender nuts," says Gerarde, "boyled in sugar and eaten as suckade, are a most pleasant and delectable meat, comfort the stomach, and expell poyson." When they are about half ripe, a liqueur is distilled from them, which is considered to possess medicinal properties. In August, before they are quite ripe, the French eat them in what they call 'cerneaux,' scooping out the kernel with a knife, and eating it with vine-

gar, salt, pepper, and shallots. When the nuts are fully ripe, which is generally at the end of September or the beginning of October, the kernel, deprived of its investing skin, is eaten in great quantities. As long as the skin can be easily removed they are a nutritious and healthy article of diet; but when they get dry, so that their skins stick to them, they become indigestible. In no part of England do they constitute an important article of diet, but in many parts of France, Spain, Germany, and Italy, people live during the season of their ripening almost entirely on walnuts. A great number of the walnuts consumed in England are of foreign growth. In 1831 there were imported from France and Spain 23,578 bushels, which then paid a duty of 2s. per bushel. As they are now free of duty, the importation is not registered. On account of the large consumption of the fruit, both as an article of diet at home and for exportation, the walnut-tree is still largely cultivated in many parts of the continent. The district of the Bergstrasse on the Rhine, between Heidelberg and Darmstadt, is almost entirely planted with walnut-trees. Evelyn states that such is the importance attached to the growth of this tree, that "in several places between Hanau and Frankfort in Germany, no young farmer is permitted to marry a wife till he brings proof that he is a father of a stated number of walnut-trees; and the law is inviolably observed to this day for the extraordinary benefit which this tree affords the inhabitants." The fruit of the walnut is commonly gathered by thrashing the tree with a long pole. By many this process is thought to be beneficial to the tree, and barren walnut-trees are often thrashed to make them bear. But although barren trees may be made to bear by reducing the excessive growth of their shoots by breaking them off, it is no proof that the same process is good for healthy-bearing trees. The natural process of separating the fruit from the tree is undoubtedly the best, and gently shaking the branches till the fruit falls has been recommended by many walnut-growers as much preferable to thrashing. The nuts should be gathered at the time they easily fall out from the husk, and then exposed to dry for a day or two in the sun. The best mode of keeping the nuts fresh for eating is to bury them in dry soil or sand, so deep as not to be reached by frost or the heat of the sun, or by rain: or they may be placed in dry cellars, and covered with straw. "When the nut is to be preserved through the winter for the purpose of planting in the following spring, it should be laid in a rot-heap as soon as gathered, with the husk on; and the heap should be turned over frequently in the course of the winter." (Loudon.) The albumen which constitutes the bulk of the seed of the walnut contains an oil, which is used in large quantities, especially

on the Continent. It is obtained by reducing the seeds to a pulp by means of a stone wheel and basin, and then expressing the oil, first without heat and then by the application of heat. The oil requires great care in keeping, as it becomes tainted by slight changes in the state of the atmosphere. That which is cold-drawn keeps best, and is alone used for the purposes of diet. It has however always the taste of the walnut, which is to some persons disagreeable. The oil obtained by heat is used by artists, and also for lamps. Artists use this oil in mixing white, or any delicate colour: and they prefer it on account of the rapidity with which it dries. In copper-plate printing also, in Paris, walnut-oil is considered indispensably necessary in order to obtain a fine impression, whether in black or in colours. For this purpose the oil is prepared in various ways, according to the several colours with which it is to be mixed. In all cases it is reduced in bulk by boiling or by setting fire to it, so as to reduce it to the required consistency. One bushel of nuts, it is said, will yield about 7 lbs. of this oil. The mass which is left after the oil is expressed is made into cakes, and used as food for sheep, and poultry, and in some places it is made into candles, which give a tolerably good flame. The husks and root of the walnut both yield a dye, which is much used by gipsies and theatrical performers for staining the skin brown. It is also used by cabinet-makers and joiners to stain white and yellow woods of a dark-brown or black colour, like that of the walnut. In the preparation of the dye from the husks they should be allowed to rot, and then boiled in water, adding to the decoction fresh water, according to the colour required to be produced by the solution. The sap of the walnut-tree contains a large quantity of saccharine matter; and in some countries the trees are tapped for the purpose of obtaining the sap, which by evaporation is converted into sugar. It is also in many parts of Europe and Asia fermented and made into wine, and a spirit is also distilled from it. The leaves of the walnut, as well as other parts of the tree, contain a large proportion of alkali in them and in some parts of France they are collected and burned for the sake of the potash contained in the ashes. The bark of the leaves, the husks, and the oil of the walnut have all been used in medicine, and had at one time a great reputation, All parts of the plant, excepting the albumen of the seed, posses a bitter principle, which acts as a tonic and an anthelmintic, and has been its great recommendation as a medicine. Cowley, in his 'Plants,' sums up the virtues of the walnut in the following lines:—

"On barren scalps she makes fresh honours grow.
Her timber is for various uses good:
The carver she supplies with useful wood.
She makes the painter's fading colours last.
A table she affords us, and repast.
E'en while we feast, her oil our lamp supplies.

The rankest poison by her virtues dies;
The mad dog's foam and taint of raging skies.
The Pontic king, who lived where poisons grew,
Skilful in antidotes, her virtues knew."

Anglers employ an infusion of the leaves or husks for pouring upon the earth, in order to procure worms, which it speedily brings to the surface.—*Eng. Cyc.*

(4639) JUGLANS TRICOCA.

Ta-soung-let-wah, Burm.

Scarce, but found on the banks of the streams in the Pegu district. It is a hard strong timber. Wood, white colored, adapted to every purpose of house-bulding.—*McClelland.*

(4640) JUJUBES. A fruit of the plum kind, produced in the South of Europe, Persia, and other countries. The Asiatic is much darker than the European kind, which is of a reddish yellow colour. The best are fresh, plump, and well dried. The term is also applied to a composition sold by confectioners, consisting of gum-arabic, sugar, &c., and used to allay coughs, colds &c.—*Faulkner.*

(4641) JUMALGOTA. Croton Tiglium. A small tree, leaves alternate ovate cordate, from three to five inches long and two or three broad; yields the croton oil.—*Jaffrey.*

(4642) JUNCACEÆ. Rushes. "The *Juncaceæ*, or true rushes, are insipid and inodorous; several are employed for mechanical purposes only, as the common rush, for making mats, baskets, and the bottoms of chairs, while the pith is employed for the wicks of rushlights. *Juncus effusus*, which is the common European species, is, according to Thunberg, cultivated in in Japan for making floor-mats. *J. glaucus* a European species found in the Himalayas, and closely allied to *J. effusus*, might be employed for all the purposes of the common rush." ('Illust. Himal. Bot.,' p, 401.) Rushes are found in moist places on the mountains of India. —*Royle, Fib. Pl. p.* 60.

(4643) JUNCUS, a genus of Plants belonging to the natural order *Juncaceæ*. This genus is distinguished by its inferior perianth, composed of 6 glumaceous leaves; its 3-celled, 3 valved capsules, the seed bearing dissepiments of the valves being in their middle. The species are numerous, and are found mostly in moist, boggy situations in the colder parts of the world; are however inhabitants of tropical regions.—*Eng. Cyc. Vol.* III *p.* 309. Wight gives J. Lamprocarpus.

(4644) JUNIPER BERRIES.

Hub-ul Hoober, Arab.	Baies de Genievre, Fr.
Geneverbessen, Dut.	Cocole-di-Ginepro, It.
Wacholder-beeren, Ger.	Embro, Sp.

The well-known fruit of the *Juniperus communis*. These berries have stimulating and diuretic properties, and are an article of the *Materia Medica*, but are chiefly used in the distilleries in England and Holland for flavouring Gin or Geneva.—*Waterston.* The berries which are procurable in the Indian bazars, are supposed to be brought from the Himalayas and Cabool.—*Faulkner.*

(4645) JUNIPERUS, a genus of hardy evergreen woody Plants, belonging to the natural order *Coniferæ*. Its distinctive character consists in its female fructification being succulent, consolidated, and reduced in the number of its parts below what is usual in the order to which the genus belongs. Like other *Coniferæ*, its fruit is composed of scales representing carpels spread open, and collected in a spiral manner round a common axis. But they are not more than six in number, generally three, and when ripe are fleshy, and consolidated into a body resembling a drupe. In the language of the Pharmacopœia they are berries, in that of botanists they are termed *Galbuli*. About 20 species are known, *J. excelsa* and *J. Chinensis* are handsome hardy trees; *J. Lusitanica*, the Goa Cedar, is also of great beauty, because of its drooping habit and light gray branches, but it will not live long in England, except in the warmest of the southern counties; and *J. Phœnicea* is a handsome bush; the others are of little moment.—*Eng. Cyc.*

(4646) JURIPERUS CHINENSIS. This low spreading shrub has been brought from China and cultivated in gardens.—*Eng. Cyc.*

(4647) JUNIPERUS COMMUNIS, the Common Juniper, is a common bush, with long, narrow, sharp-pointed leaves, which are concave and glaucous on the upper side, but convex and green on their under, and with blackish fruit. It grows wild in all the northern parts of Europe, and, as is said, in North America also and the north of India, but it is doubtful whether the plants called Juniper by travellers in the Himalaya Mountains are not some other species. Occasionally the Juniper becomes a small tree. The fruit is used in considerable quantities in the preparation of gin, and in medicine as a powerful diuretic; a kind of beer called genevrette is also obtained in some parts of France by fermenting it with barley. The words 'gin' and 'Geneva' are derived from the French name of this species Genevre. Oil of Juniper, obtained from the *Galbuli*, is said to be a useful diuretic.—*Eng. Cyc.* According to Dr. O'Shaughnessy, the Common juniper, was found by Captain Webb on Netee Pass, called *bilhara, pudma, pumaroa;* and by Mr. Inglis in Kunawur—3 to 6 feet high, forming a dense, diffuse, irregular bush, occasionally tree-like, and attaining an elevation of 20 feet. Odour of the leaves agreeable and balsamic, of the berries also agreeable, taste of the leaves resinous, rather bitter; of the berries sweet, aromatic, slightly saccharine, hot, and rather bitter. The berries

(*Abhul* and *Hoober*,) in bazars are considered diuretic and emmenagogue; brought from the Himalayas and Cabul. *Arkonus* and *baratee* are assigned as Greek names.—*Royle*, *p* 352. The berries alone are now employed in medicine; these contain sugar, mucilage, and a little essential oil. The oil is white or yellowish, light, very liquid, of hot and acrid juniper taste, and very strong smell; the extract of the berries is called a "Rob." The oil is prepared on the large scale in Holland, and is often adulterated with turpentine. The chief consumption of juniper berries is, however, for the flavouring of the spirit called *gin*. Besides its stimulating and narcotic properties, *gin* is also acknowledged to be a powerful diuretic.—*O'Shaughnessy*, *p*. 620.

(4648) JUNIPERUS EXCELSA, is according to Royle, the Himalayan cedar.—*O'Shaughnessy*, *page* 620. Juniperus Excelsa, forms a fine tree; and is used in Britain as an ever-green.—*Eng. Cyc.*

(4649) JUNIPERUS RECURVA. The weeping blue juniper (*Juniperus recurva*, Deschoo"), and the arboreous black one (called "Tchokpo") yield beautiful wood, like that of the pencil cedar, but are comparatively scarce in Sikkim.—*Hooker Vol.* II. *p*. 45.

(4650) JUNIPERUS SPHÆRICA. On one of Mr. Fortune's excursions amongst the hills he met with a curiously formed tree, which at first sight seemed to confirm the old Virgilian tale of apples growing upon plane trees. It was one of those junipers which grow to a considerable size in the north of China, and which the Chinese are fond of planting round graves.—*A Res. among the Chi. p.* 68.

(4651) JUNK. A Malay and Javanese word applied to the larger craft of the Archipelago, used both in war and for commercial purposes. The word is properly Ajong or Jong corrupted by the Portuguese into Junco which the English have improved into Junk, and apply to the larger Chinese vessels. The Chinese word for the vessels we call Junks, is Wang-kang.—*Crawfurd.*

(4652) JUREMA BARK. An astringent substance, the product of the *Acacia jurema*, a native of Brazil.—*Faulkner.*

(4653) JURKUNDALOO, Kundaloo; and Kubra, a large nettle, growing in the northern and middle parts of the Himalayas. It grows about eight or nine feet high; and the natives make ropes of the fibre, for tying up their cattle and snow sandals.—*Royle Fib. Pl.*

(4654) JUSSI FIBRE, and striped Jussi dresses from Manilla, were exhibited in the Exhibition of 1851; the plant yielding the fibre is not known.—*Royle Fib. Pl.*

(4655) JUSTICIA, a genus of Exogenous Plants belonging to the natural order *Acanthaceæ*. The species of this genus inhabit all the tropical parts of the world, preferring however damp woods to dry and open plains. It is especially in the forests of Brazil and India that they occur. Many of them are never woody, some are bushes or small trees, and a small number are valued by gardeners as objects of ornament. As limited by Linnæus the genus comprehended a very discordant collection of species; modern writers have accordingly broken it up into many new genera. As now limited, *Justicia* itself scarcely contains a plant of any importance. As among the species now removed from *Justicia* to other genera there are some which are useful as medicinal agents, especially in India, it may be as well to mention them here, instead of referring to genera which are not yet generally known. Thus *J. Adhatoda*, celebrated in Sanscrit works by various names, as Vidiumatri, Vasika, &c., has been called *Adhatoda Vasika*, and is chiefly esteemed as a demulcent in coughs. *J. nasuta* is now *Rhinacanthus communis*, and is much employed in Indian medicine, especially for the cure of ringworm and other cutaneous affections, mixed, according to Dr. Roxburgh, with lime-juice and pepper. It is also one of their remedies for snake-bites, but is no doubt inefficacious for such purposes. *Andrographis* (formerly *Justicia*) *paniculata* is the best known and probably the most valuable of all, as one of its names, Muha-tita, implies Chief, or King of Bitters: it is also very commonly called Kalup-nath, and well known to Europeans in the peninsula of India by the name of Creyat, or Kreat, and has been prescribed with benefit as a bitter in this country. It forms one of the ingredients of the Drogue Amere, which is well known in India, and at one time obtained considerable repute as a cure for cholera; but it can be useful only as a stimulant and tonic—*Eng. Cyc.* Lindley also quotes *J. pectoralis*, as stomachic. *J. biflora*, and *Acanthus mollis*, having emollient leaves are used for poultices, (*O'Shaughnessy*, *p* 482.) and Wight gives J. linida.—*Gen. Med. Top. p.* 124.

(4656) JUSTICIA ADHATODA. Malabar Nut Justicia. Now Adhatoda Vasika.

Arus, Alusa Bakus, Vasooka, Hind.

This plant, now become Adhatoda vasika, grows abundantly wild: and common all over India. Leaves are used at Ajmeer, and are considered diaphoretic and sedative, and used in cough prescriptions. The root is used in Ceylon as an emmenagogue and to cause abortion. The charcoal of the plant is used to make gunpowder.—*Irvine's Top. of Ajmere pp.* 124, and 173.

(4657) JUSTICIA COCCINEA.—This is a species bearing a small pink flower. The leaves are of a reddish colour underneath. It is said by the natives that the root is an antidote to the bite of a snake, and that it is the root sought after by them when bitten by the cobra.—*Riddell.*

(4658) JUSTICIA ECBOLIUM. *Roxb. Fl. Ind. i.* 114.

Jati, Oodoo-Jathe. HIND.

A native of the Indian forests, said to be diuretic. Flowers pale blue, tube very long and slender. A shrubby plant.—*O'Shaughnessy.*

(4659) JUSTICIA GANDURUSSA, WILLOW LEAVED JUSTICIA. Lin.

Jugut-mu Kali-Shumbali, HIND	Caur Noochie, TAM. Neela Nirghoondie, SANS.

A handsome shrubby plant with bark of a dark purple hue very smooth, and in some varieties green, flowers during the rains, it grows readily by cuttings or slips: the leaves when rubbed have a strong and not unpleasant smell; they are roasted and given by the natives in chronic rheumatism.—*Riddell.* It is cultivated in the Kotah gardens; also found in Fakeer's plots. —*Genl. Med. Top p.* 172. Ainslie tells us it is used by the Vitians in decoction, in chronic Rheumatism attended with swellings.—*Ains. Mat. Med. p.* 73.

(4660) JUSTICA NASUTA. WHITE-FLOWERING JUSTICIA. It is now called Rhinacanthus communis.

Kabuter ke jhar ka jurr, HIND.

A shrubby plant with white flowers in axillary and terminal panicles; grows spreading along the ground. The leaves are bruised and used by the natives for curing ringworm.—*Riddell. Genl. Med. Top. page* 173. Found in the native gardens as a flower. The flowers are sold along with those of Jasmine, and the root used in medicine as an excitant.

(4661) JUSTICIA PICTA. PAINTED JUSTICIA.

Soorkh-Vasooka, HIND.

This is a very ornamental and handsome variegated shrub, bearing red flowers, having green, leaves with large white spots fringed with green, and some varieties with red and dark red spots. The leaves are used for the decoration of the dessert after dinner, and other ornamental purposes: few leaves can be found on which some grotesque resemblance to the human countenance may not be fancied or traced.—*Riddell. Genl. Med. Top. p.* 173.

(4662) JUSTICIA PANICULATA. NAT. CREYAT. This plant grows wild in the southern parts of India. It is highly prized as an excellent stomachic. Seeits present name ANDROGRAPHIS PANICULATA.

(4663) JUSTICIA VERTICILLATA. ERECT JUSTICIA.

Kustoola, HIND.

Found in the Kotah jugles.—*Genl. Med. Top. p.* 173.

(4664) JUTE. JEW'S MALLOW. (Corchorus Olitoreus and C. Capsularis.)

C. Olitoreus.

Sans. Putta, BENG. Pat: fibre, JUTE.	Cloth, TAT. Chotee, megila, VERN.

C. Capsularis.

Isbund, HIND.	Ghi-nalita pat fibre Naltapat, BENG.

There is a variety called by the natives Teetah Pat. This fibre has long been known in India, in the manufacture both of cordage and cloths, but it was only during the past fifteen years that it has come to be used in England. It is the product of the two distinct plants above named: both of them common all over India, and Ceylon and China, are cultivated for their leaves, and under shoots, as pot herbs, and for their fibres. The C. Olitoreus, is the Jew's mallow, and is supposed to be the plant alluded to in Job, XXX, 4. There is a variety which the natives call Bem Pat. Some of the Jute lately imported into England, has been twelve feet in length, in bales of about 4 cwt. bound round with ghunny cloth. Jute is easily spun: It is now much used to mix with codilla. It is made into "Ghunny"; cloth (*Megili*), cordage, and paper and well bleached samples of damask have been seen manufactured from its fibres. Cloth made of Jute is said to be more durable than that fabricated from cotton. It brings, according to quality from £13 to £22 per ton, in the English market. The fibres are subdivisible into very fine fibrils, which are easily spun: they are long, soft and silky, and under the microscope, cannot be distinguished from those of flax, to all the purposes of which the jute fibre is applicable. When prepared by steeping, the plant requires long maceration, a fortnight or three weeks being scarcely sufficient for it. The chief sites of its cultivation in the Bengal Presidency, are Malda, Purnea, Natore, Rungpore and Dacca, and four varieties are distinguished, *Pat, Tasa, Mesta and Coshta.* Merely local names as at Jungpore the names given to Jute are, Ghore Sun (probably Hibiscus) 2 *Paut* 3 Cooch Murda Paut and 4 Amleeah Pat, (probably Crotolaria). In the culture the land is prepared as for rice, the plants are weeded when a foot and a half high, and it is cut close to the roots when it has flowered, and before the seeds are ripe, a few plants being left to allow the seeds to come to maturity. After the plants are cut down, their tops are clipped off, and fifty to a hundred tied together. These bundles are laid in a shallow tank and weighed and allowed to remain for eight or ten days, being daily examined to ascertain that they are not unduly rotted. When the bark is found to separate and the stalk and fibres become soft, the bundles are opened; and five or six stalks taken in the hand at a time, by the person standing in the water, who breaks off about two feet of them from the bottom; the bark, which has become soft like thread is held in both lands, and the

stalks are taken off. The fibres are separated by mere washing, are dressed and exposed to the sun to dry, by hanging them over bamboos. They are afterwards partially cleaned, and finally made up into bundles of from one to two maunds, for the market. The culture of Jute has of late years greatly improved in many places; the produce is stated to be from 400 lbs. to 700 lbs. per acre. Jute has been noticed, which, see at length under the article CORCHORUS.

K.

(4665) KACOOTA KALUNG.

Kacoota kalung, TAM.

This root Dr. Ainslie had never seen, nor could he learn that the Botanical name of the plant has been ascertained.—*Ainslie, p.* 249.

(4666) KADOLL. A rather hard, fine, close grained, heavy Ceylon wood. Specimen, much worm-eaten.

(4667) KADOMBAIRIA. A rather hard, fine, close-grained, somewhat, light Ceylon wood; its surface curiously veined.

(4668) KADOOMBA. A soft, though fine, close-grained, and rather light Ceylon wood.

(4669) KÆMPFERIA, a small genus of India *Scitamineæ*, or *Zingiberaceæ* of some authors, of which the species are indigenous to the islands of the Archipelago and the southern parts of the continent of India, as Bengal and the districts on its eastern frontier. All are furnished with tuberous roots like the turmeric and ginger plants. The spikes of the flowers are short and rising from the root, in some species before, in others with, and nestled among the leaves; all are highly ornamental, and *K. rotunda*, called by the natives Bhooi Chumpa, or Ground Chumpa, is much cultivated in gardens on account of the beauty and fragrance of its flowers. It was supposed to yield the round Zedoray of the shops, but incorrectly, as Dr. Roxhurgh thinks, since he considers his *Curcuma Zedooria* to be the plant. So *K. Galanga* was, equally incrrectly, long supposed to yield the Galanga of the shops. It is a native of the mountainous districts beyond Chittagong, and there called Kumula, and is cultivated by the Mugs; by them it is sold to the people of Bengal, who use it as an ingredient in their betel. The roots possess an agreeable fragrant smell, and a somewhat warm, bitterish, aromatic taste. The Hindoos use them, according to Dr. Roxburgh, not only as a perfume, but also medicinally. The roots of *K. angustifolia* are, according to the same authority, used as a medicine for cattle by the people of Bengal. Dr. Wight gives Kæmpferia (Vol. VI, page 15) Galanga 899; rotunda 8029; in Icones.

(4670) KÆMPFERIA CANDIDA. WHITE KÆMPFERIA. During the dry season, a white-flowered species of kæmpfera with a yellowish limb, is often seen lifting its crocus-like flowers without a single leaf, on the most arid spots in the jungles of Tenasserim.—*Mason.*

(4671) KÆMPFERIA GALANGA. GALANGA KÆMPERIA. Roxb. i. p. 15.

Chundra moola, BENG,

Common all over India. Rhizoma fleshy, tuberous, with fleshy fibres; the roots are agreeably fragrant, and of warm bitterish aromatic taste. Notwithstanding its specific name, it is not the source of the true *galanga* root of the druggists, a drug now known to be the produce of the *Alpinia galanga.—O'Shaughnessy, p.* 650. The roots of this plant may be often seen attached to the necklaces of Karen females, for the sake of their perfume. They also put them with their clothes, and use them to a small extent medicinally.—*Mason.*

(4672) KÆMPFERIA ROTUNDA, FRAGRANT KÆMPFERIA, Roxb. i. p. 16.

Booi Champa, BENG.

This species is cultivated all over India, and was long considered to produce the *Zedoaries.* Fee still refers them to it. But Lindley, with most other writers of authority, states that this article is the root of the *Curcuma zedoaria.—O'Shaughnessy, page* 650. This is the finest species of the genus, and is cultivated by amateurs for its beautiful sweet-scented blossoms. A nearly related species is indigenous in the Karen jungles.—*Mason.*

(4673) KAI MOOLINGHIE, TAM. This pot vegetable Dr. Ainslie had never seen but he understood that the upper and edible part of the plant has somewhat the taste of a radish; the root is not eatable.—*Agriculturists' Nomenclature, Vol.* II. *page* 240.

(4674) KAKRASINGHEA, is officinal with both Hakims and Hindoo doctors at Lahore. In the Materia Medica of the latter, its use has been handed down from olden times. These are vegetable excrescences and probably produced by the deposit of eggs of a certain insect on that kind of Rhus which is found in abundance in the north-west of Hindostan.—*Thirty five years in the East, Dr. Honig. p.* 335.

(4675) KALADANA, OR MIRCHAI. Seeds of Pharbitis cærulea, Indian substitute for jalap.

(4676) KALA KUSTOORIE. Abelmoschus Moschatus. Musk Okro.

(4677) KALA NIMUK. Black salt is made by pounding together five seers of suji khar, two seers of dried anola fruit, and one maund of common salt, adding water, and boiling for some time: is considered to promote digestion: is much eaten: used in many mesalihs.—*Gen. Med. Top. p.* 144.

(4678) KALAN. MUSHROOM. Agaricus campestris. Lin.

Kalan, TAM.	Poota ghonkooloo, TEL
Kootay ke chitrie, DUK.	Surpachitra, SANS,

(4679) KALI, the name of the maritime plant from the ashes of which soda is obtained by lixiviation; and from the name of this plant, with the Arabic article *al*, is derived that of a class of substances possessing peculiar properties, which are called alkalies. Kali was also formerly employed to designate the alkali Potash. —*Eng. Cyc.*

(4680) KAM ALOO, HIND. Dioscorea Alata. —Winged Yam. Tubers oblong, brown on the surface, internally white of a great size. Besides the tubers, the proper roots of all those plants are fibrous, springing chiefly from and about the union of the stems with the tubers, and spreading in every direction.—*Riddell.*

(4681) KAMARUNGA, fruit of Averrhoa carambola.

(4682) KANARI OIL. Mr. Crawfurd in his History of the Indian Archipelago speaks most favorably of an oil obtained from the Kanari, a tree which, he says, is a native of the same country as the sago palm, and is not found to the westward though it has been introduced to Celebes and Java. He has not been able to distinguish its botanical name; but Mr. Crawfurd describes it as a large handsome tree and one of the most useful productions of the Archipelago. It bears a nut of an oblong shape nearly the size of a walnut, the kernel of which is as delicate as that of a filbert, and abounds with oil. The nuts are either smoked and dried for use or the oil is expressed from them in their recent state. It is used for all culinary purposes and is purer and more palatable than that of the coco-nut. The kernels mixed up with a little sago-meal are made into cakes and eaten as bread. —*Simmond's Comml. Product, page* 546.

(4683) KANDLE, the Tamil name of a Ceylon tree which grows to about fourteen inches in diameter, and twenty-four feet high. It is used at times in house-work.—*Edye. Ceylon.*

(4684) KANJUREA, the Tamil name of a Ceylon tree which grows to about sixteen inches in diameter, and ten or fifteen feet high. The natives use it at times in house-work. It produces a fruit which is used as a medicine.—*Edye. Ceylon.*

(4685) KANOJ. Seed of a small tree brought from Pali and Delhie: considered heating and constipating taken as a condiment, and also given as a medicine in diarrhœa: one seer for two rupees.—*Gen. Med. Top. p.* 141.

(4686) KANOOR. Sheathing bases of the leaves of Crinum asiaticum, v. toxicarium.—*Ben. Phar.*

(4687) KAOLINS are porcelain earths, procurable in great abundance in Southern India, at Ahtoor in Salem: near Chingleput: also near Little Mount, and at Trivatoor and Nuttum in Chingleput, at Triputty in North Arcot: at Bangalore, Cuddapah, Chittoor, Dindigul: Bellary, Neilgherries, Bimlipatam; Travancore; between Vellore and Arnee. Madras: Coringa; Madura, Chicacole;

Dirty yellowish white kaolin, ...	Procurable near Chingleput.

Cream coloured kaolin,...	Procurable in Ahtoor and Salem.
Cream coloured kaolin,...	Procurable in Neilgherries.

Kaolin or Porcelain earth has been observed in parts of Malabar.—*M. C. J.*

(4688) KARANGALLE, the Tamil name of a Ceylon tree which is more generally known to the English by that of "Ebony." It may be procured at Trincomalee in great quantities, but that which is near the water-side is very small. The largest may be about nine inches in diameter, and from ten to twelve feet high: it is used for chairs and house furniture. On the Malabar coast this tree is named Charu Maram. It grows to about ten inches in diameter, and from fifteen to twenty feet high, but the black heart of it does not exceed seven inches in diameter. In the north part of Malabar, in Canara, it is named Acha Maram, by some of the Kanatakas Nugagha. The natives use the young buds, leaves, and flowers of this tree in cases of flux and in inflammation of the liver, for the cure of which it is said to be most useful. At Point de Galle, a great deal of the Ebony and Kalamandel wood is exported to England.—*Edye, Ceylon.*

(4689) KARKAKARTAM VYER. CLITORIA TERNATEA.

(4690) KARTUMA, the Tamil name of a Ceylon tree which is considered to be the Wild Mango. This tree grows to about two and a half or three feet in diameter, and twenty-four feet high. It is used for canoes, native boats, &c. The fruit is very acid, and is sometimes made use of by the lower class of natives in cookery.—*Edye. Ceylon.*

(4691) KARTU NEDENARI, the Tamil name of a Ceylon tree which grows to about fourteen inches in diameter, and fifteen feet high. It is used by the natives for their huts. It is not very durable, and is of little value.—*Edye, Ceylon.*

(4692) KARTU TANGIE, the Tamil name in Ceylon of the jungle cocoa-nut. It grows to about twenty inches in diameter, and twenty five feet in height. The fruit of this tree is of no use, and the trunk is of little value.—*Edye, Ceylon.*

(4693) KARTU TODA, the Tamil name in Ceylon of the wild or jungle orange tree; it grows to from ten to sixteen inches in diameter, and ten feet in height. It is a very handsome yellow wood, its fruit is of no use.—*Edye, Ceylon.*

(4694) KARUCUE WAEH, the Tamil name of a Ceylon tree which is very close grained and heavy. It is used for the frames of native vessels, and is considered a good strong wood. It grows to eighteen inches in diameter, and twelve to fourteen feet in height.—*Edye, Ceylon.*

(4695) KARUDU, the Tamil name of a Ceylon tree which the natives use in boat-work. It is not durable, and is of little value.—*Edye, Ceylon.*

(4696) KATAMANAK.

Katamanak, TAMIL. | Miniley, PORT.

This tree grows to about thirty feet in height, and two feet and a half in diameter. It can be obtained in great quantities. It is used by the natives for planks in vessels, and is considered valuable; but from what I have seen of the stock in a store at Trincomalee-yard, I am of opinion that it is only applicable to inferior purposes in the dockyard and ships.—*Edye, Ceylon.*

(4697) KATHALAY is the Tamil term applied to the Agave vivipera, the manufacture of fibres from which has been successfully accomplished in the Bangalore jail. The name of "silk grass" also is applied to these fibres as well as to those of the A. yuccæfolia. The fibres of the A. vivipera are said to equal in strength the best hemp. The A. cantala of Roxburgh is supposed to differ little from the A. Americana and its fibres could be equally turned to use. (*Syn.* Pita. Pita Kalabuntha. Cantala. Bans-keora.) As the economic uses to which all the parts of a plant can be put, are of much importance to the success of all agricultural operations, we may mention that, *Fourcroya gigantea* (Ventenat), known as the Sheemay Kathalay, is not an Aloe, although its fibre is usually so denominated. The fibrous plants here described are not natives of India, but have mostly been introduced from America. They are capable of enduring a great variety of climates, and are all rapidly extending over India, but they are not yet sufficiently abundant, the Fourcroya gigantea, especially, to yield the fibre in large quantities. F. gigantea produces a fibre five or six feet long, somewhat finer than that of the Agave fibres, but possessing similar properties The F. gigantea is less abundant than the Agave, but is as easily propagated, and its leaves attain a length of ten feet.

(4698) KATHBEL. Wood-apple.—Feronia Leaves and fruit of Feronia elephantum.

(4699) KATTUKENDE. A hard, fine, rather close-grained, heavy wood.—*Gen. Med. Top. page* 142.

(4700) KASNI KA JUR, Cichorium endivia, Succory Root, considered warm, stimulating, and febrifuge given in "manjus," the diluent taken preparatory to purging, the seed is used in sherbets, is plentiful about Ajmeer.—*Gen. Med. Top. p.* 142, *Cichorium intybus.* Chicory. Wild succory, Κιχωριον, Diosc. Europe. Leaves radical, oblong, deep green, deeply lobed, lobes toothed, cauline leaves small, sessile, and very entire; inodorous, taste very bitter. The Indian species called *Kasni,* scarcely differs from the *C. Intybus.* The roots contain nitrate and sulphate of potash, mucilage, and some bitter extractive principle. An infusion of succory mixed with syrup causes a thickening of the liquid, and a substance is formed termed by the discoverer, M. Lacarteria—SACCHO-CICHORING GUM.—*O'Shaughnessy, page* 408. Wild Chicory vegetates luxuriantly during the summer in Cashmere, and in the Punjab during the

cold season. The Hakims use the Succory-seeds, which are consequently kept in the bazars.—*Honigberger, page* 256. See CHICORY.

(4701) KAUDESEQUE CHECKE, a Drug.

(4702) KAULFUSSIA AMELLOIDES. This is a small annual plant with bright blue flowers, the florets of which curl back after they have been expanded a short time, it requires a light soil and the seed may be sown at the end of the rains.—*Riddell.*

(4703) KAUNA, the Tamil name of a Ceylon tree which is used for boat crooks, knees, &c. This tree grows to about fourteen inches in diameter, and six to ten feet in height. It is strong and durable, and produces a fruit which is similar to the cocoanut, and is used by the poorer natives as food.—*Edye, Ceylon.*

(4704) KAWUL-GUTTI, NYMPHÆA LOTUS. The seeds of the lotus: they are tasteless; but much used in medicine: mucilaginous: said to check vomiting, six massee are a dose: also roasted as food.—*Gen. Med. Top. p.* 143.

(4705) KAYANN, the Tamil name of a Ceylon tree which is about ten inches in diameter, and fourteen in height: it produces a fruit which is of no value.—*Edye, Ceylon.*

(4706) KEEKUR GUM, produced by *Vachellia farnesiana*—also a variety of Gum Arabic.

(4707) KELINGOO, a name given in Ceylon to the young plant of the Palmyra Tree, Tamul kurung. It is an article of food chiefly in that island and is cultivated for that purpose; the seeds being sown in six to eight layers, under loose sandy soil. When fresh they are roasted, boiled, or sliced and fired like the Bread fruit. When it is to be kept, the parchment like covering is removed, and they are dried in the sun, and kept under the name of "*Odial*" and this when boiled is called "*Poolooc Odial.*" When the odial is reduced to flour or meal, it is used to form the preparation of "*Cool,*" of the Singalese. The Singalese also prepare from kelingoo meal, a dish called "Putoo," which is occasionally eaten with rice, and also with jaggery. It is made of prawns, or fish, scrapings of cocoa-nut kernels and unripe jack fruit. The people of Southern India and Ceylon have for many hundred years been in the habit of eating the pulp or root, which is the first shoot from the Palmyra nut, which forms the germ of the future tree, and is known locally as *Pannam kilingoes.* It is about the size of a common carrot, though nearly white. It forms an article of food among the natives for several months in the year; but Europeans dislike it from its being very bitter. Recent experiments have proved that a farina superior to arrowroot can be obtained from it, prepared in the same way: and 100 roots, costing 2½d., yield one and a-half to two pounds of the flour.—*Simmonds. Seeman.*

(4708) KELON TURPENTINE. Oily product of Pinus or Cedrus Deodara.

(4709) KERMES.

Grein Scharlakenbessen, DUT.	Kermes, Kirmiz, GUZ. HIND.
Scharlachbeeren, GER.	Grana Chermes, IT.
	Grana Kermes, SP.

An insect (*Coccus ilicis*), found in large quantities on a small species of oak in many parts of Asia, and the South of Europe, particularly in Spain. It contains a red colouring principle, and, until the discovery of the cochineal insect, was the only substance used in dyeing scarlet from a very remote period. In Europe it is almost superseded by cochineal.—*Waterston.*

(4710) KENNEDYA. LEGUMINOSÆ. A genus of beautiful plants, with lilac, and crimson coloured flowers, with short keels whilst the K. Coccinea have long ones, they are propagated by seed, in any good soil.—*Riddell.*

(4711) KESRU, HURSINGAR, NYCTANTHES ARBOR TRISTIS. The tubes of the corolla of the weeping nyctanthes, are brought from Mewar, considered heating given in medicine, one tola a dose, used chiefly to dye yellow: two seers for one rupee.—*Gen. Med. Top. p.* 143.

(4712) KHABAJI. Althæa alhugas (chhota gul khairu): Common Mallow. The seed is used as the mallow.——*Gen. Med. Top. p.* 143.

(4713) KHARWA.

Kharwa, GUZ. HIND.

A coarse kind of red cloth, chiefly manufactured in Guzerat.—*Faulkner.*

(4714) KHASSIA. The climate of Khasia is remarkable for the excessive rain-fall. Attention was first drawn to this by Mr. Yule, who stated, that in the month of August, 1841, 264 inches fell, or twenty-two feet, and that during five successive days, thirty inches fell in every twenty-four hours! Dr. Thomson and Dr. Hooker also recorded thirty inches in one day and night, and during the seven months of his stay, upwards of 500 inches fell, so that the total annual fall perhaps greatly exceeded 600 inches, or fifty feet, which has been registered in succeeding years! From April, 1849, to April, 1850, 502 inches (forty-two feet) fell. This unparalleled amount is attributable to the abruptness of the mountains which face the Bay of Bengal, from which they are separated by 200 miles of Jheels and Sunderbunds.—*Hooker, Him. Jour. Vol.* II. *page.* 282.

(4715) KHATMI ALTHÆA ROSEA, (bura gul khaira): Hollyhock. The seed is considered cooling: in medicine one tola is given: the corollæ and pericarps when fresh are exceedingly

mucilaginous and used in sherbets.——*Gen. Med. Top. p.* 143.

(4716) KHEKERA. CUCUMIS SATIVA. Cucumber, common. See CUCUMBER.

(4717) KHUB-KALI, KHUB-KALA. The seed of the yellow fruit of a small tree about Ajmeer ; very mucilaginous : considered refrigerant.—*Gen. Med. Top. p.* 143.

(4718) KHUSKHUS-GRASS. ANDROPOGON ANATHERUM MURICATUS. Both Karens and Burmese cultivate little bunches of this large grass for its fragrant roots.—*Mason.*

(4719) KHUSH KHUSH. PAPAVER SOMNIFERUM. Poppy Seed. This is simply the seed of the poppy and used in confectionary, as well as to make oil.—*Riddell.*

(4720) KILGUTCH, KATKARANJA, KUTKALEJA, GUILANDINA BONDUCELLA : Bezoari nut. The seed is very bitter : used very generally as tonic, febrifuge and deobstruent ; common at Ajmeer : natives foolishly suppose the seed will cure a scorpion sting.—*Gen. Med. Top. page* 143.

(4721) KILIOORUM BARK.

Kilioorum puttay, TAM.	Darshishan, ARAB
Patannie lode, DUK.	Soogundie, SANS.
Kaiyphul, HIND.	

This is a white, slightly aromatic pleasant tasted bark found in many Indian bazars. It is held in high estimation by the Native Practitioners for its stomachic qualities and bears a strong resemblance in its external appearance, to the Canella Alba, but is not nearly so warm or pungent. In Ainslie's time the botanical name of the tree from which it is obtained, had not been, ascertained. Capt. Hardwicke saw the Kaiyphul growing amongst the mountains betwixt Hurdwar and Sirinagar and places it amongst plants of the class Cryptogamia and order Filices : the red fruit of it he says is much esteemed by the Natives.—*Ains. Mat. Med. page* 83.

(4722) KINCHINJUNGA, (forty-five miles distant) from Durjeeling is the prominent object, rising 21,000 feet above the level of the observer out of a sea of intervening wooded hills ; whilst, on a line with its snows, the eye descends below the horizon, to a narrow gulf 7000 feet deep in the mountains, where the Great Rungeet, white with foam, threads a tropical forest with a silver line.—*Hooker, Him. Jour. Vol.* 1 *p.* 122.

(4723) KIN-LE-SUNG. But the finest tree of all, and quite new to Mr Fortune was a beautiful species of cedar or larch, which Dr. Lindley, to whom he sent specimens, called Abies Kæmpferi.—*A Res. among the Chi. page* 266. I have already noticed a new cedar or larch-tree named Abies Kæmpferi discovered among these mountains.—*A Res. among the Chi. p.* 274. It is called by the Chinese, the Kin-le-sung, or Golden Pine, probably from the rich yellow appearance which the ripened leaves and cones assume in the autumn. Although he had often made enquiries after it, and endeavoured to get the natives to bring him some cones, or to take him to a place where such cones could be procured, he met with no success until the previous autumn, when he had passed by the temple from another part of the country. Their stems, which he measured, were fully five feet in circumference, two feet from the ground, and carried this size, with a slight diminution, to a height of 50 feet, that being the height of the lower branches. The told height I estimated about 120 or 130 feet. The stems were perfectly straight throughout, the branches symmetrical, slightly inclined to the horizontal form, and having the appearance of something between the cedar and larch. The long branchless stems were, no doubt, the result of their growing close together and thickly surrounded with other trees, for he had since seen a single specimen growing itself on a mountain side at a much higher elevation, whose lower branches almost touched the ground. He thus concludes the notice of his first sight of this plant. I need scarcely say how pleased I was with the discovery I had made, or with what delight, with the permission and assistance of the good priests, I procured a large supply of those curious cones which were sent to England in the winter of 1853.—*A Res. among the Chi. p.* 275.

(4724) KING WOOD. A fancy wood, the product of a small tree growing in Brazil. It is extremely hard, of a dark chocolate colour, with black veins. It is chiefly employed for small cabinet work.—*Waterston. Faulkner.*

(4725) KINO.

Palass-goond, BENG.	Kino-harz, GER.
Gomme de Kino, FR.	CHINO, IT.

Much uncertainty long existed regarding the origin of this astringent gum, of which there are several kinds. The East Indian, African, Australian, and American varieties, are ascribed to different trees. Kino generally occurs in shining grains, of a rich ruby red colour, nearly all soluble in alcohol, and readily pulverisable between the fingers. In India it is used for communicating a nankeen colour to cotton. It is also an article of the materia medica.—*Waterston. Faulkner.* Kino, is well known as an astringent substance, and occurs in small and shining, brittle, angular fragments of a deep-brown colour, which appears to be a natural exudation of some one plant, from the uniformity of its appearance. Several kinds of Kino are, however, met with in commerce, as well as described in books, as that of *Butea frondosa* from India, at one time acknowledged by the Dublin College and which has no doubt been sometimes imported as Kino. Botany Bay Kino, proceeded by *Eucalyptus re-*

sinifera, or Brown Gum Tree, at one time acknowledged by the Edinburgh College; a Jamaica, and a Columbian Kino, are mentioned; and an extract of Bhatany is sometimes enumerated with them. But a genuine Kino has been supposed to come from the west coast of Africa. There is no doubt however, and the fact may be easily ascertained by any one making inquiries in the proper channels, that the best is now imported into Great Britain from Bombay. Kino seems to have been first introduced into European practice by Dr. Fothergill, in 1757, who states, in a paper in Med. Obs. and Enq. i. 358, that he was indebted for information respecting it to Dr. Oldfield, and that the substance was obtained from the river Gambia, whence he called it *Gummi rubrum astringens Gambiense*. Previous to this, Moon, in his travels into Africa, mentions a red gum as issuing from incisions in trees, and which he mistook for Dragon's blood. Mungo Park discovered that the tree which yielded this substance was called Pao de Sangue (Blood-tree) by the Portuguese. His specimens were determined by Mr. R. Brown to belong to *Pterocarpus erinaceus*,—a tree which has since been well figured and fully described in the Flore de Senegambie. The origin of the name Kino has not yet been satisfactorily ascertained. It was introduced into the E. P. 1774 as *Gummi Kino*, and into the L. P. 1787 as *Resina Kino*. Dr. Royle has long been of opinion that the name was derived from the Indian *kuenee*, or *kini*, applied to a similar exudation from the bark of *Butea frondosa*, of which the Sanscrit name is *Kin-suka* (*Himal. Bot.* p, 195, and *Proc. Royal Asiatic Soc.* p. 50, May, 1838), because this *Butea gum* had been sent as Kino to the above Society from Bombay. An old specimen in the India House is marked *Gum Cheena*. Dr. Pereira, several years since, found this "in the warehouse of an old drug firm in London a substance marked *Gummi rubrum astringens*," which he was told had formerly fetched a very high price. It is, however, very distinct from the Kino of commerce, which, for many reasons, Dr. Royle was inclined to think was the produce of *Pterocarpus marsupium*. Dr. Pereira states that what he calls *East Indian Kino* is always regarded in commerce as *genuine Gum Kino*, and that an experienced East Indian broker assured him it was the produce of the Malabar coast. He also traced it to Bombay, and to Tellicherry, on that coast. In the official reports of the commerce of Bombay, the Kino exported to this country appears to have been previously imported from the Malabar coast. Dr. Royle's attention was again especially turned to this subject on finding in the India House specimens of Kino marked from Anjarakandy, which he recognized as being identical with the present Kino of commerce; but was unable for some time to ascertain the locality of Anjarakandy, until informed by Mr. Dyer (*v.* p. 304) that it was the name of a farm within a few miles of Tellicherry,—that is, near the very place to which Dr. Pereira had traced the East Indian Kino. Since then he discovered that this was formerly one of the East India Company's plantations, under the superintendence of Mr. Brown, and was visited by Dr. Buchanan, in January 1801 (*Mysore* II. p. 544), when he states, numerous valuable experiments were carrying on in the plantation. Having thus determined the place, the next point was to ascertain the plant which yielded this kind of Kino, as well as its mode of preparation. This was effected by writing to Dr. Wight, stationed at Coimbatore; and though he did not at first succeed, Dr. Kennedy afterwards sent him specimens of the flower, leaves, and fruit, also a small portion of the wood and of the gum. On inspecting these, Dr. Wight states, "the specimens received along with the letter leaves no doubt that the Malabar Kino is the production of *Pterocarpus marsupium*." Dr. Kennedy writes that he is informed by his friend Mr. J. Brown of Anjarakandy, that "the juice is extracted when the tree is in blossom, by making longitudinal incisions in the bark round the trunk of the tree, so as to let the gum ooze down into a receiver formed of a broad leaf so placed and fixed in the bark as to prevent the gum from falling on the ground. From the leaf it is made to run into a receptacle placed under the leaf to receive the gum. When this receptacle is filled, it is removed, the gum is dried in the sun until it crumbles, and then filled into wooden boxes for exportation." Dr. Gibson had already stated (see the above *Proc.* p. 59) that "Kino was the produce of *Pterocarpus marsupium* (*beula* or *bia*), a tree very common below the Ghats;" also that the Kino is exported in considerable quantities from the Malabar coast. Dr. Roxburgh, however, was the first to direct attention to this tree, which, he states, exudes a red juice, which hardens into a strong, simply astringent, brittle gum-resin, of a dark red colour, strongly resembling that of the *Butea frondosa*; so that the same analysis might serve for both. He further observes, that the specimen of the gum Kino tree (*P. erinaceus*) in the Banksian herbarium is exceedingly like this plant. The specimens of the Indian and of the African Kino were, as we have seen, the produce of two distinct species of *Pterocarpus*, or perhaps even of four species as it would appear from Mr. Mason's remarks below. *P. Marsupium*, *Roxb.* (Fig, 62.) is a lofty tree, with the outer coat of the bark brown, inner red, fibrous and astringent; leaves subbifarious, alternate, leaflets 5—7 alternate, elliptic, emarginate, above shining and of a deep green colour, from 3 to 5 inches long: panicles terminal; petals white with a tinge of yellow, long clawed, all waved or crested on the margins; stamens ten,

united into one body near the base, but soon splitting into two bodies of five each; ovary generally two-celled, legume long-stalked, the under three-fourths orbicular, the upper side straight; the whole surrounded with a waved veined membranous wing, rugose and woody in the centre, generally one, sometimes, two-celled; seed solitary kidney-shaped. Roxb. Corom. Pl. ii. *t.* 116; Fl. Ind. iii. p. 234. It is a native of the Circar mountains and forests of the Malabar coast, apparently also in those of the foot of the Himalayas, according to Buchanan Hamilton. Kino is in small, irregular, somewhat angular, glistening fragments, of a dark-brown or reddish-brown colour, brittle, and affording a powder which is lighter-coloured than the masses. It is without odour, and has a bitterish, highly astringent, and ultimately sweetish taste. It is not softened by heat; cold water dissolves it partially, boiling water more largely, and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. Alcohol dissolves the greater portion. It consists chiefly of a peculiar modification of Tannin, with Extractive matter, and in some of the varieties of a minute proportion of Resin. According to Vauquelin, it contains no Gallic acid, but Tannin and peculiar extractive 75, red Gum 24, insoluble matter 124. Its aqueous solution, is precipitated by Gelatine (with which it produces a green colour, in consequence of the presence of a little *Caluchine*), by soluble salts of Iron, Silver, Lead, and Antimony, by the Purmuriate of Mercury, and by the Sulphuric, Nitric, and Muriatic acids. The alkalis favour its solubility in water, but essentially change its nature, and destroy its astringent property.—*Royle, page* 370. It has already been mentioned that in 1839, Dr. A. Gibson of the Bombay Medical Establishment, stated that this astringent is produced by the *Pterocarpus marsupium* of Roxburgh, and was at that time an article of export from the Malabar Coast. Long ago Dr. Roxburgh had said that "the specimen of the gum kino tree, in the Banksian Herbarium, is perfectly like P. marsupium.") Dr. Pereira was about the same time assured by an experienced East India broker, that kino was produced in the Malabar forests; while Dr. Royle ascertained by inspecting the official reports of the commerce of Bombay that kino had been imported in 1835-36 to the extent of 36 cwt. Subsequent inquiries of Professor Royle, Dr. Pereira and Dr. Wight have entirely confirmed the statement of Dr. Gibson, and established the fact that all the kino of British commerce is really the produce of Malabar, and is prepared near Tellicherry, chiefly by those enterprising merchants the Messrs. Brown of Anjarakandy. The mode practised in Malabar according to Royle, is as follows:—"The juice is extracted when the tree is in blossom, by making longitudinal incisions in the bark round the trunk of the tree, so as to let the gum ooze down into a receiver, formed of a broad leaf so placed and fixed in the bark as to prevent the gum *from falling* on the ground. From the leaf it is made to run into a receptacle placed under the leaf to receive the gum. When this receptacle is filled, it is removed, the gum is dried in the sun, until it crumbles, and then filled into wooden boxes for exportation."—*Pharmaceutical Journal*, May 1846, p. 500. The *Pterocarpus marsupium* is one of the most lofty and striking trees in the Indian forests—it is well described by Roxburgh, in the *Flora Indica*, Vol. iii. p. 234—and figured in his *Coromandel Plants*, ii. *t.* 116. It yields from incisions a large quantity of blood-red juice, which on being simply exposed to the sun, hardens and then quickly cracks into little angular masses, and crumbling fragments which constitute, without further preparation, the kino of the shops. Specimens of the exudation sent by Dr. Cleghorn to Professor Christison in 1846, from Mysore, were considered by him "quite identical with the kino of commerce." The tree abounds not only near Tellicherry, but along the whole Malabar Coast. Dr. Cleghorn has seen it both in the ascent of the Eastern and Western Ghauts. Dr. Wight sent to him specimens from Coimbatore, and Roxburgh found it in the N. Circars. Buch. Hamilton mentions it under the name of *Vijaya* as occurring in Nepal and also to the eastward of Bengal. The vernacular names are as follows: Beuba, Bia, Beebla, *Duk*; Whoay, *Can.*; Yegy, Vayga, *Beng.* It has been observed in the Concans, (Graham.) Rajpeepla jungles, (Dr. Lush:) Assam, (Voigt). The tree being thus widely diffused, and the exudation procurable in *large quantity*, it may possibly come into extensive use in *dyeing* and *calico-printing*. The product can be obtained with facility by simply incising the bark, and requires no outlay, save that of collecting. "There is no good recent analysis of E. I. Kino showing the propertion of its astringent principl, but it is obviously great." (Christison.) Kino agrees closely with catechu in its action, and like it is a pure and energetic astringent. It is undoubtedly serviceable in dysentery and sore-throat, and is a valuable adjunct to the list of country medicines.—*Cleghorn*. According to Dr. McClelland, the Gum kino from India is supposed to be obtained from *Pterocarpus marsupium*. But as the articles sold as *kino* are produced from trees of four different families of plants, and come from many opposite parts of the world, it is probable that the properties on which their value depends are of a general nature, and therefore that *P. dalbergioides*, equally with *P. marsupium*, affords the *Gum kino* of India, and this opinion is also entertained by others. *P. dalbergioides* is found in the northern parts of the Pegu province in the Prome district chiefly in the vicinity of towns and inhabited

places, rarely in the Forests.—*McClelland.* According to Mr. Mason another Kino gum tree, Pterocarpus Indicus in Tenasserim, is a majestic evergreen, whose yellow papilionaceous flowers clustering amid the bright drooping foliage, scent the air, like the large magnolias, for several hundred yards around. It is propagated by simply planting large branches in the ground at the commencement of the rains. There are, however, two species, the red, and the white, as distinguished by Burmese—the red producing the finest timber, but the white padouk is by far the finest ornamental tree.—*Mason.* In the Journal of the Asiatic Society for August 1848, Dr. Royle, in a valuable article on gum kino, ostensibly enumerates all the various regions from which it has been imported into England; but does not mention it as being a product of the Tenasserim Coast. Yet long before Dr. Royle compiled that communication, more than one consignment had been made by parties in Maulmain, to houses in London, of gum kino to the amount of a thousand pounds. It was brought to Maulmain by an English merchant from the Shan States, and stated by him, to be the production of the pa-douk, the same tree as the one in Maulmain thus denominated by the Burmans. Several years before, Mr. Mason had directed attention to this tree as producing an astringent gum resembling gum kino, but the medical officer, to whom he submitted specimens, said it was "a kind of dragon's blood." However, after Dr. Morton came to the Provinces, he tried it in his practice, and found it, in its medicinal virtues, identical with the gum kino of the druggists. The next inquiry that arises is for the genus and species of the pa-douk. When Mr. Mason first came to the Coast, all the English residents of his acquaintance called it "Burman senna," and the surgeon of the station told him that he believed it was a species of senna. Dr. Malcom, in his Travels, writes; "Pa-douk: or Mahogany, (*Swietenia Mahogani*) is plenty in the upper provinces, especially round Ava, found occasionally in Pegu." In a native Pali dictionary, found in the Burmese monasteries, pa-douk stands as the definition of *pe-ta-tha-la* and the corresponding Sanscrit word in Wilson's dictionary, is defined *Pentaptera*; but the pa-douk does not belong to that genus. In Piddington's Index, however, *peetshala* stands as the Hindee name, and in Voigt's Catalogue, *pee-sal* is the Bengalee name of *Pterocarpus marsupium*; and this brings us nearer the truth. for pa-douk is a name common to two different species of pterocarpus, but which look so much alike that they are usually regarded as one species. One has "long, waving branches, with their extremities generally much drooping, racemes axillary, flowers numerous, deep orange yellow, and very fragrant, filaments ten [often] united into two equal distinct bodies of five each; stile rather shorter than the stamina; and stigma acute;" which is the description of *P. indicus*; but on full examination I think it is the species described by Dr. Wight as *P. Wallichii* that was marked in Wallich's Catalogue as *P. dalbergioides*. There are, however, several points of difference, but not more than there are between Wight's description, and the coloured drawing that he gives of this same species. In the drawing, the leaflets are pointed wholly unlike our plant, but in the letter-press description there is an exact correspondence—in the drawing, the stamens are represented as divided one way, in the description another, and both modes of division, with some others, are seen here on the same tree. This loose way of describing and figuring plants makes it exceedingly difficult for an out-door botanist to identify nearly allied species with book discriptions, made perhaps originally from isolated dried specimens. The other species has leaflets which correspond both to Roxburgh's description, and to Wight's figure of *P. dalbergioides;* and though it differs in some other respects, yet I think it is the same tree. Both these species produce an astringent gum, but which has been exported for gum kino or whether a mixture of both, which is most probable, he is not able to say; possibly neither. It may be that *P. marsupium* is found in the Shan states, for it grows in Assam, where it would doubtlessly be called pa-douk by a Burman. Be that as it may, it is certain that these Provinces can furnish the commercial world with a large quantity of gum kino. The exudation of our pa-douk, one of the most abundant forest trees, has been proved by experiment, to possess all the properties of gum kino. While the product of the neighbouring provinces, whose only avenue to market is through our territories, has been bought by the London druggists for the gum kino of the Pharmacopœia. See *Pterocarpus Wallichii, and Pterocarpus dalbergioides.—Mason.* Dr. Forbes Royle says of the *Butea frondosa*, that it yields by incisions made in its bark an astringent gum, which was at one time supposed to be the genuine Kino of commerce. It is no doubt possessed of similar properties, is frequently used as such in India, and useful like it in Diarrhœas and advanced stages of Dysentery. It is also used in the art of tanning. It has been occasionally sent to Britain as Kino, and Dr. Pereira found it in an old drug firm, marked *Gummi-rubrum astringens.* Its Sanskrit name is *Kin-suka.* It is commonly known in India as *Kini ke gond*, and also by the name *Kumrkus.* Its chemical characteristics are very like those of the Kino of Pterocarpus. It is very carelessly collected, and therefore often contains impurities. It is remarkable for containing a beautiful red colouring matter, difficult of separation. Analysed by Mr. E. Solly, a portion in the crude state yielded about 50 per cent. of Tannin; but

when purified by simple solution in water, so as to separate the impurities, 100 parts contained 78-26 parts of Tannin, 5-05 of difficultly-soluble Extractive, and 21-67 of Gum, with Gallic acid and other soluble substances. The colour and properties of Tannin vary with the exposure and season of collection.—(*v. Roxburgh, Fl. Ind* iii. *p.* 245, and *Pro. R. Asiatic Soc. May* 1838.)

(4726) KIRE PALLE. A very soft, coarse, open-grained, light Ceylon wood.

(4727) KISMISS. The name given to a small, pale coloured, stoneless grape, when dried, and from which Shiraz wine is obtained. It is produced in Persia, whence considerable quantities are brought to Bombay. It is chiefly used in puddings, as a substitute for currants ; and is also served up with stoned almonds, as an article of dessert.—*Faulkner.*

(4728) KITCHELLY CAPOOR, of CHINA, is a scented root, chiefly used by probound and in the perfumery powders called sicsa, rautha and other purposes, and is also used for the medicines. This is called Kitchelly Kelangoo in Tamil sold at from 40 to 60 Rupees a Candy. That from Malabar, from 28 to 40 Rupees a Candy.

(4729) KITTESOLS, OR KITTYSOLS. the distinctive name by which China paper summer-heads are known. They are an extensive article of Export from China to Bombay, Calcutta, &c.—*Faulkner.* These are a cheap sort of umbrella, made of bamboo frames covered with oiled paper or cheap silk. They are sent to the Archipelago and India in boxes containing 100 umbrellas each, which is estimated to be a pecul. Considering the material they are made of, this sort of umbrella or parasol (for their use is for the most part as a protection against the sun) wear a long time.—*Morrison.* This kind of umbrella, or parasol, made of oiled paper, or cheap oiled silk, is largely exported by the Chinese to India; the article is durable, considering its material, and its cheapness induces a large consumption.—*Williams' Middle Kingdom. Vol.* II. *page* 401.

(4730) KNEVEA, the Tamil name of a Ceylon tree which grows to about eighteen inches in diameter, and fourteen feet long. It is used by the natives in boats and house work.—*Edye. Ceylon.*

(4731) KNITTING, appears to be unknown to the natives of India, though it is well worthy of being taught to them ; as, indeed, it has been in the few girl's schools which the natives have allowed to be established.—*Royle, Arts. &c. of India, page* 504.

(4732) KNIVES.

Messen, DUT.	Churi, HIND. GUZ.
Couteaux, FR.	Facas, PORT.
Messer, GER.	Noshi, RUS.
Coltelli, IT.	Cuchillos, SP.

Well-known articles made of iron and steel. They are used for a variety of purposes as their different names imply, such as table knives, pen-knives, oyster-knives, pruning knives, &c. &c. England is reputed to excel every part of the world in the manufacture of knives, as in most branches of cutlery. London and Sheffield knives are esteemed the most.—*Faulkner.*

(4733) KNOWLTONIA VESICATORIA, used commonly as a blister at the Cape of Good Hope.—*O'Shaughnessy.*

(4734) KOAN, A very hard, fine, close-grained, heavy Ceylon wood.

(4735) KOES OR JACK. A moderately hard, but rather coarse and open-grained, though heavy Ceylon wood of a beautiful saffron yellow colour, emits a peculiar, but by no means unpleasnt odour.

(4736) KOMBHUGRAS. Root of a small plant from Delhi: tasteless; but is heating: one tola is given as a tonic or aphrodisiac.—*Gen. Med. Top. p.* 143.

(4737) KOOCHNAL. HIND. BAUHINA VARIEGATA. Lin. Koochnal is the Hindoostani name of a tree, the beautiful flowers of which are eaten in some parts of Bengal as a delicate vegetable. Grows in the Jungle at Molamputty near Coimbatore.—*Ainslie's Mat. Med. p.* 260.

(4738) KOOLEE BAYNEGUN, SOLANUM LONGUM. Egg Plant, cylindrical. See BRINJAL. —*Riddell.*

(4739) KOOMBHEE (CAREYA ARBOREA) A fibre employed in the Himalayas as slow match for their matchlocks.—*Royle.*

(4740) KOORINJA, the Tylophora asthmatica, a plant of the order Asclepidaceæ, yields a strong, white, silky fibre, resembling flax.

(4741) KOOSSOOM, SAFFLOWER, CARTHAMUS TINCTORIUS, the beautiful red dye called *Koossumba rung*, largely used by the dyers.

(4742) KOTHEELA : TRAGACANTH.

Tshaw, BURM.

Six species of *Sterculia*, four of which, *viz. Sterculid ramosa, S. fœtida, S. campanulata, S. piperifolia*, are very plentiful throughout the Province, and yield a gum which is known in the bazars of Bengal under the name of Kotheela. The other two species, *Sterculia balangas* and *S. calorata*, are not so plentiful. This gum is probably analogous to *Tragacanth*, which Dr. Lindley states is obtained from a species of *Sterculia* at Sierra Leone.—*McClelland.*

(4743) KOOTUB MINAR. This column, stately in its structure and gigantic in its dimensions, is a great feature of attraction at Delhi, and arrests the eye of the traveller from afar. While it towers majestically over every thing around, from a distance its conical point seems to pierce the sky. It is from 225 to about 250

feet high has 378 steps and the diameter at the base is about 50 or 55 feet. It is reputed to be 700 years old, and is in excellent order. About 25 years ago it suffered a little from an earthquake but under the directions of the British government a part of the resources of the state were devoted to the restoration of this emblem of antiquity and it now stands in just as great perfection as ever. It throws out three ranges of circular balconies at different heights and is surmounted by a cupola palisaded by a brass railing, an evidently modern improvement made when the edifice was repaired under European superintendence. This colossal piece of architecture is a polygon, fluted cylindrically as well as angularly in alternate order, and wreaths of Arabic inscriptions entwine its massy circumference, the letters being displayed in high relief of about a foot or more in length. The material of the building is a kind of red sandstone but a portion of the upper part is composed of white marble. It is yet a point at issue whether this singular and stately column owes its origin to Hindoo or Mahomedan. It wears a perfect semblance to the Mahomedan style of architecture, but the old dilapitated and crumbling Hindoo ruins in its immediate vicinity raise strong doubts on the subject; added to which, there is a peculiar column of bell metal which stands close by it, with an inscription, of some Buddhist or Hindoo character, bearing the impression of a cannon ball fired at it, some say by Aurunzebe, and others by the Jauts in one of their early expeditions into Delhi.—*Tour of India by French, p.* 20.

(4744) KRAMERIA TRIANDRA. This plant is a native of Peru, and yields the Rhatany root of the Pharmacopœia; a powerful astringent, but destitute of any other virtues. Under the head of *Diospyros* will be found a most efficient indigenous substitute for this article.—*O'Shaughnessy, page* 211.

(4745) KRIS, the abbreviation of Karis, a dagger or pouiard, the universal weapon of all the civilised inhabitants of the Archipelago, and of a hundred different forms, short or long, with a straight or serpentine blade, and with every variety in the shape and ornament of the hilt and scabbard. Men of all ranks, from the peasant to the prince, wear this weapon, and those of rank when full dressed, two or even four. In Java, even women of rank sometimes wear a small one. The wood is probably Malay, but is now of general adoption through the Archipelago. The Javanese have three native names for it besides the Malay one, and it is found represented on several of the ancient temples of Java. The Kris has even reached the Philippine Islands, for there is no doubt but that it is the same word of the Tagala and Bisaya languages which the Spaniards write cális, and translate "sword."—*Crawfurd Dict. p.* 302.

(4746) KRIS, KREES OR KRITZ? is a root of an unknown origin used in Cashmere, in the process of dyeing nafurmance (jacia?), also medicinally. It is indeed one of the most useful substances. The root, Honigberger had as a sample, from Cashmere, was four inches in length, thick as a finger, knotty, fibrous, with some excrescences, having two barks, the outer very thin, like an epidermis, light brown, the other subjacent, not very thick, of a dark brown color, the root was white and very hard, odor slight but agreeable, flavor bitter, aromatic afterwards pungent on the tongue. The flower is said to be blue.—*Honigberger, p.* 265. The root of some parasitical plant, under the name of kritz, is used in Cashmere to wash the celebrated shawls; soap is used only for white shawls.—*Simmonds' Comml. Product, p.* 574.

(4747) KUCHILA KE MULUNG. A Parasite (Viscum monoicum) found on the Nux Vomica trees of Cuttack; a substitute for preparations of Strychnine—(*O'Shaughnessy,*) and is an extremely powerful narcotic. Its powder is a powerful convulsive tonic, producing the same effects as the strychnic and brucinic preparations.—*Beng. Phar. p.* 406, *and Dis. p.* 376.

(4748) KUDDOO. Cucurbita lagenaria.—Bottle Gourd. This is grown at the commencement of the rains; a good soil is all that is necessary, requiring no further care.—*Riddell.*

(4749) KUEPHUL. Bark of Myrica sapida.

(4750) KULA, the Portuguese name of a Ceylon tree, called in Tamil Kanugha. It is very heavy and close-grained, grows to about twenty-four inches in diameter, and eight feet high. The natives use it for general purposes, and for houses and vessels. It produces a fruit which they eat, and from which they extract an oil which is used as a medicine.—*Edye. Ceylon.*

(4751) KULAEE. PHASEOLUS TRILOBUS. Three-lobed Bean. Sown like other native beans. —*Riddell.*

(4752) KULKUL. Seed of Cassia tora.

(4753) KULLYHAIN, a plant from the fibres of which, the Lepchas near Darjeling, make rope.

(4754) KULMEE SAG. CONVOLVULUS REPENS. Creeping Bind Weed. This grows wild; the leaves are eaten by the natives.—*Riddell.*

(4755) KUL TEAK. TECTONA GRANDIS, VAR. Wynaad about Sultan's Battery, scarce, is considered superior to the common Teak.—*McIvor M. E.*

(4756) KULTHEE. DOLICHOS BIFLORUS. Two-flowered Bean Horse Gram. This is grown in fields after the rains, and chiefly used for cattle; when given to horses it must first be boiled; they soon become very fond of it, and keep in as good condition as upon any other grain.

(4757) KUMRUCK. AVERRHOA CARAMBOLA.

(4758) KUMUT or BARK CLOTH, from the River Baram, supposed to be from a species of Artocarpus, is worn by the Kayans when mourning their dead.—*Royle Fib. Pl. p.* 341.

(4759) KUNKER. A limestone deposited from water: very common in India.

(4760) KUPASSEE. Belonging to the family of Compositæ, we may mention a plant which is remarkable for the under surface of its leaves being covered with a cotton-like tomentum; hence it is called *kupassee*, from *kupas* (a name of cotton). The people in the Himalayas use it as tinder. It is also spun into thread and woven into cloth, of which bags are made. The string, until examined, looks as if formed of fibre. A coarse kind of blanket, called *kurkee*, is said to be made of this substance by the Hill people north of Deyrah. Though curious, this substance is not of much importance.—*Royle Fib. Pl. p.* 301.

(4761) KUPILA, ROTTLERA TINCTORIA. The dust from the capsule of the fruit is used; to dye silk yellow: alum is used as the mordant, considered in medicine as of a warm nature, also anthelmintic; given to children in "dai." Three or four massee are a dose, used in ointments for herpetic eruptions: two and a half seers for one rupee.—*Gen. Med. Top. p.* 142.

(4762) KURBOOZAH. Cucumis melo.—Melon. See MELON.

(4763) KURETIA. A hard, fine, close-grained, heavy Ceylon wood.

(4764) KURROO. Roots of Pneumonanthe Kurroo: an Indian substitute for Gentian.

(4765) KURSUMBUL KE PULLIE. Dolichos lunatus.—Duffin Bean. This is a very fine sort of large bean, and when dressed resembles the Windsor; it is grown like all other beans that require sticks for support.—*Riddell.*

(4766) KURUNDU. Vide Carissa.

(4767) KUSAILOO, KUSAILI. The bark of a small tree, wild about Ajmeer: is tasteless; given to lying-in women to clear the blood and create milk from one to four pices' size from the dose in six or seven days.—*Gen. Med. Top. p.* 142.

(4768) KUTIRA. The native name of a gum having a great resemblance to gum Tragacanth, yielded by the trunk of the *Cochlospermum gossypium*, a tree common in the Arracan mountains, in Bundlecund, and other places. This gum is considered useless in the arts, and in medicine it is used by native practitioners as a demulcent and emollient.—*Faulkner.* The true,

(4769) KUTIRA GUM, is the produce of Cochlospermum gossypium or yellow-flowered Cotton tree; but under the same name and of very similar properties, is often sold the gum of several species of sterculia, (Bulea) of Bombax pentandrum, Huttian ka goond &c. &c. See KOTHEELA.

(4770) KUVEAMA, the Tamil name of a Ceylon tree which is remarkably heavy and strong. It grows to about two and a half or three feet in diameter, and is curved in its growth. It is used in the frames of native vessels: it produces a fruit which is of no use.—*Edye. Ceylon.*

(4771) KYABOCA-WOOD OR AMBOYNA-WOOD, is imported from Singapore, appears to be the excrescence or burr of some large tree, it is sawn off in slabs from 2 to 4 feet long, 4 to 24 inches wide, and 2 to 8 inches thick; it resembles the burr of the yew-tree, is tolerably hard, and full of small curls and knots, the colour is from orange to chesnut-brown, or sometimes red brown. It is a very ornamental wood, and is much esteemed in China and India, where it is made into small boxes and writing desks, and other ornamental works, the same as by ourselves. The Kiabooka is said by Prof. Reinwardt, of Leyden, to be the burr of the *Pterospermum indicum*; by others that of *Pterocarpus draco*, from the Moluccas, the island of Borneo, Amboyna &c. The native name appears, from the specimen of Mr. Witson Saunders to be "*Serioulcut*," the wood itself is of the same colour as the burr, or rather lighter, and in grain resembles plain Mahogany. "The root of the cocoa-nut tree says Colonel Lloyd is so similar, when dry and seasoned, to the 'bird's-eye' part of the wood here termed kyabooca, that I can perceive no difference, the cocoa has a tortuous and silky fracture, almost like indurated asbestos."—*Col. G. A. Lloyd.* The comparison of the palm wood with the kiabooca, renders the question uncertain, as amongst the multitudes of ordinary curly woody fibres, that one cannot account for in a palm there are a few places with soft friable matter much resembling it.—*Holtiz.* At the Madras Exhibition of 1855, a slab of Kyabooca wood, imported from Singapore was exhibited by J. Sanderson, Esq. A small portion was polished, and showed well the highly ornamental appearance of the timber in its marking. The specimen exhibited the very knotty character and curly fibres of the wood, from which pieces of even a foot square free from flaws, can rarely be obtained. The Botanical name of the tree has not yet been determined with certainty, although it is generally believed to be "*Pterospermum indicum*."—*M. E. J. R.*

(4772) KYANAN. On the low lands near the sea-coast of Tenasserim, there is a large tree of which canoes are occasionally made, that is much used for sandals. The wood is red; but turns black on being anointed with petroleum. I have never seen the tree either in flower, or fruit; but it has pinnate leaves, with two pairs of oval leathery leaflets, and is, I imagine, a leguminous tree.—*Mason.*

(4773) KYDIA, a genus of plants occurring

in Southern Asia. Several of the family it belongs to, abound in mucilage, and as a Guazuma is employed in South America in clarifying sugar, so a Kydia is in India. Dr. Wight in Icones, gives Kydia calycina, 879-880; *fraterna*, 879-880; Kydia *pulverulenta*, 881; Roxburghiana, 881.

(4774) KYDIA CALYCINA.

Bokemaiza, Burm.

A middle sized tree, pretty common along the Western Ghauts. Hort. Gard. 69. *Kydia calycina* is plentiful throughout the Forests, more especially in the Pegu and Tounghoo districts. The small saplings are used, from their great strength and elasticity, by the natives, for making banghy sticks, but it is large enough to afford timber of three or four feet girth. Wood, white-colored, adapted to every purpose of house-building.—*McClelland.*

(4775) KYLLINGIA MONOCEPHALA. One headed Killingia, common at Ajmere in low grounds. The root is sweet-scented, used and named as Zedoary: "nirbishee."—*Genl. Med. Top. p.* 174.

L.

(4776) LABIATÆ, Dr. Royle very appropriately sums up his account of this family, by stating that many which are indigenous in the Himalayas, continue to be imported from the Red Sea, to be prescribed at the foot of the mountains where the fresh and genuine articles may be had in any quantity. Dr. Royle especially recommends the introduction of the peppermint, with the essential oil of which the natives are well acquainted, from its common use in Cholera. He informs us that species of Anisomeles, Dyospita, Elschotzia and Pogostemon are used as substitutes, for their European allies. The only plant of this family much cultivated in India is the Dracocephalum Royleanum, or Balungoo, the seeds of which, *Tukm balungoo*, are very generally used in India for the preparation of mucilaginous drinks.—*Royle, p.* 303;—*O'Sh. p.* 492.

(4777) LABLAB, a name, it is said, of Egyptian origin, which has been adopted by botanists to designate a genus of Papilionaceous *Leguminosæ* of the tribe *Phaseoleæ*. This genus, like *Dolichos*, from which it has been separated, is a twisting climber, with leaves composed of three large leaflets. The flowers are in racemes, and either white or purple-coloured. The legumes are large, scimitar-shaped, flat, and compressed, tubercularly muricated along the sutures, and having the seeds separated from one another by transverse partitions. It is on account of these seeds and legumes that the species are valued and cultivated in hot countries such as India, Egypt, and the West India Islands, as well as in China. In India *L. vulgaris* and *L. cultratus* are chiefly cultivated in the rainy season in gardens, and may be considered the analogues of the French and kidney beans of European gardens. —*Eng. Cyc.*

(4778) LABLAB VULGARIS. Sayme ke Pullie Lat. Dolichos Lablab Native Bean, red.

Averay kaya, also Tatta pyre, Tam.

(4779) LABLAB VULGARIS, *var* FLORE RUBRO. Dolihos.

Segapoo Averay kai, Tam. | Yerra Chickoodi kaia, Tel.
Laul saym ke pullie, Duk.

Lablab has a compressed scimitar-shaped pod, rough, with tubercles at the sutures, and furnished with transverse imperfect cellular partitions, and ovate seeds with a fungous, callous, linear scar. *Lablab vulgaris*, the old *Dolichos Lablab*, is a common plant in the hedges in many parts of India, whence it has travelled into the tropical parts of America. It is a smooth perennial with showy white or purple flowers, and large horizontal pods, containing from three to four seeds. It has a heavy disagreeable bug-like smell, prefers a rich black soil that cannot be flooded by rains, and produces a coarse but wholesome pulse, much eaten by the lower classes in India.—*Eng. Cyc.* This bean is sown in the fields like all others in rows, and are eaten both boiled or put into curries.—*Riddell.* This valuable legume when young is eaten pod and all, when full grown the seeds only are used. It is about five inches long and has got its names from the reddish colour of its edges.—*Ainslie, p.* 244. Burmese and Karens grow several varieties of one or two species of lablab, which occupy the place of kidney beans in Europe.—*Mason.* The pods of this plant are used as a substitute for French beans, the beans in curries; commonly cultivated in gardens, of easy growth, a pandal is required for its support.—*Jaffrey.*

(4780) LABRAX. (Cuvier), a genus of Fishes of the section *Acanthopterygii* and family *Percidæ*. The fishes of this genus are closely allied to the true Perches, but may be distinguished by the opercular bones being covered with scales, the absence of denticulations on the suborbital and interopercular bones, the operculum being terminated by two spines, and likewise by the tongue being almost entirely covered with minute and closely-set teeth. There are two dorsal fins. —*Eng. Cyc.*

(4781) LAC.

Laak. Arab.	Ambaloo, Mal.
Gomlac, Dut.	Lacca em paos, Port.
Lakada, Cyng.	Laka, Rus.
Lacque, Fr.	Laksha, Sans.
Lack, Ger.	Goma-laca, Sp.
Lakh, Guz. Hind.	Komburruki, Tam.
Lacca, It.	Commoleka, Tel.
Balo, Jav.	Khjeijk, Burm.

It is a substance obtained from incrustations made by an insect (coccus lacca), similar to the cochineal, (coccus cacti) on the branches and twigs of many trees in India, as *Vatica laccifera*, *Croton laccifera*, *Butea frondosa*, *Inga dulcis*, *Feronia elephantum*, *Erythrina indica*, *Schleichera trijuga*, (coosumb tree,) &c. The lac is formed by the insect into cells, somewhat resembling a honey-comb, in which the insect is generally found entire, and owing to whose presence, stick-lac yields by proper treatment a red dye, nearly if not quite as bright, as that obtained from Cochineal, and more permanent. Lac is found encircling the branches of these trees in the form of a tube ($\frac{1}{2}$ inch to one inch in diameter) the broken branches with encrustations at various distances is called in commerce *stick-lac* which ought to be semitransparent. The coloring matter exhibited by grinding stick-lac, and then treating it with water, constitutes *seed-lac*. At the Madras Exhibition of 1855, the crude stick-lac attached to branches of various trees as abovementioned was exhibited from 16 localities extending from Kamptee to Trivandrum. The resin is abundant in the jungles of S. India, but is not much collected for commercial purposes, although always procurable in the bazars; the best lac is produced upon the *Schleichera triguga*, which abounds in the central provinces, and yields the colouring matter twice a year.—*M. E. J. R.* *Coccus Lacca.* "When the females of this Coccus have fixed themselves to a part of the branch of the trees on which they feed (*Ficus religiosa* and *F. Indica*, *Butea frondosa*, and *Zizyphus jujuab*), a pellucid and glutinous substance begins to exude from the margins of the body, and in the end covers the whole insect with a cell of this substance, which, when hardened by exposure to the air becomes lac. So numerous are these insects, and so closely crowded together, that they often entirely cover a branch; and the groups take different shapes, as squares, hexagons, &c. according to the space left round the insect when first it began to form its cell. Under these cells the females deposit their eggs, which after a certain period are hatched, and the young ones eat their way out." (Kirby and Spence, Vol. IV, p. 124).—*Eng. Cyc. Vol.* II, *p.* 44. In Bengal, Lac is chiefly produced in the forests of Sylhet and Burdwan; it is also procurable in the Deccan; but Siam and Pegu afford the largest supplies.—*Faulkner.* At the Madras Exhibition of 1857, Lac was exhibited from the Ficus elastica, Butea Frondosa and Zizyphus jejuba.—*Madras Exhibition of* 1857. This substance, which is improperly called a gum, is found in great abundance on the Croton laccifera (growing near Columbo), on the island of Ceylon, it is also an article of commerce from Siam and Pegu. The Abbe Rochon informs us that Gum Lac is brought from Quan-an-ton in the province of Quei-chu in China, but of a quality greatly inferior to that of Bengal. The Vyteans prescribe Komburruk in old and obstinate bowel complaints, when the habit has been much reduced; they also (when mixed with Gingelie oil) use it has an external application for the head,in cases in which the patient is debilitated from long continued fever. The stick-lac from Pegu is, perhaps, the finest in the world, preferable even to that of Bengal. See *Oriental Repertory.* —*Vol. 2d*, *page* 580. Mr. W. Francklin in his Tracts, Political,Geographical, Commercial on the dominions of Ava (page 71), tells us, that Charong is the name given in the Burmah country,to a kind of black lac which is extracted from a large tree; one or two plants of which were brought to Calcutta by Captain Cox. He adds that the lac was in general use amongst the Natives for their lacquered ware.—*Ains. Mat. Med. p.* 23. The jungle at Taldungah consists chiefly of thorny bushes, Jujube of two species, an *Acacia* and *Butea frondosa*, the twigs of the latter often covered with lurid red tears of Lac, which is there collected in abundance. As it occurs on the plants and is collected by the natives it is called Stick-lac, but after preparation Shell-lac. In Mirzapore, a species of *Celtis* yields it, and the Peepul very commonly in various parts of India. The elaboration of this dye, whether by the same species of insect, or by many from plants so widely different in habit and characters is a very curious fact; since none have red juice, but some have milky and others limpid.—*Hooker Him. Jour. Vol.* I. *p.* 9. According to Tomlinson, Lac is a resinous substance found on several different kinds of trees in the East Indies, and produced by the punctures of an insect (*coccus lacca*), and by its formation of the exuding juice into cells for its eggs. These adhere to the branches in grains, completely encrusting them, and are either imported in that form, and called *stick-lac*, or the grains are gathered from the branches, their colouring matter extracted, and formed into flat cakes, still preserving the granular appearance, and called *seed-lac*, or the seed-lac is melted up into masses, and called *lump-lac*. Finally there is *shell-lac*, which is seed-lac further purified by being put in bags of fine linen, and melted over a charcoal fire until it passes through them. The bags are squeezed, and passed over a smooth surface of wood, on which the lac is deposited in thin layers. If pure, this kind of lac will take fire on a hot iron, and burn with a powerful smell. The heat of a ship's hold will sometimes run it into a solid mass, and

thus diminish its value. The chief consumption of lac in Europe is for the manufacture of sealing-wax and varnishes. In India the inferior kind is made into bangles or armlets for women of the lower classes, the superior is fashioned into rings, beads, and other trinkets; and to fit it for such purposes, the natives purify it by melting in the manner above described. When the lac begins to exude, it is scraped off, and the bags are twisted or wrung by means of cross-sticks at their ends, to force out the melted contents. The natives of India make a good varnish of lac, coloured with cinnabar or some other pigment, with which they varnish boxes, cabinets, and other articles. Coloured varnishes of this description are much used in the adornment of their religious houses. They also employ lac as a dye. By pouring warm water on stick-lac a crimson colouring matter is obtained, which is made into square cakes for sale, and called *lac dye*, *lac lake*, or *cake lake*. These cakes when broken are dark-coloured, shining, and compact, but when scraped they yield a bright red powder approaching carmine. A mixture of lac, alum, and tamarind-water is the native dye for silk or cotton cloth of a crimson colour. The Indian lapidaries make use of lac as a vehicle for retaining the hard powders used in cutting and polishing gems. The Indian corundum wheels are described under EMERY. The dye above referred to, and which constitutes much of the value of lac, is due to the insect which makes the cells, and which is of the same family as the cochineal insect. The parent lac insect, after laying her eggs, becomes a mere lifeless bag, of an oval shape, containing a small quantity of a beautiful red liquid. The young insects feed on this liquid, and their bodies assume the same hue, so that the branch which bears them appears to be covered with red powder. The cells of gum-lac which shelter them are more or less deeply tinged with the same colour. The best time for gathering stick-lac, so as to secure the colouring matter, is before the insects have made their escape. Previous to the discovery of the true cochineal, the colouring matter of the lac insect was universally employed for dyeing red. The crimsons of Greece and Rome, and the imperishable reds of the Brussels and Flemish schools, were obtained from this source. The best quality of stick-lac is obtained from Siam; the twigs being frequently encrusted all round to the depth of a quarter of an inch, while sometimes a great accumulation takes place on one spot, that of Assam ranks next: the stick-lac of Bengal is inferior to these, being scanty and irregular in its coating of resinous matter. So abundant is the supply of lac among the uncultivated mountains of India, that it is asserted a consumption ten times greater than at present might be readily supplied. The accumulation of insects is so great, that the trees, often a species of *ficus*, on which they live, are exhausted and injured by this vermin. After the dye is extracted, the gum-lac still requires much purification before it can be used for the more delicate varnishes. It was long a desideratum to render lac colourless, its dark brown hue being a drawback to its use as a spirit varnish. A premium of thirty guineas and a gold medal were offered by the Society of Arts for "a varnish made from shell or seed lac, equally hard, and as fit for use in the arts," as that prepared from any other substance. These were claimed by two persons, Mr. Field and Mr. Luning; and as both their processes were found to answer the desired end, a premium of twenty guineas was awarded to each. See VARNISHES.—*Tomlinson.*

(4782) LACE.

Kanten, DUT.	Merletti, Pizzi, IT.
Dentelle, FR.	Krushewo, RUS.
Spitzen, GER.	Encajes, SP.

A plain or ornamental net work, tastefully composed of many fine threads of gold, silver, flax, and cotton, interwoven. There are many varieties of lace, each bearing a distinct name, and having peculiar qualities.—*Faulkner.* At the Madras Exhibition of 1855, some very fine thread lace was contributed by the Edeyengoody Mission School Tinnevelly, and by the Nagercoil Mission School, Travancore, so nearly equal in merit that a second class medal was awarded for each. The patterns of both were varied and tasteful, but the prices above those of European lace. The Cochin Local Committee exhibited some very creditable specimens of lace insertion and edging. Some excellent specimens of *Gold Lace, Cord Sashes and Sword Knots* were exhibited by the Madras Local Committee, deserving of honorable mention.—*M. E. J. R.* Lace is a term unlikely applied to two very distinct arts, one consisting of gold and silver wire, or even silk thread, woven into ribands for embroidering hats and uniforms. The other is the well-known transparent network, in which the threads of the weft are twisted round those of the warp; it may be made of silk, flax or cotton, or even of gold and silver thread, and has usually a pattern worked upon it, either during the process of making the lace, or with a needle, after this has been completed. Though much lace is now made by machinery, the highly esteemed genuine articles is made by hand; and, therefore, may fitly commence the series of arts which depend chiefly on manual dexterity. Lace knitting is considered to be a German invention; but lace worked by the needle is of far older date, and was probably an Eastern invention, though it does not appear to have been known or practised in India. Lace however is enumerated by General Cullen as being made in the territories of the Rajah of Travancore; and the

Madras Central Committee, in their final report, state, that "the lace of Nagercoil, which, though knit by natives of the country, was declared equal to the best French lace." A few of the European residents are already aware of the superior quality of "the lace, and use it, but its beauty is well deserving of being more generally made known than it at present is." The lace, when seen at the Great Exhibition, was much admired, and some said that it must have been made in France. But the doubt may easily be resolved, and advantage would result to all parties, by giving orders for some of this lace to the native workers in Travancore. Samples of six different kinds were sent. Gold and silver blond lace are both excellent of their kinds, but as the demand is limited, and fashion changeable, they might not always command a sale. But the broad black lace on wire-ground, and the broad white and fine lace on Brussels ground, and of the nature of Bedfordshire lace, are highly approved of by the best authorities. The broad being thought worth four shillings, and the narrow worth two shillings a-yard.—*Royle, Arts &c. of India, p.* 503.

(4783) LACERTA SCINCUS. Linn. Is still used by the Eastern doctors. It has been recommended in leprosy.—*Thirty five years in the East, by Dr. Honig. p.* 342.

(4784) LACERTIADÆ OR LACERTIANS. Under the family name Lacertians, Cuvier arranged—1st. The Monitors and their subdivisions, namely, the Monitors properly so called, including the Ouarans of the Arabs (*Varanus*), &c.; the Dragons (*Crocodilurus* of Spix, *Ada* of Gray), and the Sauvegardes (*Monitor* of Fitzinger and Ameiva). 2nd. The Lizards properly so called. The second group comprises, according to Cuvier, the genera *Lacerta*, *Algyra*, and *Tachydromus*.—*Eng. Cyc.*

(4785) LAC DYE. LAC LAKE. Consists of the colouring matter extracted from the stick lac. It is met with in small square cakes, similar to indigo. They are used as red dyes for some purposes, instead of Cochineal. Lac dye is largely manufactured in Bengal, whence it is exported to England. A sample of this dye was exhibited at the Madras Exhibition of 1855 by Mr. Flynn, who supplies the following information. "Lac Lake was prepared by boiling coarsely powdered Rangoon stick lac in several portions of water, until it ceased to yield any colouring matter; a small quantity of Alum was then added to the filtered solution, after a few minutes, a small quantity of Liqr. Potassæ was used to throw down the *Alumina* with the colouring matter, the fluid at the same time being constantly agitated. The precipitate was allowed to settle for a day, the fluid then drawn off and the sediment pressed into cakes and dried in the shade." The Jury awarded Mr. Flynn honorable mention.—*M. E. J. R.*

(4786) LACKER. A varnish either for wood or for brass, made with shell-lac and spirits of wine. That for wood called *hardwood* lacker, may be in the proportion of 2 lbs. of lac to the gallon. Another recipe is 1 lb. of seed-lac and 1 lb. of white rosin to a gallon of spirits of wine. For brass the proportions are ½ lb. of pale shell-lac to 1 gallon of spirit. It should be made without heat, but simply by agitation for five or six hours. It should then be left until the thicker portions have subsided, when the clear lacker must be poured off, or if not sufficiently clear, it must be filtered through paper. It darkens by exposure to light, so that paper should be pasted round the bottle to exclude it. A pale yellow lacker may be prepared from 1 oz. of gamboge and 2 oz. of Cape aloes, powdered and mixed with 1 lb. of shell lac. For a full yellow, ½ lb. of turmeric and 2 oz. of gamboge: for a red lacker, ½ lb. of dragon's blood and 1 lb. of annotto. The colour, however, is modified by that of the lac employed. Lackers may also be coloured by dissolving the colouring matters in spirits of wine, and adding the proper proportions of these to the pale lacker, according to the tint required. Mr. A. Ross prepares lacker with 4 oz. of shell-lac and ¼ oz. of gamboge, dissolved by agitation in 24 ounces of pyro-acetic ether. The clear liquor is decanted, and when required for use is mixed with eight times its volume of spirits of wine. Hardwood lacker is applied nearly in the same manner as FRENCH POLISH. In lackering brass, the work must be cleansed from grease and oil, and if convenient, heated to the temperature of boiling water, when the spirit evaporates, and the varnish attaches itself more firmly to the metal, producing a brilliant effect. If heat cannot be applied, the air should be dry and warm. The lackering should follow immediately after the work is polished, otherwise it will become tarnished, and prevent the lacker from adhering. To prevent this tarnish, the work may be smeared over with oil, or kept under the surface of pure water, or wrapped closely up in cloths. Before lackering, the oil must be carefully cleaned of with *moslings*, and afterwards with whitening applied with a rag or a brush. In brasswork factories, a *lackering-stove*, with a broad, flat top, is used for holding the articles which are to be heated preparatory to lackering; or a metal plate, supported by four legs like a table, and heated by a ring of gas-jets below, may be used. Brass tubes may be heated for lackering by being filled with boiling water, the ends being stopped with corks. In lackering the heads of a large number of small screws, they may be inserted in a piece of card, and heated over a charcoal fire or a gas flame, and the whole be lackered at one process. In thin circular works, the friction of polishing gives the heat required for the process. The lacker must be laid on quickly and uniformly by means of a camel's-hair brush; and as soon as one

coat is applied, another must be put on, heat being used between the two coats if necessary. Circular works may be lackered on a lathe.—*Tomlinson.* The word *lacquer* is evidently derived from the Indian name *lac* or *look*. The name occurs in Avicenna, who mentions it, as described by some, as the gum of a tree like the myrtle, and by others that it is a substance like to, and having some of the properties of amber. It is mentioned in many Indian works, and is apparently alluded to by Ctesias. This substance is used for a variety of purposes in India, and it is the common material for uniting things together, as gum and glue are in Europe. viz. Toys of various kinds, lac chains gilt, and lac grindstones, were shown. The term lacquer is applied to laying on or covering with a preparation of lac; but two different processes are usually confounded under this term. The one prevailing in Burma and the southern parts of the Indian Peninsula was well known to Dampier, in 1638, as he says, "The lac of Tonquin is a sort of gummy juice which drains out of the bodies or limbs of trees," and that "the articles lackered are cabinets, desks, &c." Some chemical change, no doubt, takes place on exposure of these juices to the air. This kind of lacquered ware was much appreciated in the last century, and was imported chiefly from China; much, however, was always prepared in Burmah, though that of Japan was always considered superior to any other, and of which many fine specimens may still be seen in large folding screens, &c. Both these and the lacquer of Burma are prepared only from the juice of a family of plants (the *Terebinthaceæ*), the same as that to which the marking nut and sumach belong. The chief expense of the manufacture arises from the care with which successive layers of varnish must be laid on. Various specimens of boxes have been sent from Moulmein and from Singapore, some showing different stages of the process. Another kind of lacquer-work is rather of the nature of papier-mache, covered with one or more layers of lac varnish. This is the case with the lacquered boxes from Cashmere and Lahore, so remarkable for the beauty and elegance of their patterns.—*Royle Arts &c. of India, page* 486. At the Madras Exhibition of 1855, a series of lacware from Hyderabad consisting of bracelets, chains, neck ornaments, pincushions, purses, and other ornaments were exhibited through Dr. Smith, excellent of their kind, and well finished. Some large and interesting specimens of this manufacture contributed from Kurnool, consisted of Charpoys, Trays, an Almirah and several boxes, and exhibited considerable proficiency in the execution and arrangement of the patterns, but too great a sameness of color with a preponderance of yellow. The joinery also admits of much improvement. *M.E.J.R.* In China, lackered ware was formerly exported in considerable quantities, but partly owing to the liability to injury on the homeward passage, and being superseded abroad by other things more substantial, the exportation has dwindled to a mere trifle. Such articles as are exported consist of those which have always been in request, as fans, waiters, boxes, teaboards, tea-caddies, teapoys &c. The patterns worked on them affect their sale, and the least mark spoils the varnish. The best kind of lackered ware comes from Japan, but it is difficult to be obtained in China. *Com. Des.* The beauty of the lacquered-ware of China owes its lustrous coloring to a composition of lampblack and the clarified juice obtained from a species of sumach, called *Rhus vernix* or *Vernicia.* Wood oils are obtained from other plants of the same family, and the different qualities of lacquered-ware are owing to the use of these inferior ingredients. The real varnish tree is described by De Guignes as resembling the ash in its foliage and bark, it is about fifteen feet in height, and furnishes the sap when seven years old, which is carefully collected from incisions in the trunk opened in the summer nights. The body of the ware is wood partially smoothed, or pasteboard, upon which two or three coats of a composition of lime, paper, and gum are first laid and thoroughly dried and rubbed. The surface of the wood is also hardened by rubbing coarse clay upon it, and afterwards scraping it off when dry. Two coatings of lampblack and wood oil, or in the finer articles, of lampblack and varnish, are laid upon the prepared wood, and after drying, the clear varnish is brushed on, one coating after another, with the utmost care, in close and darkended rooms, allowing it to dry well between the several coats. The articles are then laid by to be painted and gilded according to the fancy of customers, after which a last coating is given them. The varnish is brought to market in brownish cakes, and reduced to its proper fluidity by boiling; it is applied to many purposes of both a varnish and paint, when it is commonly mixed with a red or brown color. A beautiful fabric of lacquered ware is made by inlaying the nacre of fresh and saltwater shells in a rough mosaic of flowers, animals &c. into the composition, and then varnishing it. Another kind, highly prized by the Chinese, is made by covering the wood with a coating of red varnish three or four lines in thickness, and then carving figures upon it in relief. The great labor necessary to produce this ware renders it expensive. A common substitute for the true varnish is the oils of the Dryandra, Jatropha, Croton, and other members of the Euphorbiaceous family, expressed from their seeds by a variety of simple machines, consisting for the most part of different applications of power to cylinders and pestles by which the seeds are pressed or pounded. The oil, after pressing, according to De Guignes, is boiled with Spanish white

in the proportion of one ounce to half a pound of oil; as it begins to thicken, it is taken off and poured into close vessels. It dissolves in turpentine, and is used as a varnish, either clear or mixed with different colors; it defends woodwork from injury for a long time, and forms a good painter's oil. Boiled with iron rust, it forms a reddish brown varnish. In order to prevent its penetrating into the wood when used clear, and to increase the lustre, a priming of lime and hog's blood simmered together into a paste is previously laid on.—*Williams' Middle Kingdom, Vol.* II, *p.* 121.

(4787) LACTUCA, a genus of Plants belonging to the natural order *Compositæ*, the suborder *Ligulifloræ*, the tribe *Cichoraceæ*, and the sub-tribe *Lactuceæ* of De Candolle. It has a cylindrical imbricated involucre, with the scales membranous at the margin, and few-flowered; the receptacle naked; the achenium compressed, wingless, with a long filiform beak; the pappus hair-like in several rows. *L. virosa*, Acrid Lettuce, has leaves with a prickly keel, horizontal, oblong, auricled, and clasping mucronate, dentate or sinuated, the beak white, equalling the fruit, which is black. This plant is found on hedges, old walls, and the skirts of fields throughout Europe. It yields a milky juice, which, when procured and dried, has the name Lactucaricum. This substance is also procured from the Garden Lettuce (*L. sativa*), and in the 'London Pharmacopœia' the *L. sativa* is the only plant recognized for supplying this substance.—*Eng. Cyc.*

(4788) LACTUCA SATIVA. Garden or Roman lettuce.

Kahoo. Hind.

A well known garden vegetable, inodorous, of scarcely sensible taste, or slightly bitter: at the flowering time it contains a milky juice, which has acquired some celebrity under the name of Lactucarium, or Thridace.—*O'Shaughnessy. page* 406.

(4789) LADUNUM or LABDANUM. Cistus creticus. Lin.

Laden, Arab. | Ladanum, Lat.
Ciste, Ladenifere, Fr. |

This resinous substance which was considered by some of our old writers cephalic, pectoral and nervine, is now only used by us in the preparation of certain plasters. It is not unknown to the Mahomedan medical Practitioners of lower India, and has a place in the Materia Medica of the Arabians amongst their Munzigat (Supparantia).—*Ains., Mat. Med. p.* 23. Ladanum, is sometimes written *Labdanum*, but incorrectly as it is the Λήδανον of the Greeks, and the Ladun of the Arabs. It is first mentioned by Herodotus (iii. 112) as procured in Arabia, and used by the Arabs for fumigation. The word is not Greek, but an Arabic word with a Greek termination; the Greeks also used the word Λήδος to indicate the shrub which produced the Ladanum. This gum-resin is produced by several species of *Cistus*, the Κισσος, of Dioscorides, though the name and description are often confounded with those of the Κίσσος, or *Hedera*. *C. ladaniferus*, *C Creticus*, and *C. Ledon*, Lam., are usually mentioned as the species which are indigenous in the Grecian Islands, in Spain, Italy, and the south of France. That obtained from the Levant is the most celebrated. The juice exudes upon the leaves and branches of these shrubs and is collected, according to Tournefort, by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant; and as the juice adheres to the thongs, it is afterwards separated. Ladanum is also described by Dioscorides as being collected from the beards of goats which had been feeding on the leaves of *Cistus*. (Compare Herodot. iii. 1112.) It is now seldom employed for any purpose, as it is with difficulty obtained of a sufficient degree of purity from the adulterations to which it is subjected; one analysis yielding 72 parts of ferruginous sand, and another 86 of resin, out of 100 parts. The purest kind, seen only in the places where it is produced, is described as blackish, homogeneous, and tenaceous; easily softening under the fingers, and even sticking to them; having a grayish fracture, which however becomes black by exposure to the air; rather a bitter taste, and a very agreeable smell from the presence of a volatile oil. It was formerly employed as a stimulant, more recently as an expectorant, and is esteemed even in the present day by the Turks as a perfume, and used for fumigation.—*Eng. Cyc.*

(4790) LAGENARIA (from 'lagena,' a bottle), a genus of Plants belonging to the natural order *Cucurbitaceæ*. The flowers are monœcious, the calyx campanulate, with subulate segments shorter than the tube. The corolla is white, with obovate petals spreading below the edge of the calyx. It has five triadelphous stamens, the fifth one distinct; three subsessile granulated stigmas, obovate compressed seeds, tumid at the margin, 2-lobed at the apex.—*Eng. Cyc.*

(4791) LAGENARIA IDOLATRICA, is held in great veneration by the Hindoos in their religious ceremonies. (Don, *Dichlamydeous Plants*; Lindley, *Flora Medica.*)—*Eng. Cyc.*

(4792) LAGENARIA PIPO.

Pooshnee-kai, Tam.

The Pumpkin, similar to the above, much used by the natives.—*Jaffrey.*

(4793) LAGENARIA VULGARIS. *Syn.* Cucurbita lagenaria. Bottle gourd. East Indies.

Soriaic-kai, Tam.

Belaschora (Rheede,) *Toombee*, (Royle,)—the Gourd of this variety is used for making the stringed musical instrument called the *Sitar*.—*O'Shaughnessy. L. vulgaris*, the common Bottle-Gourd, is a musky-scented plant, and clothed with a soft down. It has a climbing stem, with tendrils from 3 to 4-cleft. The flowers are stellated, spreading, and in clusters; the fruit in shape like a bottle, when ripe of a pale-yellow colour, sometimes six feet in length. When dried it becomes hard, and is used to contain water; it is then of a pale bay colour. In its wild state this plant produces a poisonous fruit, and Dr. Royle states that a very intelligent native doctor informed him that cases of poisoning have occurred from eating the bitter pulp in the district where it grows. Some sailors also are said to have died from drinking beer that had been standing in a flask made from one of those gourds. These injurious effects seem however to be removed by cooking, for Don says that the poor people among the Arabians eat it boiled with vinegar, or fill the shells with rice and meat, and so make a kind of pudding of it. The pulp of the fruit is often employed in poultices; it is bitter and purgative, and may be used instead of colocynth. This species grows abundantly in Egypt and Arabia; the Arabians call it Charrah; it thrives wherever the mountains are covered with a fit soil. There are three other species enumerated by Don growing in Guinea and the East Indies.—*Eng. Cyc.* The Lagenaria Vulgaris. or the Bottle gourd is commonly cultivated by the natives, to whom it is of some importance as food; of easy culture, seldom eaten by Europeans, it being very coarse.—*Jaffrey.* In Tenasserim, the bottle gourd grows luxuriantly, and several varieties may be seen about the Indian cabins.—*Mason.*

(4794) LAGERSTRŒMIA, a genus of Plants of the natural family of *Lythraceæ*, which extends from the Malayan Archipelago into China and Japan, as well as along the foot of the Himalayan Mountains to the northern parts of India. The genus was named by Linnæus in honour of Lagerstrœm, who was director of the Swedish East India Company and imported many interesting plants from India and Chiua. The species are few in number, but most of them highly ornamental in nature. *L. Reginæ* especially forms a small tree and is conspicuous from its large rose-coloured flowers, of which the petals, standing out on rather long claws, more fully display the varied outline of its undulated limp. The bark and leaves are accounted purgative and hydragogue, the seeds narcotic. *L. Indica and L. parviflora* are small and shrub-like and suited to our hot-houses, but all require moisture in the season of flowering.—*Eng. Cyc.* Speaking of this genus, as they occur iu China, Mr. Williams remarks that few trees in any country present a more elegant appearance, when in full flower.—*Williams' Middle Kingdom, p.* 285. Mr. Fortune speaking of Hongkong says, the Botany of the island possesses a considerable degree of interest, at least would have done so some years ago, when the plants indigenous to it were less known than they now are. By far the most beautiful plants met with on the low ground, are the different species of Lagerstrœmia. There are two or three varieties, having red, white, and purple flowers, and in the summer months when they are in bloom, they are quite hawthorns of China; surpassing in their gorgeous flowers even that beautiful family. I have generally met with them in a wild state, very near the sea shore. A little higher up we find the beautiful Ixora coccinea flowering in profusion in the clefts of the rocks, and its scarlet heads of bloom under the Hong-kong sun are of the most dazzling brightness. The ravines are crowded with ferns and creeping shrubs of different kinds, not however of much interest to the lover of ornamental flowering plants. Here, however, under the ever-dripping rocks, we find the beautiful Chirita sinensis, a plant with elegant foxglove lilac flowers, which I sent to the Horticultural Society soon after I arrived in China, and which is now to be found in many of the gardens of England. —*Fortune's Wandering, page* 20.

(4795) LAGERSTRŒMIA. SMALL LAGERSTŒMIA. The Tavoy forests are adorned with a smaller species of largerstrœmia than the L. Indica but the flowers are equally elegant and quite as large.—*Mason.*

(4796) LAGERSTRŒMIA ALBA. LAGERSTRŒMIA INDICA.

Henna or Telinga, CHINA.

This is the white flowering species of the China mendie. A common shrub in gardens, and used for border hedges, it bears a small reddish flower and grows easily from cuttings at the commencement and during the rains.—*Riddell.*

(4797) LAGERSRŒMIA GRANDIFLORA. In the Terai, east of Siligoree, *Bombax, Erythrina*, and the *Duabanga* (*Lagerstrœmia grandiflora*), were found by Dr. Hooker in full flower, and with the profusion of *Bauhinia*, rendered the tree-jungle gay; the two former are leafless when flowering. The Duabanga is the pride of these forests. Its trunk, from eight to fifteen feet in girth, is generally forked from the base, and the long pendulous branches which clothe the trunk for 100 feet, are thickly leafy, and terminated by racemes of immense white flowers, which, especially when in bud, smell most disagreeably of assafœtida.—*Hooker Him. Jour. Vol.* I. *p.* 401..

(4798) LAGERSTRŒMIA INDICA. Indian Lagerstrœmia Tsjinkin (Rumph.) This is a small pretty shrub, common in gardens in Maulmain, and of easy cultivation.—*Mason.* Tsjinking is the name given, in Rumphius, to one of the most

beautiful flowers in our Indian gardens, which however, does not appear to be a native of India, having no proper Tamool appellation, but is sometimes called Cheena poo by the gardeners. This shrub grows to the height of seven or eight feet; the flowers hang in bunches at the extremity of the branches, and are of a beautiful lilac colour.—*Ains. Mat. Med. p.* 164.

(4799) LAGERSTRŒMIA LANCEOLATA.

Bodah or Bondaga, Hind.

An erect tree with oblong lanceolate leaves, flowers small, white, appearing in April and May, the whole of the species may be propagated by seed or cuttings in any garden soil.—*Riddell.*

(4800) LAGERSTRÆMIA MICROCARPA. Ben Teak. Icon. 109.

Venteak, yen bugum, Eng.	Cutchay cuttay marum or
Benteak, Ventakoo, Can.	Ven takoo marum, Tam.

A tree of large size with a long straight stem, the timber is of ordinary character, easily worked and suited for purposes where strength and beauty are not required.—*M. E.* This tree attains a large size and, for common purposes, where timber of inferior quality is sufficient, is very useful, being easily worked. Tested by the scale it only bore 290 lbs. on a second trial however it sustained 374 lbs. Were it stronger and more durable, the length and straightness of the stem would adapt it for spars. —*Wight.* Common in Wynaad and on the Western Ghauts: wood prized for making coffee cases.—*McIvor.*

(4801) LAGERSTRŒMIA PYMMAH.

Pymmah, Burm.

A common and valuable timber, found generally all over the Pegu country. It ceases however a little below Tounghoo and Prome, so that at those places it cannot be made available for building purposes; but at all the lower stations from Prome and Tounghoo downwards, it ought to supersede the use of Teak. Red-colored wood, strong and adapted for house-building.—*McClelland.*

(4802) LAGERSTRŒMIA REGINÆ. Queen Lagerstrœmia. Icon. 413. Roxb. 65.

Cadali pua, Tam.	Stotulari. Sans.
Hort, Mal.	*Ains. Met. Med. p,* 163
Arjano, Beng.	Jarool Adamboe, Rheed

When cultivated in England the queen Lagerstrœmia is a small shrub, but in its native soil it is a large timber tree, and when in flower is one of the most conspicuous trees in the Tenasserim Provinces. A tree in full blossom looks in the morning as if mantled with roses, but the flowers change through the day to a beautiful purple, making it appear at evening, if seen from a short distance, like a bower of English lilacs.—*Mason.* The queen Lagerstrœmia, or jarool, is an abundant timber tree in the Tenasserim Provinces, though very scarce on the Coromandel Coast. The posts of an old wharf at Tavoy which were of this wood, stood erect for twenty or thirty years; but house posts often decay in the ground in a much shorter period. It is considered a valuable timber in ship building. There is a smaller species of lagerstrœmia in the Tenasserim jungles whose wood is inferior, but it is sometimes confounded with the other.—*Mason.* This tree is more celebrated for its large handsome flowers than for its timber, which last however is used for common purposes.—*Riddell.* About 70 miles up the river Soornah, the mountains on the North, which are east of Jynteа rise 4000 feet high in forested ranges like those of Sikkim. Swamps extend from the river to their base, and penetrate their valleys, which are extremely malarious: these forests are frequented by timber-cutters, who fell jarool (*Lagerstræmia* reginæ), a magnificent tree with red wood, which, though soft, is durable under water, and therefore in universal use for boat-building. The toon is also cut, with red sandal wood (*Adenanthera pavonina*); also Nageesa, *Mesua ferrea*, which is highly valued for its weight, strength, and durability: *Aquilaria agallocha*, the eagle-wood, a tree yielding uggur oil, is also much sought for its fragrant wood, which is carried to Silhet and Azmerigunj, where it is broken up and distilled. Neither teak, sissoo, sal, nor other *Dipterocarpi*, are found in these forests.—*Hooker, Him. Jour. Vol.* II. *p.* 327.

(4803) LAGOMYS BADIUS. On entering Tibet, Dr. Hooker found the ground burrowed by innumerable marmots, foxes, and the "Goomchen," or tail-less rat, (*Lagomys badius*), sounding hollow to the tread, and at last becoming so dangerous that he was obliged to dismount and walk.—*Hooker, Him. Jour. Vol.* II. *p.* 156.

(4804) LAGOMYS RUFESCENS, of Gray, is a little quadruped found on the mountains of Afghanistan, and perhaps onward to the Hindu Kosh, but which is very unlikely to inhabit the Indian side of the passes.—*Cal. Rev.*

(4805) LAMB SKINS.

Peaux d ageneaux, Fr.	Pilli agnelline, It.
Lammsfelle, Ger.	Pielles de Corderos, Sp.

Are chiefly used in the glove manufacture. The value of lamb-skins varies according to the fineness, brilliancy, and colour of the wool, the black being most esteemed.—*Faulkner.*

(4806) LAMPS.

Lampe, Ger	Lampadu, Rus.
Lampe, Fr.	Lampara, Sp.
Lucerna, It.	

Are appliances formed of various material and shapes, in which liquid inflammable bodies are burned, for the purpose of producing artificial light. Those in most common use in India are Argand lamps.—*Faulkner.* Lamps are arranged for burning materials which are fluid at or-

dinary temperatures, in order to produce light. Such are the oils. Fats which are solid at common temperatures are usually made into candles. The kind of oil used in different parts of the world for burning in lamps varies with the sources of supply, and these are numerous. In Great Britain, whale oil, boiled from the subcuticular fat of the whale, was long used, and still is to a certain extent, although the general introduction of coal gas has lessened the demand for it. Oils obtained from seeds by pressure are used for artificial illumination in different parts of the world. In Paris, oil of rape-seed and oil of poppy-seed are clarified for lamps by filtration through cotton, wool, and other processes. In the south of France and in Italy an inferior kind of olive-oil is used, as also the oil of *arachis hypogæa*, or earth-nut. In Italy, lamp-oil is expressed from the stones of the grape. In Piedmont, walnut-oil is used; In India, Coconut, castor, gingelly and ground nut oils are in use; on the eastern and southern coasts of the Mediterranean and in China, oil of sesamum seed; and in tropical countries coco-nut oil (which at the temperature of Britain is a white solid like tallow): it is burnt in lamps made of the shell of the coco-nut and of bamboo. Much of the oil used in China is expressed from the seeds of a tree called *Camellia oleifera*, cultivated for the purpose, as is also a shrub, *Croton sebiferum*, from the fruit of which a solid oil is obtained by expression. Seal oil is used by the Esquimaux. The essential oils are too volatile for lamps. Petroleum and naphtha from fossil vegetable matter are used in localities which produce them. Naphtha, the most liquid of the oils, is also prepared by distilling fossil vegetable matter, and is well adapted for burning. In Genoa, the streets are lighted with naphtha from the adjacent territory of Amiano; and some years ago it was obtained by the distillation of pit coal, for the purpose of burning in the street-lamps of London. Alcohol, or spirits of wine, is chiefly used as a source of heat, on account of its clean flame, no soot being deposited.—*Tomlinson.*

(4807) LAMP BLACK.

Noir de fumee, Fr. | Kienruss, Ger.
Nerodi fumo, It.

For the demands of trade, lamp-black is obtained by burning the impurities left in the precipitation of tar and pitch, and collecting the particles carried off, and deposited in the form of soot. The finest kind is procured by collecting the smoke from a lamp, which supplies more oil than can be perfectly consumed. It is used in the arts, particularly in the manufacture of painter's ink.—*Faulkner.*

(4808) LAL CHITRA. Blistering Plumbago. Root of Plumbago rosea.

(7809) LAMINARIA SACCHARINA (spec) is officinal at Lahore and in Cashmere. The fronds are procured from Thibet, where they are reported to grow in a salt lake, but some English physicians maintain, that they are brought from the Caspian Sea.—*Honigberger, p.* 297.

(4810) LAMTENG IN SIKKIM Here birds were scarce, with the exception of alpine pigeons (*Columba leuconata*), red-legged crows (*Corvus graculus, L.* and the horned pheasant (*Meleagris satyra*, L.)—*Hooker Him. Jour. Vol.* II *p.* 37.

(4811) LANCE-WOOD. The timber of a tree (*Guatteria virgata*), indigenous to Jamaica, and which is much valued on account of its exceeding even ash in lightness, strength and elasticity. It is chiefly used for shafts for carriages.—*Faulkner.*

(4812) LANCE-WOOD OF MAULMAIN. There is a tree found all over the Provinces which yields a wood that the residents at Maulmain sometimes call lance-wood. The Karens make bows of it, but prefer *Cassia fistula*. Mr. Mason never met with the tree in flower, but thinks it a species of dalbergia, though it may possibly be a cassia.—*Mason.*

(4813) LANCE-WOOD, OF TENASSERIM. Apocynaceæ. A tree which produces a timber possessing the properties of lance-wood is not uncommon in the Provinces, but it belongs to the dog-bane tribe, and is not at all related to *Guatteria virgata*, the lance-wood of commerce.

(4814) LANIADÆ, a family of Birds including the Shrikes, or Butcher-birds (*Lanius*, Linn). Linnæus places his genus *Lanius* at the end of his first order, *Accipitres*, immediately following the Owls (*Strix*). The *Picæ* form the succeeding order. Cuvier makes the Pies-Grieches (*Lanius*, Linn,) the first great genus of his *Dentirostres*, his second order; the Oiseaux de Proie (*Accipitres*, Linn.) being his first.—*Eng. Cyc.*

(4815) LANSIUM, a genus of Plants belonging to the natural order *Meliaceæ*, established by the late Dr. Jack, and formed of the *Lansium* of Rumph., 2, p. 151, t. 54, which is the *Lansai* of Marsden's 'Sumatra,' pl. v. p. 101, and the Langsah or Langseh of the natives of the Malay Islands. This forms one of the highly-esteemed fruits peculiar to the Malayan Archipelago, or what was termed India Aquosa by old writers, though unnoticed in many works where we might expect to find it fully described. The genus is characterised by—Calyx deeply 5-parted; corolla 5-petalled, petals roundish. The tube formed by the union of the stamens is subglobose, with its mouth nearly entire, having the 10 anthers included within it. Ovary 5-celled, cells with 1-2 ovules; style short, columnar; stigma flat, 5-rayed; berry cortical, 5-celled, 5-seeded, with one or two cells only perfecting their seed;

seeds enveloped in a semitransparent pulpy tunic or aril, exalbuminous; cotyledons unequal, peltate, the short radicle being inserted into their centre. The Lanseh forms a moderate-sized tree with tomentose branches. Leaves alternate, pinnate; leaflets 7 to 9, alternate, short-pedicelled, elliptic-oblong, very smooth; the young leaves are pubescent on the under surface; stipules none; recemes springing from the trunk and naked branches, at first suberect, afterwards drooping by the weight of the fruit. The fruit is of an agreeable taste, according to Marsden, though the skin contains a colouring juice, extremely bitter, and which is apt to taint the fruit if not opened with care. The Ayer-Ayer is another fruit so nearly resembling the Lanseh in most particulars that D. Jack, hesitating to rank it as a species, mentions it as a permanent and well-marked variety under the name var. *B. L. aqueum*. The fruit of the Ayer-Ayer is rounder, and the pulp more watery, and dissolves more completely in the mouth than the Lanseh. Both are highly esteemed by the Malays, and are equally agreeable to the European palate. The juicy envelope of the seeds is the part eaten, and the taste is cooling and pleasant. ('Linnæan Transactions.' xiv. D. 114.)—*Eng. Cyc.*

(4816) LANSIUM, Sp. NAT. ORD. MELIACEÆ.

Var, *a*. Langsat, Malay & Javanese, shape globular.
Var, *b*. Duku „ „ „ oblong.

A genus of plants, consisting of moderately sized fruit bearing trees, and peculiar to the Malay archipelago Europeans regard its fruit as next to the mangostei. It is about the size of a pigeon's egg, having a tough white skin with a bitter taste, and the edible part is the pulpy semitransparent envelope of the seed. —*Crawfurd, p.* 214. At another place he says, Duku, is the Malay and Javanese name of a tree and fruit of the genus Lansium, and natural order Meliaceæ of botanists. To the same genus belong the belangseh, langsat or langsab, for in all this forms the word is written, the rambeh and the ayar-ayar, probably all four but varieties of the same species. The duku is the most esteemed of them, and to the European palate is the best of the native fruits of the Archipelago, after the mangostin. The natives class it after the durian and mangostin. It is of the size of a pigeon's egg, of globular form, and covered with a coriaceous skin of the colour of parchment. The species seems to be indigenous in the western portion of the Archipelago, but to have been introduced into the Philippines where one variety of it, the langseh, is cultivated.—*Crawfurd Dict. page* 125.

(4817) LANTANA, a genus of Plants belonging to the natural order *Verbenaceæ*, named from one of the old names of *Viburnum*, which some of the species somewhat resemble in habit. They are often stated to be confined to America, but a species is found in Arabia, and two in India. They form small or moderate-sized shrubs, often with rugose aromatic leaves, and a somewhat peculiar odour in the clustered flowers, which are either pink, yellows white, or changeable. Piso states that three species, which are confounded together in Brazil under the name *Camari*, are there used for making medicated baths for diseases of the skin. Martius states that the flowers of some species are employed for making demulcent drinks in catarrhal affections. *L. Macrophylla* is employed in infusions as a stimulant, and *L. Pseudo-Thea* as a substitute for tea.—*Eng. Cyc.*

(4818) LANTANA NIVEA :: MUTABILIS. Changable lantana. This straggling shrub appears to be quite naturalized in the neighborhood of Maulmain; though rarely seen in other parts of the Provinces. The flowers are yellow when they first open out, but afterwards change to a rose colour.—*Mason.*

(4819) LANTANA SELLOVIANA. These are large shrubs, producing pink, yellow, orange colored heads of flowers, they blossom at all seasons, and are found in most gardens, the leaves have the scent of black currants, the berries are eaten, may easily be propagated by seed, or suckers.—*Riddell.*

(4820) LAPIS LAZULI, AZURE STONE. A mineral substance of an azure blue colour, with numerous golden spots. When found massive, it is opaque, and its blue colour is not uniform. The finer kind is much prized by the lapidary and the common is used for toys, ornaments, &c. Its chief use, however, is for affording *Ultra marine*, a beautiful pigment, highly valued by painters. Chief localities, China, Persia, Bokhara, Siberia, &c.—*Faulkner.* It is found in Hainan in China, and other parts of Asia. Great quantities of it are procured from the Island of Hainan, in the Chinese Seas. The colour of this stone is a fine azure blue; having little lustre, but susceptible of a fine polish. The Chinese are supposed to use it in painting upon copper and on their porcelain. The beautiful and permanent colour called *Ultramarine*, is prepared from Lapis Lazuli.—*Comp. Desc.*

(4821) LAQUIS. The name given to a variety of the Manilla Hemp Plant, by the Bisayas, by whom the fibres of the original abaca are termed *Lamot*. Rumphius states that the Malay name is *Pissang utan*; that it is called in Amboyna, *Kula abbaal*, in Ternate, *Fana*; and in Mindanao *Coffo*, as also the cloth made from it. He distinguishes the mindanao kind from that of Amboyna.—*Royle Fib. Pl.*

(4822) LARD.
Dukkur-kee-Churbee, HIND.

The fat of the omentum and mesentery of the pig. When properly freed from membranes and

blood by being picked, kneaded in water, melted and strained through linen, it should be white, pultaceous, in thin layers, somewhat tough, without smell, and of a sweetish taste. Lard is employed in the formation of ointments, plasters, liniments, for other medicinal purposes, and also in cookery. *Waterston.—Faulkner.*

(4823) LATHE. Native carpenters make use of a kind of lathe consisting of two rough upright supports mortared into two bars, one of which is fixed while the other may be adjusted by sliding along two slips of wood or bamboo to which it is then fixed by moveable wedges, a boy having in his two hands the ends of a cord passed round the work to be turned causes it to revolve as in the pole lathe: when the work cannot be so fitted the lathe used by brass-smiths is had recourse to: in this a kind of rough wooden mandrel, with a broad face smeared with lac for fixing objects to be wrought, works between a back centre as in the carpenters lathe and a collar shaped, the collar being formed of a plank sawn down the middle and embracing the mandrel which is turned to fit.—*Roxde M.S.S.*

(4824) LATHYRUS APHACA. (Europe), Chuna. Burachuna, *Beng.* ripe seed narcotic *L. Cicera*, (Spain), seeds poisonous. *L. sativus*, Khesaree, Teora, *Beng.* The expressed oil of the seeds is a powerful and dangerous cathartic.—*O'Shaughnessy, page* 317.

(4825) LATHYRUS ODORATUS, Sweet Pea. This genus is formed for the most part of very handsome plants when in flower, but require sticks or trellis work to support them. The seed should be sown after the rains, at the commencement of the cold season, in pots. It is very seldom that they blossom,—*Riddell.*

(4826) LATHYRUS SATIVUS.

Kussoor, Hind.

Kussoor is the Hindoostanee name of a pulse, common in the higher provinces of India, but cultivated in the southern parts of the Peninsula.—*Ainslie p.* 240.

(4827) LAURELS: LAURACEÆ, a natural order of Apetalous Exogens, consisting of trees and shrubs inhabiting the warmer parts of the world, and in most cases aromatic, on which account several are mentioned in works on officinal plants. The best known species in Europe is *Laurus nobilis*, the sweet Bay, a beautiful ever green, whose fragrant leaves are commonly employed to flavour confectionary. Other products of the order are cinnamon and cassia, L. sassafras, whose bark has great reputation in North America as a powerful sudorific; Pichurim beans an indifferent substitute for nutmegs; and finally, not to mention other useful substances, camphor, obtained by the Chinese from the *Camphora Officinarum* by means of dry distillation. In general it may be suspected that the trees of this order are valuable as aromatics and stimulants, although but a comparatively small number has yet been brought into use. They are known by the peculiar structure of their flowers, which has no corolla, stamens in one or several rows, often in part gland-like and sterile, a single-celled superior 1-seeded ovary, and especially by the anthers bursting with recurved valves. [Cinnamomum; Laurus; Nectandra; Benzoin; Sassafras.] There are 46 genera and 450 species of this natural order. Its position is near *Thymelaceæ* and *Cassythaceæ.—Eng. Cyc.*

(4828) LAURUS, a genus of Plants belonging to the natural order *Lauraceæ*, to which indeed it has given its name. It includes as a species one of the most celebrated trees of antiquity, and until recent times some of the most elegant and useful of the vegetable kingdom, as among them were the trees yielding the camphor of Japan, Cinnamon, both of China and of Ceylon, Cassia bark and buds, the Malabathrum leaf of the ancients, with the less known Culilawan and Sintoc barks, as well as the American Persea, Pichurim, and Sassafras. Most of these are however now placed in distinct genera by the latest authors who have paid attention to the subject, as Nees von Esenbeck and Blume.—*Eng. Cyc.* Laurus Camphorifera of Kæmpfer, now the *Camphora officinarum* of Nees, is a native of Japan and of the province of Fokien in China, and also of the island of Formosa, whence, according to Mr. Reeves, the chief portion of the camphor of commerce is brought to Canton. As the wood is said to be valuable, the root, refuse wood, and smaller branches are cut into chips, covered with a little water, and the camphor separated by sublimation. [Camphora.] It is necessary to distinguish this camphor from that produced in Borneo and Sumatra by *Dipterocarpus*, or *Dryobalanops Camphora*. [Dryobalanops.] The kinds of cinnamon are not so clearly settled, as there is both a Ceylon and a Chinese cinnamon. The former however is no doubt produced by *Cinnamomum Zeylanicum*, and the latter by the *C. aromaticum* of Nees. This cinnamon is of superior quality, at least some of it, and is preferred by the Chinese to that of Ceylon, and said to be produced in Cochin China chiefly in the dry sandy districts lying north-west of the town of Faifoe, between 15° and 16° N. lat. Mr. Crawfurd ('Embassy to Siam,' p. 478) informs us that there are 10 varieties of it, and that it is not cured, like that of Ceylon, by freeing it from the epidermis. Dr A. T. Thomson gives this as one of the characters by which cassia may be distinguished from cinnamon. It is possible therefore that some of it may be imported into Europe and sold as cassia, though Mr. Marshall states that the cassia-bark of shops is only a coarse cinnamon obtained from the thick roots or large branches

of the cinnamon tree. Cassia-Buds, or *Flores Lauri Cassiæ*, are the dried receptacles of some species of this family, by some supposed to be the above *C. aromaticum*; but it has been pointed out by Loureiro, and is named *C. Loureirii* by Nees. It is a native of Cochin-China towards Laos, and Japan. [CASSIA-BUDS.] It is sometimes been doubted whether the substances we now call Cinnamon and Cassia are exactly the same things as those to which the ancients applied these names. It is very certain that the substances which formed such highly-esteemed articles of commerce must have possessed some remarkable physical and sensible properties not common in products beyond the tropics. The aromatic principle is that which is most conspicuous in the products of the tropical zone, and is found probably in most of the substances which the ancients obtained from the east—at least Dioscorides has described them all together. It would be difficult even with our present knowledge to find any other substances which would equally well answer the ancient descriptions, without going still farther east. The Greek name of cinnamon is Κιννάμωμον, which Herodotus says his countrymen learnt from the Phœnicians; and the Hebrew name, we know, is Kinnemon. It is remarkable that the Malay name is Kayu-Manis, which Mr. Marshall says is sometimes pronounced as if written Kaina-Manis. By the Hindoos cinnamon is called Dar-Cheence, indicating, that they obtained it from the Chinese; and Professor Wilson has lately proved that there was commerce by sea with China at a very early period, and, what is still more remarkable, that the navigators were Hindoos. The Culilawan Bark, often written Culibaban, or Culitlawan, said to be derived from 'kulit,' bark, and 'lawan,' clove, in some measure resembles Cassia. It is one of those which has been known in Europe since the 17th century, but it has been little used in modern times, though Blume describes it as possessed of remarkable properties in curing diseases. Analyzed by M. Schloss, it was found to yield a resin, a volatile oil, and a bitter extractive substance. A volatile oil obtained from it in Amboyna is used as a stimulant, according to Labillardiere. It was formerly employed in Europe as an aromatic stimulant, and must be useful in cases where such remedies are indicated. The tree yielding it is a native of Amboyna, and is called Cinnamomum Culilawan by Blume.—*Eng. Cyc.* Dr. Wight in Icones gives Laurus, 1833; bilocularis, 1828; cassia, 128-132-140; cinnamomum, 129-136; Culilaban, 137; dulcis, 138; lanceolaria, 1821; multiflora, 131; nitida, 124; obtusifolia, 139; porrecta, 1832; recurvata, 133; and villosa, 1822.

(4829) LAURUS. A solitary post of a species of laurus is often found in Tavoy houses. There was one in Mr. Mason's which the white ants selected in preference to all others; and as long as left undisturbed, they never wandered from home. It may be an advantage to have one post in a house of this timber, but one is quite sufficient.—*Mason.*

(4830) LAURUS CAMPHORA. Lin. CAMPHORA OFFICINARUM. Nees. The Camphor tree is an evergreen, grows to a considerable size, is straight below and branched. All parts emit a camphoraceous odour when bruised. Wood white, fragrant, much used in China for making trunks, boxes, &c. Branches somewhat lax, smooth, with a greenish bark. Leaves alternate, with long petioles, ovate-lanceolate, rather coriaceous, smooth, shining, and bright-green above, paler beneath, triple-nerved, with a sunken gland opening by a pore beneath, at the axils of the principal lateral veins. Leaf-buds scaly. Flowers small, hermaphrodite, smooth externally, in naked, axillary, and terminal corymbose panicles. Perianth 6-cleft, with a deciduous limb. Fertile stamens 9 in 3 rows, the 3 inner supported at the base with 2 stipitate compressed glands. Anthers 4-celled, opening by as many ascending valves, the 3 interior looking outwards, the others opening inwards. Three sterile stamens subalternate with those of the second row, three other stipitate, each with an ovate head. Drupe situated in the truncate cup like base of the perianth.—Native of China, principally near Chinchew in the province of Fokein; also of Formosa and Japan.—Nees von Esenb. 130. St. and Ch. 129.—*Royle.* Mr. Fortune saw near a bridge, a noble specimen of the camphor-tree (Laurus camphora) laid prostrate on the ground having been blown down by a typhoon many years ago. And he tells us that the curious gnarled and angular branches for which this tree is remarkable when it is alive and standing, seemed more striking in its prostrate and withered condition.—*Fortune Residence among the Chin. p.* 39. Dr. Riddell tells us that the Camphor tree of China introduced into Bombay, is a large tree with ascending branches, bark of the stem somewhat rough, but on the inner surface is smooth and mucous. The tree does not blossom until it has attained a considerable size, the fruit is a purple berry the size of a pea, composed of a soft pulpy substance having the flavour of cloves and camphor.—*Riddell.* To this tree it is that the camphor of European commerce is chiefly due.—*O'Shaughnessy, page* 545.—See CAMPHOR. To obtain the camphor, the wood is cut into billets and boiled in water, in iron pots covered with earthenware heads filled with straw; the camphor volatilizes and concretes on the straw. This process is followed in Japan, Sumatra, Borneo, and Malacca. Camphor is a principle found in many plants, but only in two in any great abundance. Camphor, like several substances the produce of countries to the southward or eastward of India, was unknown to the ancients. (Hindoo Med. p. 93.) It

was known to the Arabs, and called by them *Kaphoor*. Camphor is diffused through all parts of the plant, and is separated from the root, trunk, and branches, which when cut into chips, are boiled in water and then sublimed into inverted straw cones contained within earthen capitals. It is thus obtained in the form of *Crude Camphor*, chiefly from the province of Fokien and the opposite island of Formosa, but some of good quality is also procured from Japan. The Dutch exported from thence into Europe 310,520 lbs. in seven years. It is sometimes imported into Britain from Batavia. The ordinary Crude Camphor is in small greyish-coloured, slightly sparkling grains, which by aggregation form greyish crumbling cakes, with all the properties of purified Camphor. In England this is separated from impurities by being mixed with lime and sublimed in thin glass vessels, which being afterwards cracked, the Camphor is obtained in a concavo-convex cake about three inches thick with a hole in its middle. Camphor is solid, colourless, and translucent, with a crystalline texture, has a strong, penetrating, aromatic odour, and a bitter, rather pungent taste, followed by a sensation of coolness; though brittle, it is not, from its toughness, easily pulverized. Sp. Gr. ·98 to ·99; so that it floats on water, and, evaporating, produces a circulatory movement. From its volatility, it volatilizes at ordinary temperatures, and crystalizes on the inside of bottles. —*Royle.*

(4831) LAURUS CASSIA. *Syn.* CINNAMOMUM ALBIFLORUM. Nees. Cassia lignea. Κινναμωμον and Κασσια, Hip. Κασσια, Dioscorid. This is found in Malabar, Sumatra, and Java. The cassia tree (*Laurus cassia*) grows chiefly in Kwangsi and Kweichau, and its dried bark affords the principal part of that spice used in the west. The bark is stripped from the twigs by running a knife along the branch and gradually loosening it; after it is taken off, it lies awhile until decay commences, when the epidermis is easily scraped off, and it is dried into the quilled shape in which it comes to market. The fleshy receptacles of the seeds of this tree, or the pulpy substance which is found in the pods, are also collected, and brought to market under the name of *cassia buds*, being applied to the same purposes as the bark; they require little or no other preparation than simple drying. The leaves and bark of the tree are also distilled and furnish cassia oil, a powerful and pleasant oil employed by perfumers and cooks. The manufacture of it has of late years been interfered with by the officers from an apprehension, as has been alleged, that a want of fuel would ensue if the distillation was not restricted.—*Williams' Middle King. Vol.* II. *p.* 137. Bark, red brown, in fragments of a foot and longer, sometimes in plane pieces a line in thickness, and of variable width or in rolled smooth pieces with a greyish epidermis covered with lichens, chiefly *graphides* and *lecanora*. Hard, inflexible, and with plane fracture. Odour aromatic, agreeable, but weaker than the true cinnamon. Taste sweetish, mucilaginous, rather acrid, bitterish, and tenacious; powder of chamois leather colour. The valuable properties of this bark, depend on its essential oil. Cassia bark is much used for adulterating true cinnamon; it may be distinguished at once, by its very mucilaginous character when chewed. M. Fee places the name of a separate species to this article, but Mr. Marshall is of opinion that cassia bark is merely an inferior kind of cinnamon, obtained from the larger branches and trunk of the true tree. Mr. Marshall's long residence in Ceylon, and his close habits of observation, entitle us to regard his opinion with full confidence.—*O'Shaughnessy, page* 543.

(4832) LAURUS CINNAMOMUM. CINNAMON. Lin.

Karuwa puttay, TAM. Kulmie Darchinie. DUK.	Sanala winga-putta, TEL. *Ainslie's Mat. Med. page* 264.

This tree is rare in the Deccan, and is only to be found in private gardens; where it is most probably introduced from Ceylon, where it blossoms in January and February, the seeds ripen in about four months, the berry is oval about the size of a pea, and when first gathered the taste resembles that of the Juniper berry, and when dry, if boiled, yield a substance which when cold becomes solid like wax, and may be made into candles; propagated by seeds, shoots, or layers; soil a sandy loam mixed with decayed vegetable matter.—*Riddell.*

(4833) LAURUS CULILAWAN. *Syn.* Cinnamomum Culilawan. *Blume.* Telakal, or Sindoc, bark Suleekhe, *Arab.* Selecka, *Mathiolus*, Selechacha, *Avicenna.* Islioos assigned as Greek name.—*Royle, p.* 325. This grows in Amboyna and the Moluccas. The bark of this tree is an aromatic stimulant like Cassia, with some astringency and a flavour of cloves: It contains resin, volatile oil and bitter extractive. Dose 10 grains to ½ a drachm. The oil is used in Amboyna as a stimulating liniment.—*O'Sh. p.* 539.

(4834) LAURUS MALABATHRUM, (Fee.) SYN. Cinnamomum Malabathrum, (Nees and Ebermaier.) Folia malabathri of the ancients.

Leaves, Tej pata, BENG. | Bark Sadrus, Putruj, HIND.

The odour resembles that of cloves; the flavour is aromatic and hot. A native of the Malabar and Coromandel hills, and of the mountain ranges from Sylhet to Missouri.—*O'Shaughnessy, p.* 539.

(4835) LAURUS NITIDA,

Panna-tha, BURM.,

and a second species, are both small trees, about twenty feet high. Their bark is aromatic and affords an inferior kind of cinnamon. They are found in the Pegu and Tounghoo districts.—*McClelland.*

(4836) LAURUS NOBILIS, Sweet bay. *Hub-oolghar* is the Arabic name of the berries, which are still used in medicine in India, with the Greek name Daphne corrupted into *Zakuee* and *Zafuee*.—*Royle*, p. 326.—*OShaughnessy page* 538.

(4837) LAURUS PERSEA. This tree grows to a large size and requires much water. The wood is very brittle. It bears fruit during the rains, the size of a baking pear, but to describe it more accurately would be to say that it is from six to eight inches long, and in the thickest part about three inches in diameter. It is called Subaltern's butter. The outside has a dark green skin, rather thin; and inside a soft whitish pulp, which may easily be divided with a spoon. The seed is about the size of a pigeon's egg, and will grow if planted immediately. The flavor of the pulp is sweeet and creamy, and perhaps the name of Subaltern's butter is derived from this particular taste and appearance. The Natives do not seem fond of it.—*Riddell*

(4838) LAVAJAH TIMBER, short round logs of Timber in the Madras market from 12 to 16 feet in length. 2 to 3½ feet square.

(4839) LAVANDER, the name of hoary, narrow-leaved, fragrant bushes, with generally blue flowers, arranged in close terminal simple or branched spikes. Twelve species have been described, only two of which are of much interest, viz. the common lavender (*Lavandula vera*), and French lavender (L. *spica*). The former yields the fragrant *oil of lavender* used in perfumery, (its solution in spirits of wine forming what is called *lavender-water*,) and the latter *oil of spike*, used by painters on porcelain, and in the preparation of varnishes for artists. [See Essential Oils.] English oil of lavender is most esteemed: it is prepared chiefly at Mitcham in Surrey, where the plant is extensively cultivated for the purpose. It is in highest perfection when about a year old. At first it is nearly colourless, but gradually acquires a pale amber tint. Oil of spike is chiefly imported from the South of Europe —*Tomlinson.*

(4840) LAVANDULA STÆCHAS, (æstakhoodus,) is different in some botanical characters, in other respects nearly the same as the next. It is much prized as an expectorant and antispasmodic by the Arabs.—*OShaughnessy, page* 489 A species of Lavender flower is imported into Bombay from the Persian Gulf, and used medicinally by the natives of India. The Persains term it *Ossa-kuddas.—Faulkner.*

(4841) LAVANDULA VERA AND SPICA, of Decandolle. *Syn.* L. Spica of Linn., and its variety. Europe. Flowers small, bluish, calyx, tubular, cylindrical, streaked, tomentose, corolla infundibuliform, pubescent, tube rather longer that the calyx, limb with five unequal divisions, upper lip large, obcordate, bifid, lower lip trifid. Odour agreeable and penetrating, taste aromatic acrid, rather hot. The volatile oil is limpid, very transparent, yellowish white; four parts contain nearly two of camphor. Often adulterated with the oil of turpentine, and of a species of lavender of superior aromatic power, though more acrid. Lavandula (spica) yields an oil much used by porcelain painters, and called "oil of spike"—*O'Shaughnessy, page* 488. Wight gives Lavandula (Ch.) Burmanni; 1438 (Ch.) Lawii; 1439.

(4842) LAVANDULA VERA.

Sitakepungerie, Duk.

This plant never blossoms in the Deccan, but grows to great perfection on the Neilgherry Hills. The bush there has a strong aromatic scent, but seldom survives more than two years. Is propagated by cuttings and layers, in a good rich soil.—*Riddell.* Lavender, requires pot culture and careful renewing of the stock every season by cuttings, old plants being very uncertain; should be planted in rather poor soil. Seeds sown at the commencement of the rains. —*Jaffrey.*

(4843) LAWANG or KULIT LAWANG. Malay, the clove bark of commerce. According to Crawfurd, this is the bark of the cinnamomum sinto, and takes its name from having a clove flavour. It is a produce of Borneo and an object of export to China.—*Crawfurd, page* 215. See Cinnamomum Culilawan and Laurus Culilawan.

(4844) LAWSONIA, a genus of plants belonging to the natural order *Lythraceæ*, which, consisting of only one or two species, may be found in most oriental regions in gardens or in field cultivation. The genus is characterised by having a 4-partite calyx, 4 unguiculate petals, 8 stamens, a sessile ovary, the capsule scarcely dehiscent, or rather forming a globular membranaceous 4-celled berry, with several angular seeds in each cell. It is disputed among botanists whether this genus consists of one or of two species; in the latter case, one species being armed with thorns, was called *L. spinosa*, and the other being without any, was named *L. inermis*, by Linnæus. De Candolle has followed Lamarck in uniting them together under the name *L. alba*, stating that when young the plant is unarmed, but when older becomes thorny from the hardening of the smaller branches. The natives of North of India distinguish the unarmed species by the name Phoolke, or flowering Mhendee. It is a much smaller plant, but flowers most abundantly. The thorny species is called Mhendee; this, besides being a larger plant, contains a greater proportion of colouring matter, and is extensively cultivated in the vicinity of Sidoura, near the north-west bank of the Jumna. The flowers of both are corymbose, white, and powerfully fragrant; the leaves smooth,

opposite, oval, lanceolate. To the latter species or variety the Arabic name Hinna or Henna is more especially applied, which, in many of their medical works, as in that of Serapion, is described under that of Al Kanna, where it is interesting to observe he quotes the description by Dioscorides of Κύπρος, as applicable to this plant. This Kupros, or Cyprus, is moreover supposed to be the Copher of Scripture. ('Canticl.,' i. 12). Besides the similarity of name, no plant is more likely to have been alluded to in the above passage, as no other is more highly esteemed or more frequently employed than the Hinna, and it would appear to have been applied to the same purposes from very remote antiquity. All oriental travellers describe the use of this plant by Asiatic women in dyeing their nails and the tips of their fingers, as well as the soles of their feet, of an orange hue with the leaves of the Hinna. It is also used by the men for dyeing their beards, the orange colour being afterwards converted to a deep black by the application of indigo. That this plant was similarly used from very early times is highly probable from the allusions to it by poets, as well as from some of the Egyptian mummies appearing as if the nails had been similarly dyed.—*Eng. Cyc.*

(4845) LAWSONIA ALBA. Lawsonia Inermis. The Henna tree is the camphire of the English Bible, and the cypress shrub of the Greeks and Romans. "The cypress plant," says Rosenmuller, "is held in particularly high esteem by the Greeks, the Arabs, and the Turks; and they think that they make an agreeable present when they offer a person a posy of its flowers. In reality, this plant is, as Sonnini observes, one of those which are particularly agreeable to the eye and the olfactory organs. The flowers, of which the coloring is so soft, spread the most delightful fragrance to a great distance, and fill with balsamic odour the gardens and rooms which they adorn." It is extensively cultivated by the Burmese, and hedges formed of it are common in Bengal. The fresh leaves beat up with catechu,

> ——————"Imbue
> The fingers ends with a bright roseate hue,
> So bright that in the mirror's depth they seem
> Like tips of coral branches in the stream."

This use of the leaves is as old as the Egyptian mummies, and is still practiced by Southern Asiatics.—*Mason.*

(4846). LAWSONIA INERMIS. Henna. Egyptian Privet.

Urkan, Arab.	Henna, Pers.
Maritondi, Cyng.	Sakachera, Sans.
Mayndie, Duk.	Maroodanie, Tam.
Mendee, Henna, Guz.Hd.	Gorunta Chettoo, Ivenie, Tel.
Daunlacca, Mal.	

Lawsonia inermis, furnishes an important dye stuff, and the distilled water of the flowers is used as a perfume. The extract of the flowers, leaves, and shoots is used by the Hakims in lepra, and in obstinate cutaneous diseases, half a tea-spoonful being given twice in 24 hours. The Mahomedan women in India use the shoots for dyeing the nails red, and the same practice prevails in Arabia and Barbary. In all these countries the manes and tails of the horses are stained red in the same manner.—*O'Shaughnessy.* *Lawsonia inermis*, Eastern privet: forms a fine hedge and perfumes the air, with a delicious fragrance. The leaf, triturated with rice gruel, or water is used in staining the nails, palms of the hands and soles of the feet, of a red colour. Mr. Faulkner says, a reddish brown substantive dye, is procured from the leaves of the Egyptian Privet (*Lawsonia inermis*). The Mohomedans in India, Persia, Arabia and other countries, use the shoots for dyeing the nails, tips of the fingers and toes, and palms of the hand, red. It is employed in the East for dyeing ordinary stuff; and the extract of the flowers, leaves, and shoots, is used by the hakeems in lepra, and in obstinate cutaneous diseases.—*Faulkner.* Ispund the seeds of the Mayndee are burnt as a charm with benjamin or with mustard seed and Patchouli (Pogostemon Patchouli). It is a hedge plant, resembling the English privet, the wood strong and suited for tool handles, tent pegs, &c., the leaves yield the dye used by the natives.—*Hort. Gard.* 33. Henna (*Lawsonia inermis*), is an important dye-stuff, and the distilled water of the flowers is used as a perfume. The Mahomedan women in India use the shoots for dyeing their nails red, and the same practice prevails in Arabia. In these countries the manes and tails of the horses are stained red in the same manner.—*Simmonds.*

(4847) LEAD. Plumbum. Saturn of the Alchemists.

Sheesh, Duk.	Surb, Pers.
Anuk, Arab.	Olow, Pol.
Hih yen, Chin.	Chumbo, Port.
Lood, Loot, Dut.	Swinetz, Rus.
Plomb. Fr.	Sisaka, Sans.
Bley, Blei. Ger.	Plomo, Sp.
Seesa, Guz. Sheesh.	Eeyum, Tam.
Piombo, It.	Sheshum, Tel.
Plumbum, Lat.	Temettam, Mal.

A soft and flexible metal, of a pale livid gray colour, easily malleable, but slightly tenaceous, and not sonorous. It is of common and extensive use in the arts. Alloyed with tin in different proportions, it forms *solder* and *pewter*; and with antimony it constitutes *type metal*. Combined with oxygen, it forms *massicot*, a protoxide of a pale yellow colour; *Litharge*, also a semi-crystalline protoxide, obtained in separating silver from lead ores, enters largely into the composition of flint glass; *minium* or *red lead*, a duetoxide, extensively used as a paint, and also in the manufacture of flint glass; the *Carbonate of lead* or *white lead*, is a dense white powder, commonly employed as a pigment: the *chromate*

of lead, of a beautiful yellow colour, is also much used as a pigment; and the *acetate or sugar of lead*, is employed for various purposes.—*Waterston.—Faulkner.* Lead (Pb=104) is one of the most anciently known of the metals. It is found chiefly as Sulphuret or Galena, but a little in a metallic state also, as an oxide, and combined with several acids.—*Royle.* At Dessouly in higher Hindoostan about fifty-five coss east of Sirinagur, there is a lead mine of considerable value, worked by the Rajah, and Captain Turner informs us, that at a place situated nearly two days journey from Tessoolumboo, in Thibet, there is one which much resembles some of those in Derbyshire in which the lead is mineralized by Sulphur. In lower India, this metal has been found at Jungumrauzpillay, in the Cumbum District, in combination as far with varying proportions, of Iron, Antimony, Silver, Sulphur, Argil, and Silex. The greater part of the lead however that is met with in the Peninsula comes from Siam, from Araccan and occasionally from the Burmah dominions. It is also a product of Omen in Arabia, but Dr. Ainslie was not aware that it is exported from that country.—*Ains. Met. Med. p.* 56. *Galena or sulphuret of lead.* A rich ore of lead from Martaban containing silver has already been noticed. Another locality from which Galena is exhibited is the Dhone Talook Kurnool, from which Galena in very large blocks has been obtained; one piece measured about 18 inches in diameter and weighed upwards of 3 Cwt. This ore was carefully tested by Dr. Scott some years ago, and was then found to contain from 53 to 70 per cent. of lead but no silver; some of the last consignments are found to be rich in silver: It was also tried at the Mint and yields a large per centage of Lead. It has been used for some years at the Madras School of Arts for glazing Pottery, and answers well for that purpose, though it is found to succeed better when reduced to the form of minium, and then ground with Felspar and an Alkali. The raw galena only answers for the softest and commonest glazes, and the per centage of impurities mixed with this description, varies so considerably, that it has been found safer to reduce it from the state of Sulphuret to that of an oxide before applying it to the wares. Much of the Pottery from the School of Arts has been glazed with this Galena in different states. Galena is also known to occur at the Neilgherries and in two parts of the Cuddapah District. A good sample is exhibited amongst the Chemical substances, from Hyderabad, as Soorma; but this appears to have been purchased in the Bazaar. *Lead containing silver.*—The limestone of the Burmese Provinces probably contains large quantities of lead. In the valley of the Salwen, there is a rich vein of argentiferous galena, which is reported to appear on the surface. A specimen that Dr. Morton sent to England for analysis, was said to be a very valuable Mineral, and destined to make a fortune for some one. Professor Mitchell in the certificate that he furnished Dr. Morton of the analysis, says: "It contains

Lead,	Lime,	} Carbonic Acid.
Sulphur,	Magnesia,	
Silver,	Iron,	
Gold, (traces)	Silica.	

It is a sulphuret of lead or galena. The quantity of lead and silver appears to be considerable, but there was not sufficient of the mineral to estimate either." The ore is seen in the limestone precisely as galena is found in the limestone of the Mississipi, one of the richest known deposits of lead in the world. Mr. O'Reiley states that the carbonate of lead exists near the head waters of the Houngdarau.—*Mason.* The Galena of Jungumrazpilly near Cuddapah, of which a fine specimen was shown at the Madras Exhibition of 1855, has only been procured in small quantities through Capt. Hemery; it has been examined by Dr. Scott.—*M. E. J. R.*

(4848) LEAD BLACK: PLOMBAGO. Is said to be occasionally sold for antimony in the bazars, it is found in Ceylon and Travancore also in the Northern Circar mountains in the Vizagapatam district, though I am not aware of any having found its way into the market, but I understand it has been procured thence by the proprietors of the Bimlipatam sugar works for use in machinery. I have had some from Bangalore of good quality for common purposes, it is found in the hill on which Capt. Orr's house stands.—*Rohde, M.S.S.*

(4849) LEAD, SEMIVITRIFIED OXIDE. LITHARGE. Plumbi Oxydum (Semivitreum) L. D.

Moordarasingy, TEL.	Litharge, FR.
Lithargyrum, ENG.	Protoxide de Plomb.
Oxide of Lead, fused.	Blei-oxyd, GER.

This Oxide of Lead (PbO=112) was known to the ancients, being easily produced when melted. Lead continues to be exposed to a current of heated air. The surface of the metal becomes rapidly covered with a scaly powder of a Sulphur-yellow colour, which is the Protoxide of Lead, and which, being skimmed off, is known in commerce by the name of *Massicot.* When the heat is continued to a bright red, some metallic Lead is separated, the Oxide is fused, though imperfectly, and on cooling becomes an aggregated mass, which readily separates into crystalline scales, of a greyish-red colour These form the *Litharge* of commerce, which varies, in colour, and is called *Gold Litharge* when of a red colour, owing to the presence of a little *Red Lead*, but *Silver Litharge* when lighter coloured. These are frequently obtained in the process of refining Gold and Silver by means of Lead, and in separating the Silver from

Argentiferous Lead. The Litharge of commerce is liable to contain a little Iron, also Copper, Carb. Lead, Silica, and other earths. Litharge, like the other preparations of Lead will affect those exposed to its influence; but it is only employed Pharmaceutically, as for making Diacetate of Lead, and by combining with oil to form the Lead Plaster, which is the basis of several others. —*Royle.* It is used as a drier in painting but seldom the Red lead being preferred by moochies, it is however suitable for rendering oil drying for varnishes.—*Rohde M.S.S.*

(4850) LEAD, RED: MINIUM.

Yerra Sindoorum, TEL. | Gunga Sindooram

Is used both as a pigment and drier by Moochies: it is not manufactured in India.—*Rohde M.S.S.*

(4851) LEAD, WHITE.

Safeda, TEL.

Imported as a paint, when exposed as such it rapidly decomposes the oil with which it is mixed, Oxides of lead should be avoided in all outside work in India.—*Rohde M.S.S.*

(4852) LEAD WORT PLUMBAGINCEÆ, Plumbago. Red colored, Blue, White. The white flowered grows wild.—*Riddell.*

(4853) LEATHER.

The skins of various quadrupeds dressed in a particular manner for the use of manufacturers. For converting skins into leather, different processes are followed, according to the nature and kind of article required, as tanned leather, salted leather, &c.-*Faulkner. Leather* is a chemical art with which the Hindoos have long been acquainted, though it is doubtful whether they ever made leather of very superior quality; but the arts is practised in native states where it is not likely to have been introduced by European influence, as for instance, in Cashmere and in Cutch, whence we have had skins dyed of different colours. But leather of very excellent quality has been sent from the Government farm at Hoonsoor in Mysore, likewise from Calcutta by the Messrs. Teil. The native shields are, however, not to be surpassed.—*Royle Arts &c. of India, page* 484. The manufacture of leather in the Madras Presidency, is by no means so thriving as it might be, considering the great abundance of Tanning materials at command. This is probably owing to the very low rank of the Artisans, (*Chuchlers* or *Chumarwallas,*) for the art of leather production is well understood and successfully practised by the European tanners at Pondicherry, Hoonsoor, Guntoor, Bangalore and Madras, the leather being scarcely inferior to that made in Europe. Goat skins, Sheep skins, Buffalo and Bullock hides are much used and are generally procurable, but are very badly dressed, as many be readily imagined from the excellent description of the usual process given by Mr. Rohde, which accompanied the consignment of leather from Guntoor: indeed, currying the leather being the province of the shoemaker's wife, while manufacturing it for the market belongs to the husband, inferiority of Indian leather may be ascribed to want of skill on the part of the currier, and from the use of quicklime. It is generally acknowledged that there is no better tanning materal than Oak bark—but it has been shown in the class of Leather (including saddlery and harness) that similar substances, if treated with care and skill, may be employed with great success, as for instance, Divi Divi Catechu, Tanghedú Bark, &c., these produce their effects more rapidly, and the leather so manufactured is said to be nearly as durable.—*M. E. J. R.* Leather is a chemical combination of skin with the astringent vegetable principle called *tannin* or *tannic acid.* The manufacture in Great Britain ranks next in importance to that of cotton and of wool, and is probably equal to that of iron. There is a large and constant demand for leather as an article of clothing: it enters into the construction of various engines and machines; supplies harness to our horses, linings to our carriages, and covers to our books. For all the varied purposes to which leather is applied, it is well adapted, and it was probably at the earliest period of man's history that an art so necessary to his comfort and welfare became known. The skins of animals taken in the chase are in their fresh state tough, flexible, and elastic, and seem, at first view, to be well adapted for clothing; but in drying they shrink, become horny, pervious to water, and, on exposure to moisture, putrid and offensive. But if the skin be separated from fleshy and fatty matters, and then be put into a solution of certain vegetables containing tannin, which abound in almost every country, the skin separates the whole of the tannin from the liquid, and becomes hard, insoluble in water, almost impenetrable by it, and incapable of putrefaction. The subsequent operation of currying renders it pliable and more waterproof. Similar but less decided changes are produced upon the skin by impregnating it with alum, and also with oil or grease. The object of these processes being to render soft and flexible that which would otherwise be hard and unyielding, the skin thus transformed was called by our Saxon ancestors *lith. lithe,* or *lither,* —that is, soft, or yielding; whence our term, *leather.* The word *tan,* and the French *tanner,* are from the Low Latin, *tanare.* All tanned leather is classed under the denominations of HIDES, KIPS, and SKINS. From these there are various kinds of leather tanned in Eng-

land: 1st. *Butts* and *backs*: these are selected from the stoutest and heaviest oxhides. The butt is formed by cutting off the skin of the head for glue; also the cheeks, the shoulder, and a strip of the belly on each side. In the *back*, the cheeks and belly are cut off, but the shoulder is retained. 2nd. *Hides* consist of cow-hides, or the lighter ox hides; they are the same as *butts* with the bellies on. Hides are sometimes tanned whole, and are struck for sole leather, in which case they are called *crop hides*. 3d. *Skins*: these are used for all the lighter kinds of leather. The hides of South America are in high repute; they are the produce of the half-wild cattle which pasture on the wide plains between Buenos Ayres and the Andes: Hides are also imported from various parts of Europe, as also from Morocco, the Cape of Good Hope, and other places. They are imported *dry* or *salted*. The following were the imports into the United Kingdom for the years 1850 and 1851:—

	River Plate & Rio Grande.		*East India*	*Horse*
	Dry.	Salted.	Kips.	Hides.
1850,.....	29,820	630,400	1,606,380	231 510
1851,.....	62,640	719,510	2,262,700	140,640

The *butt* or *back* of the ox-hide forms the stoutest and heaviest leather, such as is used for the soles of boots and shoes, for most parts of harness and saddlery, for leather trunks and buckets, hose for fire-engines, pump-valves, soldiers' belts and gloves for cavalry.

Bull-hide is thicker, stronger, and coarser in its grain than cow-hide. The hide of the *bullock* is intermediate between the two. *Calves'-skin* is thinner than cow's, but thicker than most other *skins*. It is tanned for the bookbinder; but the greater part of the supply is tanned and curried for the upper part of shoes and boots.

Sheep-skins are supplied chiefly by the home markets, but many thousands are imported from the Cape of Good Hope, and are considered to be superior to those of English growth: they are distinguished by the greater width of the skin that covers the tail. They are simply tanned, and employed for various purposes for which a thin, cheap leather is required; such as for common book-binding, leathering for common bellows, whip-lashes, bags, aprons, &c. Sheep-skins also form the cheaper kinds of washleather for breeches, gloves, and under-waistcoats; as also coloured and dyed leathers, and mock-morocco, used for women's shoes, for covering writing-tables, stools, chairs and sofas, lining carriages, &c.

Lamb skins are chiefly of home produce; they are also imported from the north of Italy, Sicily, and Spain. They are dressed white or coloured for gloves. The skins of *goats* and *kids* form the best kinds of light leather. The chief supply of the best kid-skins is from Switzerland and Tuscany, whence they are shipped, chiefly at Leghorn.

Goat-skins are principally obtained from the coast of Barbary and the Cape of Good Hope. They form the best dyed morocco of all colours. Kid-skins supply the finest white and coloured leather for gloves and ladies' shoes.

Deer-skins,—are, to some extent, supplied by our parks; but the chief supply is from New York and New Orleans; a few are sent form Canada, and some from India. *Antelope-skins* from the Cape of Good Hope are of good quality. Deer-skins are all *shamoyed*, or dressed in oil, chiefly for riding-breeches. Shamoyed leather, of sheep, goat, and deer-skins, was formerly a lucrative branch of the leather trade of Great Britain. This kind of leather was employed chiefly for breeches, white or dyed, worn by persons who rode much on horseback. The English shamoyed leather was so much esteemed, that it was not only worn by their own cavalry, but by that of Prussia, Austria, and most of the German states. During the Peninsular war, however, it was noticed by the British commander that in wet weather the leathern garments fitted close to the skin, and were long in drying, so that the men were liable to colds, rheumatism, and other complaints arising from this cause. Woollen cloth was therefore substituted, and the example being speedily followed by Austria and Prussia, this branch of the leather trade speedily declined.

Horse-hide,—is tanned and curried for harness work, for collars, &c. It has of late years been substituted for *seal-skin*, but does not produce so good a leather. Enamelled horse-hide, split or shaved thin, is used for ladies' shoes, in imitation of seal.

Dog-skin,—is thin, but tough, and makes good leather. The supply is limited to this country, but has fallen off of late years; horse-leather taking its place for thin dress-shoes. But most of the *dog-skin gloves*, as they are called, are really made of lamb-skin. *Seal-skin* makes a valuable leather, but a large proportion of the supply of seal-skins is used as fur for covering caps.

Hog-skin,—affords a thin, porous leather, which is used for covering the seats of saddles. The common custom of cooking pork with the skin on greatly limits the supply, which is chiefly from Scotland and Yorkshire. The following selection from the "Prices Current," contained in the circular of Messrs. W. T. Goad and Rigg, of Mark Lane, forms a good illustration of the extent and variety of the trade in hides and skins:—

Vegetable Substances used in Tanning.—The tannin or tannic acid of different vegetables does not appear to be the same astringent substance. The differences between tannins from different sources are small, and are chiefly interesting to the chemist. There are, however, certain broad features which are alike in all. Tannin is characterised by an astringent taste, and by its bluish-black or dark-green precipitates from aqueous solutions, by the solution of salts of the peroxide of iron: it also affords a dirty-white or brown precipitate with a solution of gelatine. A solution of protosulphate of iron does not precipitate a solution of tannin, until, by exposure to the air, oxygen is absorbed, and a peroxide of iron is formed. This change, however, is very rapid. If cold aqueous solutions of tannin and animal gelatine (such as glue, size, or isinglass) be mixed in certain proportions, both are thrown down as a precipitate, which is called *tanno-gelatin*: it contains about half its weight of tannin. If heat be applied, or the acid be in excess, the precipitate forms, on stirring, a viscid, elastic mass, resembling caoutchouc. Tannin is most easily procured in its pure state from gall

nuts. These must be coarsely powdered, and placed in a glass percolator, the bottom of which is plugged with cotton. Gallic acid exists ready formed in gall-nuts, sumach, mango-seeds, divi, valonia, tea, &c. and is probably formed in all cases from the decomposition of tannin. It is not so soluble in cold water as tannin, but is very soluble in hot. It does not combine with gelatine or gelatinous tissues as tannin does, and hence is little or no use to the tanner. The tannin of gall-nut and sumach is more liable to pass into Gallic acid than any other description of tannin. This change in the case of gall-nuts, and probably, also, in other cases, is expedited by the contact of the insoluble vegetable matters which remain after the tannin is extracted. Pyroligneous acid retards the decomposition of tannin, while tartaric, malic, and vegetable acids in general, accelerate it. Sumach is peculiarly liable to fermentation, probably in consequence of the malic acid present in the leaves. Hence it is of great importance to the tanner to become acquainted with the circumstances which favour the conversion of tannin into Gallic acid; and to avoid them if possible, for this is a positive source of loss. In the spent or waste tan liquors there is a considerable proportion of Gallic acid. There is an opinion among tanners, that the presence of gallic acid is useful; and when hides have been cleansed with lime-water, they are left for a time in the waste liquor, the gallic acid of which is said to expand the hides, and facilitate the penetration of the solution of tan, when the hide is transferred to a stronger liquor. Now, as almost any other acid would answer this purpose (indeed water soured with sulphuric acid is so used), it certainly does appear to be a circuitous as well as costly method of getting an acid by the decomposition of tannin. *Oak-bark* is the most important tanning material in common use. [See BARK.] It must be stripped in spring, for it then contains more tannin than bark cut in autumn, and this again more than that which is taken in winter. The trees are felled about May: but in some cases, a small quantity is cut down about two months later: this is called *midsummer bark*, but it is now seldom seen in the market. The quantity of tannin is considered by tanners to be in proportion to the freedom with which the sap flows at the time of stripping, and to the facility with which the bark is removed. Bark which has the appearance of having been removed with difficulty, fetches a lower price than that which appears to have come off with ease. The richest bark is obtained in the warmest spring, for then the sap is most abundant. A few days of cold previous to the felling and stripping reduce the proportion of tannin and sap. The bark of coppice trees about 12 years old contains more tan than younger trees, and these more than old ones. According to Stenhouse, the tannin of oak-bark when subject to destructive distillation does not afford pyrogallic acid, as the tannin of gall nuts does: hence the tannin of bark is probably not identical with that of galls. Oak bark contains from 5·6 to 6·0 per cent. of tannin, and in this as in other astringent barks the tannin is contained solely in the inner white layers next the alburnum, the middle coloured portion containing most of the extractive matters, and the epidermis or exterior but little extractive and no tannin. From 4 to 6 lbs. of oak-bark are required for the production of 1 lb. of leather. Leather tanned with oak-bark is considered superior to that made with any other tanning material, but the process is slower. The price of good English oak-bark per load of 45 cwt. delivered in London in June 1852, varied from 12*l.* to 13*l* 10*s*. When the bark has been stripped, the long pieces are set up on end (*stacked*) to dry. In the present year, 1852, after the stacking, a succession of three weeks' rain greatly deteriorated the bark, by washing out a portion of the tannin. *Sumach* is used in the manufacture of the lighter and finer kinds of leather. It consists of the powder of the leaves and young branches of shrubs growing in the south of Europe and known to botanists as *Rhus cotinus*, *Venus sumach*, or the wild olive; *Rhus coriaria*, hide or elm-leaved sumach. The former is used most extensively by the dyer and calico printer; the latter by the tanner. Of late years sumach leaves have been imported entire in consequence of the adulteration which formerly prevailed. Its per-centage of tannin had been found to vary from 16·4 and 16·2 in Malaga and Sicilian specimens, to 10, and 5 in Virginia and Carolina sumach. The tannin appears to be identical with that of galls, and a good deal of gallic acid exists ready formed in sumach. When mixed with water it is more apt to ferment than any other tanning material. The price of Sicilian sumach in June 1852 was from 14*s*. 6*d*. to 16*s*. per cwt. *Divi or divi divi* is the pod of a leguminous shrub, *Cæsalpinia coriaria*, a native of South America, and growing to the height of 20 or 30 feet. It is imported into Great Britain from the West Indias and from various parts of the north coast of South America. The pods are of a dark brown colour, about 3 inches long, but curled up as if by heat in drying. The whole of the tannin exists in the rind below the epidermis; the taste is highly astringent and bitter, but the inner skin which encloses a few flat seeds, is nearly tasteless. Divi contains a considerable quantity of tannin, and also a mucilaginous substance which prevents its being used in dyeing and calico printing. It soon ferments when mixed with water. The leather made by means of divi is very porous, and is of a brown or deep brownish red colour. The colouring matter is produced somewhat suddenly, and appears to be the result of fermentation. If air be excluded the colour is not produced and

the leather is equally good. The price is from 8*l.* to 9*l.* per ton.

Valonia consists of the acorn-cups of *Quercus Ægilops*, or prickly cupped oak, growing in the Morea. As soon as the acorns are gathered they are partially dried, and conveyed by mules to Symrna for shipment. There are here stored in warehouses for some months, in layers of from 3 to 5 feet in thickness. The cups undergo a slight fermentation, and in drying, the long spreading scales which confined the acorn contract, and allow the acorn to fall from the cup. The acorns which contain no tannin are separated from the cups, and those of the latter which are damaged are also picked out. The diameter of the cups including the scales is a little under 2 inches. A small kind of valonia, *camata*, bears a higher price than the common: it is somewhat richer in tannin, and is chiefly used by the silk dyers. Good valonia is thick, full grown, and bright in colour. If exposed to rain after being gathered the cups lose a portion of their tannin and become of a deeper colour. About 2 lbs. of valonia are required for the production of 1 lb. of leather, which is said to be less permeable to water than that made with oak-bark, and so heavy as to make valonia the cheapest of all tanning materials, except catechu or terra. A mixture of valonia and oak-bark may be used with good effect.

Catechu, *cutch*, *terra-japonica* and *terra*, are inspissated aqueous extracts from the bark, wood, and probably the leaves of the *Acacia catechu* and *Uncaria gambir*. In commerce, the two sorts are known as *Catechu*, or *Gambier*, and *Cutch*. Most of the catechu from Bombay is said to be from the former tree, and that from Bengal from the latter. Bombay catechu or cutch is the richer in tannin; it is of a dark brownish red colour, internally as well as externally, and of specific gravity 1·38. Bengal catechu or terra is of a light brown colour internally: its specific gravity is 1·28. Both are astringent and bitter, leaving a sweetish taste on the palate. Catechu is said to be prepared by felling the tree, cutting it up into small pieces, and boiling with water in a narrow mouthed vessel until only one-half of the original bulk of liquid remains. The solution is then transferred to a wide earthen vessel, in which the evaporation is continued; the inspissation is completed by exposure to the sun with occasional stirring. Before the extract is quite dry it is placed in cloths, strewed over with the ashes of cow-dung, cut into small lumps and again exposed to the sun. Mr. Parnell remarks that the appearance of the dark-coloured variety, or cutch, answers better to the description of this mode of preparation than that of the light-coloured variety. This, which is more pulverulent than the former, is said to be prepared by mixing the concentrated decoction of the tree with a pulverulent substance resembling starch. The powder is disposed in a thin layer on a floor or shelf, and the concentrated infusion or decoction allowed to run over the floor, and be imbibed by the powder. When the mass is become stiff by drying, it is cut up into small lumps and dried in the sun. Both kinds of catechu contain about half their weight of tannin, which differs from that of galls in affording olive green precipitates with salts of iron, and yielding no pyrogallic acid on destructive distillation. The tannin of catechu is soluble in cold water. Catechu also affords a peculiar principle, which has been named *catechin* and *catechuic acid*, which is not soluble in cold water, but slightly so in the solution of the tannin of catechu. Catechu is extensively used in India tanning, and of late years has also been much used in this country. It tans the skins with great rapidity, but the leather is light, spongy, permeable to water, and of a dark reddish fawn colour. The light-coloured variety of catechu produces a softer leather than that tanned with cutch. Catechu produces but little of the deposit of *bloom* which is yielded by oak-bark, valonia, and divi. A pound of catechu is said to be sufficient for the production of about a pound of leather. Catechu is used by calico printers, to produce a fast bronze on cotton fabrics.

Myrobalans.—The substance known by this name is the fruit of several East Indian trees, and is used in India as a substitute for galls. When ripe, the fruit is pear shaped, deeply wrinkled, and of a brownish yellow colour: it weighs from 70 to 100 grains. The husk contains the whole of the astringent matter, some mucilage, and a brownish yellow colouring substance, which is used in India for dyeing yellow. The husk is usually separated by bruising the nut, which it encloses. The tannin of myrobalans differs slightly from that of galls. Gallic acid is also present in rather large proportion. The price of myrobalans in June 1852 was quoted at from 5*l.* to 10*l.* per ton.

Mimosa or *Wattle-bark*, is procured from different species of mimosa, which grow in Australia and New Zealand. It is sometimes imported in the form of fluid extract, as well as bark. The leather produced by its means is of good quality, but of bad colour. The bark must be finely ground, or it does not give up the whole of its tannin to warm water.

Cork-tree bark.—The outer dead bark of the cork oak, known as *cork* may be removed without injury to the tree. [see CORK,] but the inner bark which is used in tanning cannot be removed without destroying the tree. In Corsica, Spain, and a few other countries, where the tree is abundant, the bark is removed for tanning. This bark contains twice as much tannin as oak-bark of average quality. The tannin appears to resemble that of catechu: it affords scarcely any bloom and gives a dark colour to the leather.

Larch bark is sometimes used as a substitute for oak bark, for tanning the inferior sheep skins, known as *basils*. It contains a good deal of tannin, mucilage, and some resin.

Willow bark.—The bark of the common willow contains, according to Davy, 2·3 per cent. tannin, and that of the Leicester willow 6·8 per cent. Danish leather, which has a peculiar and agreeable odour, and is used for making gloves, is prepared from kid and lamb skin, by means of willow bark. The same bark is also used in the preparation of Russia leather, but the odour of that leather is produced by the oil of birch tree bark. The following extract from Messrs. Goad and Rigg's Prices Current for 1851, will show the sources and prices of the imported barks. They are all free of duty.

The following table is from a more elaborate one, constructed by Sir H. Davy, to show the value to the tanner of the different substances named. The numbers express the relative quantities of dry hides capable of being tanned by equal weights of the materials:—

Bombay Catechu, ...	261
Bengal ditto.	231
Nut galls, ...	127
White inner bark of Leicester willow, ...	79
Sicilian sumach, ...	78
White inner bark of young oak, ...	77
——————— old oak, ...	72
——————— Spanish chestnut,...	63
Souchong Tea, ...	48
Green Tea, ...	41
Entire bark of Leicester willow, ...	33
——————— oak, ...	29
——————— Spanish chestnut, ...	21
Middle bark of oak, ...	19
——————— Leicester willow, ...	16
——————— Spanish chestnut, ...	14
Entire bark of elm,...	13
——————— Common willow, ...	11

(4854) LEDEBAURIA HYACINTHINA. *Syn.* Erythronium indicum. A native of Bundlecund and Hyderabad. Martius and Ainslie describe the bulbs as a substitute for squill, and the latter writer informs us they are used in cases of strangury and fever in horses. Bulbs sent by Dr. Key, of Bolarum, were slightly acrid and bitter, but although given in double and treble the usual quantity in which squill is employed, they did not in any case produce the marked effects which squill occasions. The bulbs Dr. O'Shaughnessy used had not flowered that season. From trials it would appear that this article holds out but little prospect of its ever being usefully employed in medicine—*O'Shaughnessy, page* 663.

(4855) LEDUM CISTUS. *Ericaceæ.*—Cultivated the same as Lavender.

(4856) LEEA MACROPHYLLA. A curious looking herbaceous plant, with a leaf larger than a cabbage leaf, is sometimes cultivated for the astringent properties of its roots. It is the large-leaved Leea. The Burmans use it to stop the effusion of blood in wounds; but in Hindustan it is said to be a remedy for the Guinea-worm.—*Mason.* Dr. Wight gives also L. staphylea.

(4857) LEECHEE TREE. This is a shady and large tree, some 40 feet high, ornamental, and bears the fruit of that name. It is a delicious fruit, as large as a good sized plum. It produces a very large quantity of fruit, and there is not the least injury to be feared from a free use of it. In that respect, it is like the mango. The fruit is dried in India. Foo-chew Fo, in Fo-kein, in China, is noted for this fruit, and the trade in them in a dried state is extensive.—*Bonynge America, page* 152. See LEECHEE.

(4858) LEECHES. SANGUISUGA, OR HIRUDO MEDICINALIS: nat. cl. ANNULOSA of Macleay.

Aluk, Kheeraheen, ARAB.	Patchet, MAL.
Koodalla, CYNG.	Zeloo, PERS.
Sangsue, FR.	Jaluka, SANS.
Blutigel, GER.	Attei, TAM.
Jouk, GUZ. HIND.	Jalagah, TEL.
βδελλα, GREEK.	Jerika, TEL.

Leeches are common throughout Europe, America and India, inhabiting lakes, pools, &c. There are a great variety of leeches, some of which are considered poisonous,—*Faulkner.* Leeches, the genus Sanguisugo or Hirudo (H. medicinalis) belongs to the family of Hirudinidæ of the class Annelidæ from annulus a ring, and containing the true medicinal leeches, which are procurable in all the stagnant waters of India. In the dry climate of the Dekhan, a caste of Hindoos rear them for hospital use. The full grown leech of Madras and Bengal will draw six drams, but those employed in Bombay scarcely a dram. The numbers of these annelids in most warm parts of the world are immense. When travelling in Sikkim, Dr. Hooker mentions that, between Singtam and Chakoong, he was either wading through deep mud or climbing over rocks.

Leeches swarmed in incredible numbers, in the streams and damp grass and in the bushes: they got into his hair, hung on his eyelids and crawled up his legs and down his back. He repeatedly took upwards of 100 from his legs, when the small ones used to collect on clusters on the instep and the sores they produced were not healed for five months. He thinks snuff or tobacco applied to the feet the best means of preventing their attacks.—*Hook. Him. Jour. p.* 17. He thinks that the extraordinary abundance of these *Anelides* in Sikkim may cause the death of many animals. Some marked murrains have followed very wet seasons, when the leeches appear in incredible numbers; and the disease in the cattle, described to him by the Lepchas as in the stomach, in no way differs from what leeches would produce. It is a well-known fact, that these creatures have lived for days in the fauces, nares, and stomachs of the human subject, causing dreadful sufferings, and death. He has seen the cattle feeding in places where the leeches so abounded that fifty or sixty were frequently together on his ankles; and ponies are almost maddened by their biting the fetlocks.—*Hooker.* The leeches used in the Calcutta Hospitals are caught in tanks and jeels in the direction of Baraset by persons who allow them to fasten on the naked skin. They are to be procured at all seasons; but are occasionally scarce during the months of April and May, when the tanks dry up. The bazar price is two rupees per hundred. In the Upper Provinces a superior kind of leech is used, called the *Shakooabadee jonk*, caught in the tanks about *Shakoabad* in the Agra district. The Punjaubee leeches are the next best, and are procured in abundance about Pateealah in the Sirhind district. The Shakooabadee leech will generally bear three applications, and is the only description of leech that will do so. The animal is of a light olive green colour, and marked with two bright yellow stripes on the sides. The common wild leech of the Upper Provinces is called "Daubree;" but for Hospital purposes it is very inferior to those mentioned. The average price of Shakooabadee leeches varies from three to four rupees per hundred. The Daubrees from eight annas to one rupee per hundred. (*Mr. Daily's notes.*) In Europe leeches are kept in pans with a little soft water, the vessels being covered with canvass to admit the air. In Bengal they are placed in common earthen vessels with moist clay. The common leech used in the Bengal Hospitals averages 50 grains in weight, and draws from two to three fluid drachms of blood.—*O'Shaughnessy, page* 680. In Southern India they are found in almost all pools which are not dry in summer and in which the water is good that is not impregnated with salts.* It is said that cattle are frequently affected by their adhering to their throats when drinking. Mr. Rohde recommended salt to the ryots as a remedy and thinks an addition of salt to the bran mash usually given, an effectual remedy.—*Rohde M. S. S.*

(4859) LEEKS. ALLIUM PORRUM. The native inhabitants of Tenasserim are as much attached to leeks, as the Israelites were to the leeks and onions of Egypt, and they abound in their gardens.—*Mason.* The seed may be sown at the commencement of the rains, or after, in beds, broad-cast. When abut six inches high they require transplanting into large beds, or rows, at leat one foot apart: they go to seed in the course of six months, and grow very well in all parts of the Deccan.—*Riddell.*

(4860) LEGUMINOSÆ, OR FABACEÆ, a very extensive natural order of Plants, consisting of herbaceous plants, shrubs, or vast trees, extremely variable in appearance. The leaves are alternate, most commonly compound, occasionally marked with transparent dots; petiole tumid at the base: stipules 2 at the base of the petiole, and 2 at the base of each leaflet; pedicles usually articulated, with 2 bractlets under the flower; calyx 5-parted, toothed or cleft, inferior, with the odd segment anterior, the segments often unequal and variously combined; petals; 6, or by abortion 4, 3, 2, 1, or none, inserted into the base of the calyx, either papilionaceous or regularly spreading; the odd petal, if any, posterior; stamens definite or indefinite, perigynous, rarely hypogynous, either distinct, or monadelphous, or diadelphous, very rarely triadelphous; anthers versatile; pistil simple, superior, 1-celled, 1- or many-seeded, commonly consisting of a single carpel, but occasionally of 2 or even of 5 carpels; style simple, proceeding from the upper margin; stigma simple; fruit either a legume or a drupe; seeds attached to the upper suture, solitary or several, occasionally with an aril; embryo with or without albumen, either straight, or with the radicle bent upon the cotyledons; cotyledons either remaining under ground in germination or elevated above the ground and becoming green like leaves, always very large in proportion to the radicle, and very often amygdaloid. The most common feature of Leguminous Plants is to have what are called papilionaceous flowers, and when these exist no difficulty is experienced in recognising them, for papilionaceous flowers are found nowhere else. Another character is to have a leguminous fruit: and by one of these two characters all the plants of the order are known. It is remarkable however that one or other of these distinctions disappears in a great many cases. *Cæsalpiniea* have an irregular flower with spreading petals and stamens adhering to the calyx; others have no petals at all, or some number less than five, while *Mimoseæ* have perfectly regular flowers and indefinite hypogynous stamens. *Detarium, Dipteryx*, and others, instead of a legume have a fruit not distinguishable from a drupe. This last circumstance is easily to be understood if we bear

in mind that a legume and a drupe differ more in name than reality, the latter being formed on precisely the same plan as the former, but with this modification, that its pericarp is thickened, more or less fleshy on the outside and stony on the inside, 1-seeded, and indehiscent. Hence some of the regular flowered genera with distinct stamens may be said to be rosaceous in flower and leguminous in fruit. Simple therefore as the diagnosis of this order usually is, Brown is perfectly correct in asserting that, until he indicated the difference of the position of the odd lobe of the calyx in Leguminous Plants and Roseworts, no positive character had been discovered to distinguish the one order from the other. Very few double flowers are known in this order; those of *Spartium junceum* and *Ulex Europæa* are the most remarkable. Two ovaries are common in *Wistaria Sinensis*, and the same phenomenon is to be seen, according to De Candolle, in *Gleditschia*. On account of these and other circumstances, De Candolle assumes the carpel of Leguminous Plants to be solitary by abortion, and that a whorl of 5 is that which is necessary to complete the symmetry of the flowers. In consequence of the highly irritable nature of the leaves of many of the plants of this order, and of the tendency to irritability discoverable in them all, some botanists have placed them at the extremity of their system, in contact with the limits of the animal kingdom. For observations upon the nature of this irritability see Dutrochet, 'Sur la Mortilite,' Paris 1824, in which the author endeavours to show that the motion is the effect of galvanic agency; and the same writer's 'Nouvelles Recherches sur l'Exosmose,' in which he alters the explanation of the manner in which galvanism produces the motion, adhering however to his opinion of that subtle principle being the real agent. It is more probable however that these movements are connected with the inherent irritability of the protein common to all plants. In many respects this order is one of the most important which the botanist can study; more especially as it serves to show how little real importance ought to be attached to dehiscence of fruit in determining the limits of natural orders. What may be called the normal fruit of Leguminous Plants is a legume, that is to say, a dry simple carpel, with a suture running along both its margins, so that at maturity it separates through the line of each suture into two valves; but every conceivable degree of deviation from this type occurs. *Arcahis* and many more are indehiscent; in *Carmichælia* the valves separate from the suture, which remains entire, like the replum of *Cruciferæ*; in all Lomentaceous genera such as *Ornithopus*, the valves are indehiscent in the line of the suture, but separate transversely; in *Entada* a combination of the peculiarities of

Carmichælia and *Lomentaceæ* occurs; in *Hæmatoxylon* the valves adhere by the suture and split along the axis; and finally, *Detarium*, *Dipteryx*, and others, are true drupes, in no respect different from those of *Amygdaleæ*. The geographical distribution of this order has been considered with great care by De Candolle, from whom the substance of what follows is borrowed. One of the first things that strikes the observer is, that if a number of genera of Leguminous Plants have as extensive a range as those of other orders there is a considerable number of which the geographical limits are clearly defined. Thus the genera of Australia are in most cases unknown beyond that vast island; the same may be said of north and south America, and the Cape of Good Hope, and there are 14 or 15 genera unknown beyond the limits of Europe and the neighbouring borders of Asia and Africa. About 62 genera out of 280 are what are called sporadic, or dispersed over different and widely-separated regions, such as *Tephrosia*, *Acacia*, *Glycine*, and *Sophora*. The species are found more or less in every part of the known world, with the exception of the islands of Tristan d'Acuhna and St. Helena, neither of which do they inhabit; but they are distributed in extremely unequal proportions. In general they diminish sensibly in approaching the pole. This will be apparent from the following table;—

Europe, with the exception of the Mediterranean.	184
Siberia.	129
United States.	183
China, Japan, and Cochin China.	77
Levant.	250
Basin of the Mediterranean.	468
Canaries.	21
Arabia and Egypt.	87
Mexico.	152
West Indies.	221
East Indies.	452
Equinoctial America.	605
Equinoctial Africa.	130
Australia.	229
Isles of Southern Africa.	42
South America beyond the tropics,	29
Cape of Good Hope.	353
South Sea Islands.	13

This distribution, if condensed, will give the following results:—

Equinoctial Zone.	1602
Beyond the Tropics to the North.	1312
Beyond the Tropics to the South.	524

Since the time this calculation was made the order has been prodigiously enlarged and a very considerable number of species has been added to those from the tropical parts of America, Australia, and the Cape of Good Hope. Nevertheless the calculation, with these exceptions, is instructive as a general sketch of the statistics of this branch of Geographical Botany. [illegible] Legu-

minous order is not only among the most extensive that are known, but also one of the most important to man, whether we consider the beauty of the numerous species, which are among the gayest coloured and most graceful plants of every region, or their applicability to a thousand useful purposes. The properties of the order are very various; some are nutritious, others tonic and astringent, others purgative, and some poisonous. The plants supply timber, fibres, gum, dyes, and various other economical articles. There is however to be borne in mind, in regarding the qualities of this order in a general point of view, that upon the whole it must be considered poisonous, and that those species which are used for food by man and animals are exceptions to the general rule. The species amount to some thousands, and are conveniently divided into three sub-orders, *Papilionaceæ*, *Cæsalpiniceæ*, and *Mimoseæ*. *Papilionaceæ*, Pulse section, have what or called papilonaceous flowers, that is of the five petals one is large, broad, spread open, and called the standard; two others are parallel, convex, or slightly spreading, and called wings; and the two remaining ones are also parallel, but united by their anterior edge so as to form a body not unlike the keel of a boat, after which it is named. In all these plants the stamens are definite in number, and inserted with tolerable distinctness into the calayx; but while many are diadelphous, others are monadelphous or decandrous; the fruit is either a legume, a lomentum, or a drupe, or some form intermediate between the first and last. It is here that the great mass of the order occurs, especially in the colder parts of the world. Peas, beans, clover, saintfoin, lucern, liquorice, indigo, medicks, and trefoils, lupines, and numerous other common European genera, belong to *Papilionaceæ*. Many species are tonics and astringents, and others yield a kind of gum, and among those that yield dyes is the *Baptisea tinctoria*, the Wild Indigo of America. In a very large number of species narcotic properties have been discovered. The descriptions of the useful genera will be found under their respective heads, such as Astragalus, Butea, Colutea, Cytisus, Indigofera, Ervum, Glycyrrhiza, Geoffroya, Mavia, Crotalaria, Melilotus, Triptolomea, &c., &c. The sub-order *Cæsalpiniceæ* have the petals spread out, and nearly equal-sized, with distinct unequal stamens; they may be considered the regular form of the order, while *Papilionaceæ* are the irregular form. Their fruit is usually a legume, but not always. The *Cassia*, which furnishes the senna-leaves of the shops, is the most interesting among them; to this sub-order also belong the Tamariud and Algaroba fruits, the trees yielding Logwood, Brazil-wood, Sappan-wood, &c., and *Hymenæa*, from which gum anime is procured. Purgative properties are the great characteristic of this sub-order. Senna is their most remarkable product. Some of them yield dyes. The Locust-Trees of North America belong to this order, and are celebrated for their gigantic stature. The principal species are described under Cassia, Ceratonia, Copaifera, Hæmatoxylon, Hymenæa, Robinia, Tamarindus, &c.

The sub-order *Mimoseæ* have small regular flowers collected into heads, numerous often indefinite stamens, usually hypogynous, and a legume. They are unknown in cold countries in a wild state, but in the hotter parts of the world they form a strikingly beautiful portion of the vegetation. From the much greater length of their stamens, their petals, and the clustered compact arrangement of their flowers, the latter often resemble tassels of silk, of the most vivid colours, intermingled among the leaves. Their bark is usually astringent, with a frequent intermixture of gum. The gums Arabic, Senegal, Sassa, and others, are produced by different species; catechu is the extract of the astringent bark of *Acacia Catechu*, and the timber known in England as rose-wood is said to be the timber of some *Mimosa* inhabiting the interior of Brazil. One of the most striking phenomena among the plants of this order is the excessive irritability observable in the leaves of certain species of *Mimosæ*, such as *M. pudica*, *M. sensitiva*, which are hence called Sensitive Plants. It is however a special peculiarity, and not one of general occurrence; unless the folding up at night of the leaves of the whole sub-order be regarded as an instance of the same irritable quality in a low degree. The species of this order are described under Acacia, Entada, Mimosa, &c.

(4861) LEIOSAURUS. [Iguanidæ]

(4862) LEIOTRICHANÆ (Swainson), a subfamily of the *Ampelidæ*, a family of Birds. It is thus defined by Mr. Swainson:—Legs large robust, syndactyle: hind toe longer than the outer; wings short and rounded; bill strong; the gonys ascending. The only other genus besides *Leiothrix* placed in this sub-family by Mr. Swainson as *Pteruthius* (Sw.) to which that author gives the following generic characters;—Bill short compressed, thick; the tip shrike-like-hooked; culmen arched; gonys ascending; nostrils basal; the aperture round; gape wide; rictus slightly bristled; wings very short, rounded; tail short, broad, rounded; the tips obtuse; tarsi smooth, pale. *P. erythropterus*, Gould's 'Century of Himalaya Birds,' pl. 11. *Lanius erythropterus*, India, is an example.

(4863) LEIOTH[illegible], a genus of Birds established by Mr. Swainson, with the following generic characters:—Bill much compressed; culmen gradually curved; nostrils large, membranaceous; tail moderate, deeply forked.

(4864) LEIOTHRIX, a genus of Birds established by Mr. Swainson, with the following generic characters :—Bill much compressed ; nostrils large, membranaceous ; tail moderate, deeply forked.—*Eng. Cyc. Vol.* III. *p.* 380.

(4865) LEIOTRICHANÆ [Swainson] a subfamily of the *Ampelidæ*, a family of Birds. It is thus defined by Mr. Swainson, Legs large, robust, syndactyle ; hind toe longer than the outer : wings short and rounded ; bill strong ; the gonys ascending.—*Eng. Cyc. Vol.* III. *p.* 380. The only other genus besides *Leiothrix* placed in this subfamily by Mr. Swainson is Pteruthius [Sw], to which that author gives the following generic characters :—Bill short, compressed, thick ; the tip shrike like, hooked ; culmen arched ; gonys ascending ; nostrils basal, the aperture round ; gape wide ; rictus slightly bristled ; wings very short, rounded ; tail short, broad, rounded ; the tips obtuse, tarse, smooth, pale. *L. erythropterus*, Gould's "Century of Himalaya Birds," pl. II. [*Lanius* erythropterus], India, is an example.—*Eng. Cyc. Vol.* III. *p.* 380.

(4866) LEMMUS, [Muridæ].

(4867) LEMNA MINOR, the common Duckweed grows in the Sikkim Himalaya.—*Hooker Vol.* I. *page* 306.

(4868) LEMON.

Lemoon, Arab.	Limoni, It.
Limoenen, Dut.	Leembo, Pers.
Limons, Fr.	Limoes, Port.
Limonen, Ger.	Limonu, Rus.
Limboo, Neemboo, Guz. Hind.	Limones, Sp.

The fruit of a tree of the citron or orange family, a native of Eastern Asia, Assyria, Persia, and now cultivated in different parts of Europe.

(4869) LEMON. [Citrus.]

(4870) LEMON GRASS, Andropogon schænanthus. Camel's Hay, Sweet Rush.

Askhur, Arab.	Malatrinakam, Sans.
Gundha-bena, Beng.	Camachie-Pilloo, Wassina-Pilloo, Cavatum-Pilloo, Tam.
Gund-beyl, Olacha, Guz. & Hind.	Kamachie kussoo, Tel.
Seeree, Jav.	
Gowr-geea, Pers.	

A sweet-smelling, bitterish, aromatic grass, having long, striated, scabrous leaves, which are frequently used as a substitute for tea, and the white succulent centre of the leaf bearing culms, is often put into curries to give them an agreeable flavour. An infusion of the leaves is also used medicinally by the native Hakeems, who consider them to be tonic and stimulant. Sweet rush is much cultivated in gardens in Bombay, on the Coromandel Coast, and extensively in the north of Bengal.—*Faulkner*. This flourishes in any good soil. It is propagated by slips from the root, and only requires watering. It is used as an infusion.—*Riddell*. Lemon-grass is cultivated by natives all over the Tenasserim Provinces, and a decoction made from the leaves is deemed by them of much efficacy in cholic, and similar complaints.—*Mason*. In Madura, are the three sorts of grass named "Poathapil," "Seegompil" and "Comatchipil." To make oil, each sort of the grass should be cut in pieces of one span long (the little roots excepted) and the same put into earthern pans separately. Their subsequent exposure to the warmth of fire will extract the oil. Madura, 14th September 1850. (Signed) R. D. Parker, Collector. (True copy) E. Maltby, Collector. The following is a Memorandum by Ross and Co. Of the efficacy of Lemon Grass Essential Oil. "Of its use and properties, particularly in Rheumatic cases, there can exist no doubt, as those (and there are many) who, happened to languish under its acute pains and who had felt an instantaneous relief by the application of it outwardly—would, we feel assured, join us in recommending it to the community in general. Its properties and intrinsic worth even as a perfume of other oils are well known in England and therefore need hardly he recapitulated in this place.—*M. C. C.*

(4871) LEMON JUICE, Lime Juice.

Jus de limon, Fr.	Limboo-ka-rus, Hind.
Zitronen saft, Ger.	Jugo de limon, Sp.
Agro o sugo de limone ; It.	

The expressed juice of limes or lemons. It is an approved specific in the prevention and cure of scurvy ; a powerful and agreeable antiseptic ; as well as an ingredient in many pleasant refrigerant drinks. Lime juice is imported in large quantities into Bombay from Cambay.—*Faulkner*.

(4872) LEMON GRASS OIL, Andropogon. (Schænanthus.)

Camachie Pillo Tylum, Tam.

This well known Oil, Camachie Pilloo Tylum, *Tam.* is obtained by distillation from the above grass, which grows plentifully in many parts of the country. It is much used as a rubefacient for Rheumatic affections, as well as in Perfumery, for which purposes it is said to be largely exported from Travancore. When newly made, this Oil is of a light straw color, but age changes it to a deep red.—*M. E. of* 1855. Another Oil of Lemon grass or Citronelle, the produce of "*Andropogan Citratum*," was exhibited from Travancore, and also from Ceylon, by Mrs. Goodsir.

(4873) LEMON PEEL.

Lames de ecorce de citron, Fr.	Limboo-ka-chall, or chilta, Hind.
Zitronenshalen, Ger.	Scorze de limone, It.
	Cortezas de citra, Sp.

The rind of the lemon is a bitter aromatic, and is frequently employed in stomachic tinctures, and for making preserves and liqueurs ; it also yields an essential oil, which is much used in perfumery.—*Faulkner*.

(4874) LEMUR. [Lemuridæ.]

(4875) LEMURIDÆ, a family of Animals belonging to the *Quadrumana*. Linnæus, in his 'Characteres Mammalium,' defines *Lemur*, the

third genus of his *Primates*, thus—"Dentes primores inferiores 6." In the body of the work ('Syst. Nat.') he characterises the genus as follows:—Upper incisors (primores) 4; the intermediate ones remote; lower incisors 6, longer, prominent (porrecti), compressed, parallel, and approximate. Canines (laniarii) solitary, approximate. Molars numerous (plures), sublobate, the anterior ones longer and more acute. The genus consists of *Lemur tardigradus*, *L. Mongoz*, *L. Macaco*, *L. Catta*, and *L. volans*. To these species Gmelin added *L. Indri*, *L. Potto*, *L. murinus*, *L. bicolor*, and *L. laniger*. *Stenops* is Illiger's name for a genus of *Prosimii*, his third family of his second order, *Policata* of *Mammalia* including the genera *Loris* and *Nycticebus* of Geoffroy. Mr. Bennett, in his 'Garden and Menagerie of the Zoological Society,' observes that in an early memoir on the family to which the Slow-Paced Lemur belongs, M. Geoffroy St. Hilaire divided it for the first time into those minor groups of which it was most obviously composed. But Mr. Bennett remarks that M. Geoffroy has since carried the principle of subdivision to a still greater extent by separating the Slow-Paced Lemur from the slender *Loris*, with which he had previously associated it, in order to form from it and some other doubtful species the genus *Nycticebus*. Mr. Bennett cannot perceive any sufficient grounds for thus disuniting two animals so intimately allied to each other, and differing in no more essential characters than the somewhat greater length of the nose and of the limbs in the one than in the other. For this reason Mr. Bennett prefers M. Geoffroy's older arrangement, and proceeds, in accordance therewith, to describe the Slow-Paced Lemur as a species of *Loris*, which he considers to be a well-marked and circumscribed natural genus, differing from the Lemurs of the same author in many highly important characters. The following are the generic characters of *Loris* and *Nycticebus*, Geoffroy:—

Loris.—Four upper incisors; six lower incisors inclining forwards; head round, eyes very large, limbs very slender, no tail; four mammæ coming from two mammary glands only. The tibia longer than the femur; ears short and hairy.

$$\text{Incisors, } \frac{4}{6}; \text{ canines, } \frac{1-1}{1-1}, \text{ molars, } \frac{6-6}{5-5} = 36.$$

Species.—1. Loris Grele, *Loris gracilis*, Geoff.; Le Loris, Buffon; Le Tardigradus, Seba. 2. Loris de Ceylon; *Loris Ceylonicus*, Fisch. The locality assigned to both these species is Ceylon; but, according to M. Lesson, neither Geoffroy, Desmarest, nor F. Cuvier admit the second species, regarding it as a simple variety differing hardly at all from *Loris gracilis*.

Nycticebus.—Head round; muzzle short; eyes very large; ears short and hairy; a tail more or less long; extremities strong and robust.

$$\text{Incisors, } \frac{4}{2}; \text{ canines, } \frac{1-1}{1-1}, \text{ molars, } \frac{6-6}{5-5} = 34 \text{ or } 36.$$

The species are—*N. Bengalensis*; *N. Javanicus*; and *N. Ceylonicus*. All from the East Indies. We here adopt Mr. Bennett's view of the subject, and take the Slender Loris and the Slow-Paced Loris, or Slow-Paced Lemur, both of which are confounded by Linnæus under the name of *Lemur tardigradus*, as examples of the genus *Loris*.

Loris gracilis,—the Slender Loris, has the visage produced and dog-like; forehead high above the nose; ears large, thin, and rounded; body slender and weak; limbs very long and slender; thumb on each foot more distinct, and separate from the toes; on that and the three outmost toes are flat nails; on the interior toe of every foot a crooked claw; no tail; the hair on the body universally short and delicately soft; the colour on the upper part tawny, beneath whitish, space round the eyes dusky; on the head is a dark-shaped spot with the end pointing to the interval between the eyes. Length from the tip of the nose to the anus only eight inches.

Loris tardigradus, the Slow-Paced Lemur.—The most accurate description known to us is that given by Mr. Bennett:—"The Slow-Paced Lemur," he says, "is an animal of small size, scarcely equal to that of a cat. The largest individual yet noticed appears to be that seen by Pennant, who states its length at no less than 16 inches from the nose to the extremity of its back. Its proportions are short and thick-set; and the apparent clumsiness of its form is much increased by the manner in which it usually contracts itself into a kind of ball. Its head is broad, flat, and rounded, with a slightly projecting and pointed muzzle, in which the nostrils are perforated laterally. Its eyes are large and perfectly orbicular, and furnished with transverse pupils capable of being entirely closed during the day, and of being very largely dilated at night; their inner canthus is situated so low towards the nose that the motion of the eyelids appears to take place in a diagonal instead of a horizontal direction. The ears are short, round, widely open, but buried in the fur; and the tail is merely a rudiment of a few lines in length. The hinder limbs are considerably longer than the fore. The whole of the body, with the exception of the muzzle and hands, is thickly invested with long close woolly hair of a deep ashy gray with something of a brownish tinge. A deep brown or chestnut band passes along the middle line of the back, and is accompanied on either side by a faint grayish stripe, expanding on the back of the head into a still lighter patch. The dark middle stripe divides on the head into

two branches, each of which is again subdivided, the posterior division passing transversely across the forehead and inclosing the ear, the anterior crossing the eye obliquely and extending to the angle of the mouth. Between the two, above the outer angle of the eye, is a large white spot. Each of the eyes is surrounded by a ring of dusky black, between which a narrow white line passes from the back part of the head to the tip of the nose, which, with the exception of the naked muzzle, is also white. The latter, together with naked parts of the hands, is of a livid flesh-colour with a tinge of black. On the under surface the fur is of a lighter gray than above."—*Eng. Cyc.*

(4876) LEONOTIS LEONURUS. *Labiatæ.* SCARLET DANDELION. A beautiful small scarlet flower, native of the Cape, and now common in all Indian gardens; blossoms throughout the year, and is very difficult to get rid of when once sown: any soil seems to suit it.—*Riddell.*

(4877) LEONURUS TATARICUS. *Stachydeæ.* Tartarian Motherwort. This is a shruby plant grown from seed and cultivated in some gardens.—*Riddell.*

(4878) LEPIDUM SATIVUM. GARDEN CRESS.

Haleem DUK. BENGAL.

Aliverie of the bazars. The aliverie seeds of the bazar, which were referred by Rottler and Ainslie to the Arabis Chinensis, have been ascertained by Dr. Wight to belong to the garden cress, which Roxburgh informs us is cultivated universally in Asia during the cool season. The seed is of reddish colour, agreeable warm taste, and is used by the native physicians as a gentle stimulant. Bruised and mixed with lime juice, it is deemed useful for checking local inflammation.—*Ainslie*, vol. ii. p. 12. Taken whole in half drachm doses, we find also that it answers as a gentle and warm aperient—*O'Shaughnessy, page* 188.

(4879) LEPIDOPTERA. In the winged insect-world, there are numerous species common to the two regions: among the most prominent of which, appertaining to the *Lepidoptera*, are the cosmopolite *Cynthia cardui* (or 'Painted Lady' butterfly) at all elevations, the *Papilio machaon* (or English 'Swallow-tail' butterfly) in the Himalaya, the *Colias edusa* (or 'Clouded-yellow' butterfly) and the *Argynnis lathonia* (or 'Queen of Spain') also common in the Himalaya, *Sphinx convolvulus* at all elevations, &c.; but others are represented by nearly similar species, which are considered different upon comparison, as the 'Purple Emperor' (*Apatura*), and 'Common Sulphur' (*Gonepteryx*) butterflies, and others which are more obviously different, as *Vanessa vulcania* of the Himalaya compared with *V. atalanta* of Europe. Two species of 'Death's-head' Moths (*Acherontia*) are common to all habitable elevations; and one of these is exceedingly similar to that of England (*Ach: atropos*); but is nevertheless considered by the eminent entomologist Westwood to be distinct.

(4880) LEPORIDÆ, a family of *Rodentia*, the type of which may be considered as existing in the Common Hare. Mr. Swainson defines the genus *Lepus* thus:—Cutting teeth $\frac{4}{2}$, the upper in pairs two in front, large and grooved, and two smaller behind; lower teeth square; grinders $\frac{6-6}{5-6}$, composed of two soldered vertical plates; a sixth, very small, in the upper jaw; soles of the feet hairy; anterior feet with five toes; posterior with four; tail very short, turned upwards.—*Eng. Cyc.*

(4881) LEPTADENIA SPARTEA, The fibre of another species of the genus, *L. Jacquemontiana*, was described to Dr. Royle by Dr. Stocks, as employed in Sindh with *Periploca aphyllum* for making into ropes and bands used for wells, as water does not rot them.—*Royle Fib. Pl. page* 306.

(4882) LEPTOPHIS (BELL). Some of this genus inhabit Mexico, and Brazil; and three are Asiatic, two from the East Indies and one from the island of Java. Rostrum obtuse; upper jaw projecting, but very slightly beyond the lower. Mr. Bell records three species, two from the East Indies, and one from America (Carolina). To these Dr. Gray subsequently added two species, *L. punctulatus* and *L. spilotus* (*Coluber spilotus*, Lacepede) collected by the expedition under Captain Phillip Parker King, R. N. ('Survey of Australia.')

(4883) LEPTOPHIS PURPURASCENS, (COLUBER PURPURASCENS, Shaw). Violet, changing to green, gilded; a lateral and dorsal line of a paler hue; head obtuse. It is found in the East Indies. ('Zool. Journal,' vol. ii.)—*Eng. Cyc.*

(4884) LEPTOSIPHON. POLEMONIACEÆ. These are pretty annuals allied to the Gilia, and propagated in the same manner, the colours are white, blue and purple.—*Riddell.*

(4885) LEPURANDA SACCADORA: ANTIARIS SACCADORA. Netavil Marum or Chundul. A stately forest tree, called Chandul, *Lepurandra saccadora*, is indigenous on the West side of India, as in the ravines at Kandalla and in the jungles near Coorg, where people manufacture sacks from the bark by a very simple process. A branch is cut, corresponding to the length and diameter of the sack wanted. It is soaked a little, and then beaten with clubs until the inner bark separates from the wood. This done, the sack formed of the bark is turned inside out and, pulled down, until the wood is sawed off, with the exception of a small piece left to form the bottom of the sack, and which is carefully left untouched. These sacks are in general use

among the villagers for carrying rice, and are sold for about six annas each.—*Royle. Fib. Pl. page* 348. This is very common and the most gigantic of all the trees in the Wynaad Jungles: Coorumboor bags or sacks are made from the bark: wood not much used.—*Melvor.*

(4886) LEPUS ÆGYPTICUS, Egyptian Hare. Egypt.

(4887) LEPUS CUNICULUS Linn, the Rabbet, Rabbit, or Coney; Coniglio of the Italians; Conejo of the Spanish; Coelho of the Portuguese; Kaninchen of the Germans; Konyn or Konin of the Dutch and Belgians; Kanin of the Swedes; Kanine of the Danes; and Cwningen of the Welsh, is known to every one. The fertility of the animal may be imagnied when it is remembered that it will begin to breed at the age of six months, and produce several broods in a year, generally from five to seven or eight at a time. Pennant says :—"Rabbits will breed seven times a year, and bring eight young ones each time. On a supposition that this happens regularly during four years, their numbers will amount to 1,274,840." The young are blind at their birth, and nearly naked. The fur of the Rabbit is in considerable demand, particularly for the hat trade; and at one time the silver-haired varieties, or silver-sprigs, fetched three shillings a piece, for ornamental linings to cloaks, &c.; in Pennant's time however the price had fallen to sixpence. The following additional species of Asiatic *Lepus* are found in the 'British Museum Catalogue.'

(4888) LEPUS DIOSTOLUS, the Woolly Hare of Thibet. Nepaul. LEPUS DIOSTOLUS. At another place, this author names another Lepus. There was, he says, much short grass about the lake on which large antelopes, "Chiru" (Antilope Hodgsoni), and deer, "Goa" (*Procapra picticaudata*, Hodgson), were feeding. There were also many slate coloured hares with white rumps (*Lepus diostolus*), with marmots and tail-less rats.—*Hooker Him. Jour. Vol.* II. *page* 157. He found the horns of the Chiru on the south side of the Donkia pass, but he never saw a live one except in Tibet. The *Procapra* is as described by Mr. Hodgson.—"*Bengal As. Soc. Jour.* 1846, *page* 338," *Hooker Him. Jour. Vol.* II. *page* 157.

(4889) LEPUS HISPIDUS, the hispid hare occurs at Siligoree in the Terai. It is the best game of this part of the country.—*Hooker Him. Jour. Vol.* I. *p.* 399.

(4890) LEPUS KURGOSA, the Lada, or Khargosh.

(4891) LEPUS MACROTUS, the Indian Hare. Nepaul.

(4892) LEPUS TIMIDUS, the Common Hare.

(4893) LETROMIA SETOSA. HAIRY LETSOMIA. A large red flowered creeper of the convolvulus tribe, and genus letsomia is seen in Tenasserim during the rainy season on almost every hedge.—*Mason.*

(4894) LETTSOMIA, Dr. Wight gives of this genus aggregata, 1359; cymosa, 889; setosa, 1360.

(4895) LETTUCE.

Kahoo, GUZ. HIND.

A well-known succulent vegetable (*Lactuca Sativa*), cultivated in Europe, in most of the European colonies, India, and other places. After its flower stem shoots, it abounds with a milky juice possessing soporific powers, which, in the strong scented wild lettuce (*Lactuca virosa*), is so abundant, that it has been used as a substitute for laudanum and opium; it is termed lactucarium.—*Faulkner.* There are various sorts of Lettuce: the most esteemed are the cabbage, red and brown cos-lettuce. For early salading the seed may be sown at the commencement of the rains, although neither are in perfection until the cold season. They are mostly raised in small beds, and then transplanted into others at about one foot apart, or on ridges around other vegetables; they do not require any particular care. The ground should be light and rich, and when the plants are of a sufficient size they should be tied up; and this may be done with shreds of plantain-leaf or twine.—*Riddell.*

(4896) LEUCADENDRON. PROTEACEÆ. These are a handsome genus of shrubs, growing to a large size, with heads of yellow flowers, and silky leaves, and may be cultivated in any good garden soil.—*Riddell.*

(4897) LEUCAS, Dr. Wight gives of this genus, in Icones, Leucas biflora, 866; cephalotes, 337; *helianthemifolia*, 1435; *Indica*, 1451; (A.) lanceæfolia, 1452; nepetifolia, 867; (A.) rosmarinifolia, 1455; (A.) suffruticosa, 1454; (A.) ternifolia, 1453; (H.) urticæfolia, 1451; vestita, 338.

(4898) LEUCAS ASPERA, *Syn*: PHLOMIS ESCULENTUM.

Thoombaykeera, TAM.

A small annual weed with white flowers; appears during the rains; the leaves are used as greens mixed with others.—*Jaffrey.*

(4899) LEUCOSPERMUM. PROTEACEÆ. An interesting genus of plants, with entire downy, or hairy leaves, and terminal heads of yellow flowers. They require the same culture as the Protea.

(4900) LEYCESTERIA, a genus of Plants belonging to the natural order Rubiaceæ, named after the late Mr. Leycester, Capt. of the Bengal Civil Service, who paid much attention to horticulture in India. The genus consists of only a single species.—*Roy. Oye.*

(4901) LEYCESTERIA FORMOSA, is a native of the Himalaya Mountains, at elevations of from 6000 to 7000 and 8000 feet, in Nepaul and Sirmore, where it grows among oaks and pines, and is therefore well suited to the climate of England, where indeed it may be seen growing in great luxuriance in some gardens, and showing that many others from the same situations are equally suitable to this climate, which is not the case with many shrubby Rubiaceous plants. It forms a large and very showy shrub, with numerous luxuriant smooth and cylindric fistulous shoots issuing from the root, which are of a purplish colour. The leaves are opposite, ovate-lanceolate, and glaucous; the flowers white, with a tinge of purple, arranged in drooping racemes, which are furnished with coloured foliaceous bracts.—*Eng. Cyc.*

(4902) LIBER, the inner bark of the plant, is a layer consisting of woody tissue, cellular substance, and vessels of the latex, forming a compact zone immediately applied to the wood. The woody tissue of which it is composed quickly becomes thick-sided, by the addition of internal ligneous strata, the consequence of which is that such tissue in this part is more tough than elsewhere. Hence it is usually from the liber that are extracted the fibres employed in making cordage or linen-thread: this at least is its source in hemp, flax, the lime-tree, the lace-bark, and the many other Exogens which furnish thread; but in Endogens, which have no liber as the Cocoa-Nut, it is the ordinary woody bundles of the leaves, stem, and husks of the fruit from which the fibre used for ropes is procured. It is said that certain Exogens, such as *Menispermaceæ*, have no liber. ('Comptes Rendus,' v. 393.) In many plants a new layer of liber is formed annually, contemporaneously with a new layer of wood, but this is by no means universal; on the contrary, the oak and the elm increases their liber slowly and irregularly.—*Eng. Cyc.*

(4903) LICHENS. Various species of *Lecanora*, particularly *L. tartarea*, known as cudbear, are used in dyeing woollen yarn. The *Rocella tinctoria* and *fusiformis* furnish the orchil or orchilla weed of commerce, which is sometimes sold as a moist pulp, but usually in the form of dry cakes, known under the name of *litmus*; it produces a fine purple colour. English imports, which have amounted to 6,000 or 7,000 cwts. annually, are derived chiefly from the Canary, Azores, and Cape Verd Islands. Rock orchilla was shown at the Exhibition of 1851; from the Berlingen Isles, from Angola, Madeira and the Cape de Verds. Orchilla weed is very plentiful about the shores of the islands of New Zealand, some being sent from thence to that Exhibition; but from a want of knowledge as to the time at which it should be gathered, and the mode of preparing it for the market, it has not yet become a saleable commodity. The rich varieties of lichens on the rocks and plains of Australia have not been tested, as they ought to be, with Heist's lichen test. Various lichens, and *Rocella tinctoria*, from Tenasserim and other parts of India, have been introduced by the East India Company, and there are many on the mountains of India, to which attention might be directed. In the Admiralty instructions given to Capt. Sir James C. Ross, on his Antarctic voyage, a few years ago, his attention was specially called to the search and enquiry for substitutes for the *Rocella*, which is now becoming scarce. A prize medal was awarded, in 1851, to an exhibitor from the Elbe for specimens of the weed, and an extract of red and violet orchil. Specimens of varieties of the lichens used in the manufacture of cudbear, orchil and litmus, and of the substance obtained, were also shown in the British department, which were awarded prize medals.—Lichen: Several lichens grow on the top of the Dounkia pass as *Cladonia vermicularis*, the yellow *Lecidea geographica*, and the orange *L. miniata*, also some barren mosses. At 18,300 feet, Dr. Hooker found on one stone only a fine Scotch lichen, a species of *Gyrophora*, the "*tripe de roche*" of Arctic voyagers, and the food of the Canadian hunters; it is also abundant on the Scotch alps.—*Hooker, Him. Jour. Vol.* II. *page* 130. Of the lichens several are nutritious, some bitter, some yield to ammoniacal solutions a variety of brilliant colours, and are much used as dye stuffs. They are perennials, spreading in the form of a crust over rocks, trees, or the surface of the earth.—*O'Shaughnessy, p.* 671. The chief lichens employed in the manufacture of orchil and cudbear are the Angola weed (*Ramalina furfuracea*) and Mauritius weed (*Rocella fusiformis*), which comes also from Madagascar, Lima, and Valparaiso, and then bears the distinctive commercial name of the port of shipment.

(4904) LICHEN ODORIFERUS. Borrera asneh, Royle. Is a product of the Himalayas. It is officinal at Lahore. The Hakims administer it in disorders of the stomach, dyspepsia, vomiting, pain in the liver or womb, induration in the uterus, amenorrhœa, calculi, and nocturnal spermatic discharges.—*Dr. Honigberger, page* 299.

(4905) LICHEN ROTUNDATUS, Rottl.

Kull pashie, Tam.	Hinnaey koreish, Arab.
Puthur ka pool, Duk.	Ratipanchie, Tel.

This is a dried Rock Moss which the Tamool practitioners suppose to possess a cooling quality and prepare a liniment with it accordingly.—*Ains. Mat. Med. p.* 86.

(4906) LICUALA, a genus of Palms of the tribe *Coryphinæ* of Martius, so named by Rumphius, from the Macassar name of the species L. *spinosa*, figured by him in 'Herb Amboin.,' i. t. 9, and which is found in the islands of Macassar and of Celebes. Another species, *L. pel-*

tola, is described by Dr. Roxburgh as a native of the mountainous and woody parts near Chittagong, which separates that province from the Birmah territories. Both species are small, with palmate, somewhat fan-shaped leaves, but of little use. Rumphius describes the narrow leaves of this tree as being formed into pipes for smoking tobacco, while the broader are employed for wrapping up fruit, and for other domestic uses. —*Eng. Cyc.* This genus of palms is confined to the tropical parts of Asia, and composed of about a dozen species.—*Seeman.* The different Canes which are imported, are most of them produced by species of Calamus. The walking sticks called "Penang Lawyers," however, are the stems of the small palm, *Licuala acutifida*. The Ground Rattan is distinguished by its straight head and straight and stiff character altogether, as well as by its pale colour; though some are at least an inch in diameter, and others not half that thickness. Some are distinguished by a hard, and others by a soft bark. It is not known whether the slender are of the same species as the thicker kinds, growing in different situations, or from roots of different ages, but *Rhapis flabelliformis* is said to yield the Ground Rattan. The Malacca Cane is supposed to be produced by *Calamus Scipionum*, but said to be imported from Siak, on the coast of Sumatra. Some of these are simply mottled or clouded, others of a brown colour, in consequence, it is said, of their having been smoked. The more slender specimens of these, with the longest internodes, are those most highly valued. —*Seeman.*

(4907) LICUALA. WALKING-CANE PALM. The islands of the Mergui Archipelago yield a small palm, the stems of which are used for walking-sticks, like "Penang Lawyers"; and is probably a species of the same genus that produces those famous canes.—*Mason.*

(4908) LICUALA LONGIPES. STEMLESS LICUALA. This is a nearly stemless palm described by Griffith as remarkable for its dark green foliage. He met with it in the forests south of Mergui.—*Mason.*

(4909) LICUALA PELTATA, Roxb. one of the finest of the species, the "Chatta-pat," of the Assamese inhabits all the woody mountains to the eastward of Bengal, as well as the base of the Himalaya, below Darjeling, Rungpore and Assam, and its large peltate orbicular leaves, though coarser than "Toko pat" of Assam, are used for the same purpose, though only by the lower orders. Nevertheless the demand for them is very great, scarcely a single ploughman, cowkeeper or coolie being without his "*jhapee*" or *chatlah*, (umbrella-hat, made of *chattah*-pat.—*Seeman.* This is also a Sikkim palm.—*Hooker.*
